DUFRENOY, du'fra'nwä', PIERRE ARMAND PETIT (1792-1857). A French geologist and He was born at Sevran, Seine-et- at the Ecole Polytechnique and the Ecole des Mines, was appointed a professor in the latter, and in 1848 became its director. In 1840 he was elected a member of the Academy of Sciences. His principal achievement as a scientist was the execution, in collaboration with Elie de Beaumont, of a geological map of France (1841), the publication of which, from the fact that it was the first prepared of an entire country, was an important event in the learned world. In connection with this work he spent 13 years of exploration in France, England, and northern Spain. He also devised a new system of classification of minerals, based on crystallography. He was a member of the Academy of Sciences and a commander of the Legion of Honor. His writings include: *Voyage métallurgique en Angleterre* (2d ed., 1837-39), with Elie de Beaumont; *Explication de la carte géologique de la France* (1841-48), also with Elie de Beaumont; *un Traité complet de minéralogie*, with atlas (1844-45).

DUFRESNY, du'fra'né', CHARLES RIVIÈRE (1648-1724). A French writer of comedies, born in Paris. He was valet de chambre to Louis XIV and later inspector of the Royal Gardens, in which capacity he introduced many innovations from England. His comedies, *L'Esprit de contradiction* (1700), *Le mariage fait et rompu* (1721), *Le double veuvage* (1701), still enjoy high rank for their brilliant repartee. His *Amusements sérieux et comiques* (1705; 1869) became the prototype of Montesquieu's *Lettres persanes*. His second wife was his washerwoman, whom he married to satisfy the debt he owed her.

DUGANNE, dû-gän', AUGUSTINE JOSEPH HICKEY (1823-84). An American author, born in Boston. He early achieved some reputation as a poet by his *Hand Poems* (1844), a collection of verses published in newspapers. He was of the American, or "Know-Nothing," party, and served in the Civil War as colonel of the 176th New York Volunteers. Subsequently he was active as an author and journalist and for many years was connected with the *New York Tribune*. A list of his works includes the following: *Comprehensive Summary of General Principles* (1845); *The Iron Harp* (1847); *The Lydian Queen* (1848); *Poetical Works* (1856); *Utterances* (1864); *Camps and Prisons* (1865); *The Fight* (1866); *Governments of the World*

DUGAZON, ROSE LEFÈVRE (1755-1821). A French actress, wife of Jean Baptiste Henri Dugazon, whom she divorced soon after their marriage. She was the daughter of a dancing master in Berlin and first appeared on the stage as a dancer at the age of 12, but made her début at the Comédie Italienne in 1774 in a singing part. Two years later she was admitted into the company as "sociétaire" and continued to act in Paris with uninterrupted success for more than 20 years. She was especially successful in her portrayal of such types of character as Jenny in *La dame blanche* and Berthe de Simiane in *Les mousquetaires de*

la reine, and later of young mothers and more matronly types such as Marguerite in *Le pré aux clercs* and the Queen in *La part du diable*. These types of character came to be known as "Dugazons" and "mères Dugazons."

DUGDALE, SIR WILLIAM (1605-86). An English antiquarian and historian, born in Warwickshire. His researches into the early history of Warwickshire and his adherence to the royal cause led to his being knighted and to his holding a number of offices in the College of Heraldry. His greatest work is the *Antiquities of Warwickshire* (1656; 2d ed., 1730), which has been the model for many county histories. Among his other works are: *Monasticon Anglicanum* (1655-73), written in part by Robert Dodsworth; *The Baronage of England* (1675-76); *Origines Juridicales, or Historical Memoirs of the English Laws* (1666); *Short View of the Late Troubles in England* (1681); *The Ancient Usage in Bearing Arms* (1682). Dugdale bequeathed more than 27 folio manuscript volumes, written in his own hand, to the University of Oxford. They are now in the Bodleian Library, the Heralds' College, and the Ashmolean Museum.

DUGÈS, du'zhä', ANTOINE LOUIS (1797-1838). A French naturalist, born at Mézières (Ardennes). He was professor of pathology at Montpellier until his death. During the last two years of his life he was rector of the university. He was a skillful surgeon and one of the foremost zoölogists of the time. He investigated the anatomy of spiders, moths, frogs, and vertebrata. His publications include: *Recherches sur les maladies les plus importantes des nouveaunés* (1821); *Manuel d'obstétrique* (1826; 3d ed., 1840); *Recherches sur les batracchiens* (1834); *Physiologie comparée* (1838-39).

DUGGAR, BENJAMIN MINGE (1872- . . .). An American plant Gallien, Ala. He studied schools, ma Polytechnic Institute (B.S., and Cornell (Ph.D., 1898), and in Germany, Italy, and France. As a specialist in botany, he held various positions in experiment stations and colleges until 1901, when he was appointed the Bureau of Plant Industry, Department of He was professor of botany at of Missouri from 1902 to 1907 and thereafter held the chair of plant physiology at Cornell. He was vice president of the Botanical Society of America in 1912 and 1914. His publications include *Fungous Diseases of Plants* (1909), and *Plant Physiology* (1911), besides bulletins of the United States Department of Agriculture.

DUGMORE, ARTHUR RADCLYFFE (1870- . . .). An English naturalist and animal photographer, born in Wales and educated at Elizabeth Guernsey, England, and at Turrell's School. studied printing in Naples and and in 1889 came to the United States, where he continued his art work and also studied natural history. In 1898 he began to make careful use of the camera as a means of securing lifelike portraits of wild birds and animals. His skill in this work soon made him famous and gave him material for numerous magazine articles and several books of first-rate importance to the literature of natural history, because of the accuracy of his observation and the remarkable fidelity of his photographic illustration. His most ex-

traordinary achievements with the camera are preserved in his book entitled *Camera Adventures in the African Wilds* (1910), which contains his experience (many of them extremely hazardous) in photographing African big game. Another very valuable as well as interesting volume is *The Romance of the Newfoundland Caribou* (1913), in which he gathered the results of nine seasons of patient and successful camera hunting of that wary animal. His other works include: *Nature and the Camera* (1902); *Nature Portraits* (1903); *Bird Homes* (1904); *Wild Life and the Camera* (1912).

DUGONG' (Malay *dūyong*, Javanese *duyung*). A sirenian or "sea cow" (q.v.) of the family Halicoridae and genus *Halicore*, or, according to some authors, *Dugongia* and *Dugong*. It is distinguished by its well-developed dentition and especially by the fact that in the males the incisors of the upper jaw are elongated almost into tusks; also by the fact that the tail is forked or crescent-shaped, and the swimming paws are destitute of any vestiges of nails. In general form it much resembles the manatee (q.v.). The skull is remarkable for the sudden bending downward of the upper jaw almost at a right angle. The upper lip is large, thick, and fleshy, covering the prominent incisors and forming a kind of snout, "something like the trunk of the elephant cut short across." The eyes are very small and are furnished with a third eyelid or nictitating membrane. The skin is smooth and thick, and that of the Australian species yields a valuable oil, used sometimes in medicine, the demand for which has caused the animal to be almost exterminated in that region. The dugong is marine, inclined to gather near the shore in herds, which formerly sometimes numbered hundreds, and browses, with its head beneath the water, on the algae which grow on submarine rocks in shallow seas. It is usually pursued in boats and speared. The female produces one young one at a birth and shows an affection for it which is proverbial among the Malays. When the young one is taken, the mother is easily secured. Its habit of raising its round head out of the water and of carrying the young under the fore fin seems to have given rise among the imaginative early voyagers in the Indian Ocean, to the half-human beings, half human and half fish, in allusion to which the name Sirenia was bestowed by Illiger on the order. (See MERMAID.) According to Rüppell, it was with the skin of the dugong of the Red Sea that the Jews were directed to veil the tabernacle, and not "badger" skins, as translated in the Authorized Version of the Bible. Three species of dugong are known—one from the vicinity of Australia (*Halicore australis*), one from the Red Sea (*Halicore tabernaculi*), and one from the East Indies (*Halicore dugong*). See MANATEE and EXTINCT ANIMALS; and for fossil forms allied to the dugongs, see HALITHERIUM.

DUGOUR, JARDY. See GOUROFF.

DUGUAY-TROUIN, du'gā' trō'ān', RENÉ (1673-1736). One of the most celebrated privateers and naval officers of France. He was born at Saint-Malo, of a family of rich ship-owners, and, after some schooling at Caen, embarked in a frigate at the age of 13. At 15 he was commander of a privateer and began a marvelous series of exploits, capturing large fleets of transports and attacking and defeating ships of the line. The Channel, the coasts of Ireland

and Holland, the fishing banks of Spitzbergen, and the Spanish Main were the scenes of his activity. As a reward for his services, Louis XIV gave him the command of a frigate in the royal navy. Captured and taken to England, he escaped and continued his destructive activity. In 1707 he attacked an English merchant fleet and its convoy, sank one frigate, and captured three others. In 1709 he destroyed the Brazilian fleet off the port of Lisbon. In 1711 he captured Rio Janeiro after a bombardment of 11 days and extorted a ransom of \$300,000. For his services Louis XIV knighted him and made him successively *chef d'escadre*, lieutenant general, and naval commandant at Brest. Consult: his *Mémoires* (Paris, 1740); Richer, *Vie de Duguay-Trouin* (ib., 1879); the *Journal* of La Landelle (ib., 1876) and De P. (ib., 1890).

DU GUESCLIN, du gāk'lān', BERTRAND (c.1320-80). A constable of France, the most celebrated French soldier of his age. He was born at the castle of Motte-Broons, near Dinans, Brittany, and entered the service of Charles of Blois by 1342. In 1354 he was knighted and went with the lords of Brittany to England to secure the release of his captive master. He gallantly relieved Rennes, besieged by the Duke of Lancaster, in 1356, and by his help the city held out until the truce of Bordeaux, in June, 1357. He soon took service under the French King and after several brilliant actions was made lieutenant of Normandy and Count of Longueville in 1364. At the battle of Auray, in 1364, he was taken prisoner, but was ransomed, and, becoming commander of the Grand Companies (see CONDOTTIERE), led them into Spain, where he aided Henry of Trastamare in his war against Pedro the Cruel, and was made Constable of Castile. In 1367 he was taken prisoner by the Black Prince, then in alliance with Pedro the Cruel. Being again ransomed, he again fought for Henry, who received the kingdom in 1369, and Du Guesclin for his great services was made Duke of Molinas. In 1370 he was made Constable of France and for 10 years was active and successful in driving the English from the south and west of the country. In 1373 he seized and held most of the strongholds in the Duchy of Brittany. He died while besieging the fortress of Châteauneuf de Randon (q.v.). It is said that before his death the garrison had already promised to capitulate, and that their commander led them out and placed the keys of the castle upon the coffin of the Constable. He was buried in the church of Saint-Denis. Du Guesclin was ugly in appearance, brutal in his manners, and uneducated; but he had great natural abilities and profited by his long experience. Consult: Froissart, *Chronicles*; Luce, *Histoire de Bertrand du Guesclin et de son époque* (Paris, 1876); Stoddard, *Bertrand du Guesclin, Constable of France* (London, 1897).

DUHAMEL, du'ā'mēl', JEAN MARIE CONSTANT (1797-1872). A French mathematician, born at Saint-Malo. He occupied chairs in the Ecole Polytechnique, the Faculté des Sciences, and the Ecole Normale Supérieure. Besides numerous memoirs on mathematics, he published the following works: *Problèmes et développements des mathématiques* (Paris, 1823); *Cours d'analyse* (ib., 1841-47); *Éléments de calcul* (1856-57; 4th ed. by Bertrand, 1887); *Cours de mécanique* (1845-46); *Des méthodes dans les sciences de raisonnement* (5 vols., ib., 1866-72;

2d ed., ib., 1878-86). "Duhamel exerted a great influence by the clearness and precision of his teaching. Possessed of a mind more exact than profound, devoting himself especially to perfecting the methods by which science progresses, he had the honor of being the first to give a rigorous demonstration of the principles upon which the infinitesimal calculus rests." (Paul Tannery.)

DUHAMEL, JOSEPH THOMAS (1841-1909). A Canadian prelate. He was born in Contrecoeur, studied at St. Joseph's College, Ottawa, was ordained in 1863, and became Bishop of Ottawa in 1874 and Archbishop in 1886. Through his efforts the college at Ottawa obtained the powers of a Catholic university.

DUHAMEL DU MONCEAU, du'a'mêl' du mōn'sō', HENRI LOUIS (1700-81). A French botanist. He was born in Paris and devoted himself to botany and arboriculture. He discovered that a disease of the saffron plant is caused by a parasitic fungus attacking the roots. In company with Buffon, and also independently, he experimented in vegetable and animal physiology. He was also interested in nautical matters and during the latter part of his life was engaged as inspector general of marine for the channel district of the French coast. On account of his researches in arboriculture he was elected a member of the Academy of Sciences of Paris. His most important publication is *Traité des arbres et arbustes, qui se cultivent en France en pleine terre* (2 vols., Paris, 1755; 2d ed., known as *Nouveau Duhamel*, ed. Etienne Michel and others, 7 vols., Paris, 1801-19). Other publications on arboriculture appearing between 1757 and 1783 were *Traité des arbres fruitiers* and *Pomona Gallica*.

DUHM, BERNHARD LAWARD (1847-). A German Protestant biblical scholar, born at Bingham, Hanover. He was educated at Göttingen and taught there from 1877 to 1889, when he went to Basel as professor of Old Testament theology. Among his brilliant works are: *Theologie der Propheten* (1875); *Ueber Ziel und Methode der Theologie* (1889); *Kosmologie und Religion* (1892); *Das Geheimnis in der Religion* (1896); *Die Entstehung des Alten Testaments* (1897-1906); *Das Kommende Reich Gottes* (1909; Eng. trans., by Duff, 1911); translations in the metre of the *Old Testament* of Job (1897), the Psalms (1899), *Isaiah* (1903), and *Habakkuk* (1906); and commentaries on these books and on the 12 minor prophets (1911). In *Isaiah* he attempted to separate certain passages in chaps. xlii, xlix, l, lii, and liii as "cervant" songs; and in *Jeremiah* he set up elaborate metrical tests of style.

DÜHRING, dü'ring, EUGEN KARL (1833-). A German philosopher and economist. He was born and educated in Berlin. After practicing law for three years he was compelled to abandon that profession in 1854 because of an affection of the eye which eventually resulted in blindness. He was lecturer on philosophy and political economy at the University of Berlin from 1864 until 1877. His philosophical standpoint is often called materialistic, but the epithet does not do justice to his views. He believed in the competency of reason to comprehend reality. Actual reality as it appears in our experience is for him the only real existence and is thoroughly rational. He strenuously denies the Kantian doctrine that the categories (q.v.) of time and space have

only subjective validity. In ethics he is an opponent of egoism and pessimism. His writings, however, are full of bitter personalities. In 1877 he was deprived of the privilege of lecturing at the University of Berlin because of his violent attacks upon his colleagues in his works. His economic works frequently show the influence of Henry C. Carey. Among his most important publications are: *Natürliche Dialektik* (1865); *Der Wert des Lebens* (5th ed., 1894); *Kritische Geschichte der Philosophie* (4th ed., 1894); *Kritische Geschichte der allgemeinen Principien der Mechanik* (3d ed., 1887), considered one of the best works on that subject; *Kritische Geschichte der Nationalökonomie und des Sozialismus* (3d ed., 1879); *Die Judenfrage als Frage des Rassencharakters* (5th ed., Berlin, 1901); *Sitte und Kultur der Völker* (4th ed., 1892); *Kursus der Philosophie* (1875); *Logik und Wissenschaftstheorie* (1878); *Die Grossen der modernen Litteratur popular und kritisch nach neuen Gesichtspunkten dargestellt* (1893); *Logik und Wissenschaftstheorie* (1905); *Robert Mayer* (1904); *Soziale Rettung durch wirkliches Recht statt Raubpolitik und Knechtsjuristerei* (1907). Consult Doll, *Eugen Dühring: Etwas von dessen Character, Leistungen und reformatorischem Beruf* (1893).

DUHRING, dü'ring, LOUIS ADOLPHUS (1845-1913). An American dermatologist, born in Philadelphia, Pa. He graduated in the medical department of the University of Pennsylvania in 1867 and in 1867-68 was a resident physician of the Philadelphia Hospital. In 1868-70 he studied dermatology in European hospitals and in the latter year established in Philadelphia a dispensary for cutaneous diseases. He was appointed clinical lecturer on dermatology at the University of Pennsylvania in 1871 and professor of dermatology of the skin in 1876. His publications include an *Atlas of Skin Diseases* (1876) and a *Practical Treatise on Diseases of the Skin* (1878), the latter translated into Italian, Russian,

DUIFFOPRUGGAR, dwé'fō-pru'gār, CASPAR (1514-71). One of the first-known violin makers in Europe. He was born at Freising, in Bavaria, but nothing authentic is known of his early career, except that his father was Tieffenbrucker; the change to the one by which he is best known having been caused by his residence in Italy and France, in which latter country he was finally naturalized (1559). He was long reputed to have been the first maker of violins in Europe, but this claim has been seriously challenged by Dr. Coutagne in his *Gaspard Duiffopruggart et les luthiers lyonnais du XVIe siècle* (Paris, 1893). This authority claims that all the instruments known as Duiffopruggar violins were really the handiwork of Vuillaume, who is supposed to have got his ideas from a *viola de gamba* made by Duiffopruggar.

DUIKER, or **DUYKER**, dī'kēr or dōi'kēr (Dutch, diver). 1. One of the small African antelopes, or duikerboks, of the genus *Cephalophus*, often but confusingly, called duikers by English residents and sportsmen; especially *Cephalophus grimmii*. They abound in forested and bushy districts, moving about in small parties, leaping among the rocks, and dodging into and through the thickets with surprising agility, while their plain colors render them practically invisible when quiet.

All have very convex foreheads and very large eyes and ears, between which, in both sexes, rise two little spike horns and a median tuft of stiff hairs. All these antelopes feed largely on berries and small fruits, and their flesh has an excellent flavor. The typical species known in the north as deloo is very common in southwest Africa. It is about 26 inches high, variable in color, and often tamed as a pet. The redbuck of Natal differs mainly in its reddish bay color. The Natal jungles also contain the diminutive bluebuck, or pygmy antelope (*Cephalolophus monticola*), which is the smallest of its score or more of species in this genus, standing only 13 inches high; they are smaller and lighter in build than a hare and are of a bluish mouse color." The hegoleh, or madoqua (*Cephalolophus abyssinicus*) of Abyssinia or Beni Israel (q.v.); the philantomba (*Cephalolophus maxwelli*) of Sierra Leone; the wood antelope of the west coast (*Cephalolophus sylvicultor*); and the zebra antelope (*Cephalolophus dorae*), also of West Africa, are notable species—the last-named of large size and golden brown in color, striped with black bands across the back and loins. Consult: Schweinfurth, *Heart of Africa* (Leipzig, 1878), and other books of African exploration; also, Randall, *Proceedings Zoological Society of London* (London, 1895); Sclater, *Mammals of South Africa* (ib., 1900); Lydekker, *Game Animals of Africa* (ib., 1908). See Colored Plate of ANTELOPES. 2. In South Africa, a diving bird, as a cormorant or the darter (*Plotus levillanti*), the latter illustrated in the Plate of FISHING BIRDS.

DUILIAN COLUMN. A column erected in the Forum at Rome in honor of the naval victory of Gaius Duilius (q.v.) over the Carthaginians. The name *columna rostrata* (rostral column), the class to which this belongs, was given to columns commemorating naval victories (from *rostrum*, the beak of a ship), as they had on each side projections in the form of such beaks, which were usually the actual beaks of the captured vessels of the enemy. Michelangelo's restoration of this column is in the Palazzo de' Conservatori, on the Capitoline Hill. Its pedestal retains a portion of the inscription which was on the column erected in Imperial times, to take the place of the original, which had been destroyed by lightning.

DUILIUS, δούλιος, GAIUS. Roman consul in 260 B.C. and victor in the great naval battle against the Carthaginians off the promontory of Mylae, northwest of Messina, Sicily. In the spring of 260 the Romans launched a fleet of 120 vessels. Duilius' colleague, Gnaeus Cornelius Scipio, was first appointed commander. Having attempted to capture Lipara with the first 17 vessels prepared, he was blockaded by the Carthaginians in the harbor of that island and was captured with his entire squadron. Duilius thus succeeded to the command and with the main Roman fleet met the enemy advancing from Panormus. The inferiority of the Roman vessels and crews was counterbalanced by the successful use of a boarding bridge which Duilius had invented. The Roman vessels ran closely alongside the enemy, dropped the bridge, and thereby grappled the ships together. The conditions thus approximated those of a conflict on land. Of the Carthaginian fleet Duilius sank or captured 50 galleys, includ-

ing the commander's flagship, taken from Pyrrhus. The immediate effect of this victory was, of course, to turn the tide of the war, but its ultimate result was far greater. Rome became forthwith a naval power, able to dispute with Carthage the supremacy of the Mediterranean. Duilius celebrated the first naval triumph in Roman history. He was honored by a memorial column. See COLUMNA ROSTRATA: DUILIAN COLUMN.

DUISBURG, düs'is-burk. A town of Rhenish Prussia, situated about 15 miles north of Düsseldorf, between the Ruhr and the Rhine, with both of which it is connected by a canal (Map: Prussia, B 3). In 1905 the neighboring cities of Ruhrort and Meiderich were incorporated with it, and their joint harbors, including the Rhine, Ruhr, and artificial harbors, are said to comprise the largest river harbor in the world. Among its numerous churches that of St. Salvator, a handsome Gothic edifice of the fourteenth century, contains some beautiful mural decorations and the tomb of the famous geographer Mercator. It has a beautiful new rathaus, built in 1901, and a museum. The streets are well laid out, and all modern conveniences are controlled by the municipality. The manufactures of Duisburg grew with the improvement of its water front. It is the central mart of the Westphalian coal and iron trade and in turn has huge imports from Spain, Sweden, Russia, the United States, and countries of North and South America. It has iron foundries, blast furnaces, machine works, steel and brass works, important chemical works and factories manufacturing malt liquors, asphalt, glue, varnish, furniture, tobacco, soda, sulphuric acid, soap, starch, and sugar. In addition to the products manufactured in the city, the exports include those of the surrounding country, viz., iron ore, coal, and grain. The total tonnage entering and leaving in 1912 amounted to 20,570,000. Pop., 1900, 92,729; 1905, 192,346; 1910, 229,483. Duisburg is an ancient town. It was the Castrum Duburges of the Romans and the Dispargum of the Franks. It was strongly fortified by Charlemagne. In the thirteenth century it became a member of the Hanseatic League, afterward a free town of the Empire, but later a part of the territory of Cleves, but at the close of the Napoleonic wars it was handed over to Prussia.

DUJARDIN, düzhär'dän', FELIX (1801-60). A French naturalist born at Tours, France, April 5, 1801. He studied at Tours and in Paris and was later professor of zoölogy in the Faculté de Rennes. He wrote many works on worms, insects, etc., including *Histoire naturelle des infusoires* (1841), and *Histoire naturelle des helminthes* (1844). He died at Rennes, April 8, 1860.

DUJARDIN, KAREL (1622-78). A Dutch landscape, animal and genre painter, born probably in Amsterdam. He was a pupil of Nikolaas Berchem and was influenced by Potter, but went to Italy while still young. He did not return to Holland for many years. His pictures have more of the Italian than the Dutch atmosphere. They usually represent landscape, with figures and animals painted with freshness and animation and broad and able technique. This is especially true of his genre scenes with horsemen; but he also painted portraits and religious subjects, the

latter with little success. Dujardin's pictures were frequently imitated. The best of them are in the Louvre in Paris, and one of these, "The Charlatans" (1657), is his masterpiece. He is also well represented in the Rijks Museum, Amsterdam, where there is a fine portrait of himself; in Brussels, Berlin, and the National Gallery, London. He left some etchings of animals and landscapes.

DUKAS, PAUL (1865-). A French composer, born in Paris, Oct. 1, 1865. He studied at the Conservatory under Dubois, Mathias, and Guiraud, and with his cantata *Velléda* won the second Prix de Rome. He attracted general attention with his orchestral work *L'Apprenti Sorcier* (1897), since which he has been regarded as one of the leaders of the modern French school, and one whose influence is second perhaps only to that of Debussy. He also wrote a symphony and three overtures, *King Lear*, *Götz von Berlichingen*, *Polyeucte*, and his compositions for piano possess unusual merit. His opera *Ariane et Barbe bleue*, on a text by Maeterlinck, scored a great success in Paris in 1907. It soon found its way into Germany and Austria and was also heard in the United States (Metropolitan Opera House, 1911).

DUKATO, CAPE. See CAPE DUKATO.

DUK-DUK, duk/duk'. A secret, but not essentially mystic, social organization of the littoral Melanesians on St. George's Channel in the Bismarck Archipelago and most highly developed on the northeast coast of Gazelle Peninsula, New Pomerania. Though the Duk-duk plays a very large part in the life of the community, and similar societies are common in the Solomon Islands to the south and elsewhere in New Pomerania, this organization appears to be no older than a century or at most five generations. The central spot of Duk-duk ceremonies and initiations is a clearing (*taraiu*) in the forest, hidden from chance passers by a curtain of undergrowth; temporary areas for public processions for the masks of the participants are formed by raising a screen of mats. The germ sense of all rites of initiation is that the mother principle, the Tubuan, gives birth to her son, the Duk-duk, personifying the postulant for membership, a theme common to primitive religions as the new birth. The Tubuan is a female spirit, a purtenance of some man of wealth or rank, and each has her distinctive name; the right to the Tubuan is hereditary or may be purchased by large amounts of shell money. The garb in ceremonies distinguishes the symbolic mother and son: they are clad alike in a bushy cloak of leaves covering the trunk; the Tubuan wears a mask covering the whole head and extending in a short cone crowned with a thick bunch of cockatoo feathers; the Duk-duk, a mask with longer and sharper cone decorated with pieces of carved wood, wreaths of feathers, and other bright adornment. Although the organization bears evidence of matriarchy in its membership is forbidden to women, who may not even approach the *taraiu*, with the exception of a few old crones who render certain minor services. Induction into the society entails the older members which frequently inflict lasting harm by the payment of shell money, and lavish feasts. The beatings at times of public feasts extend to all uninitiated

onlookers, but in that case the strokes are rather ceremonial than lasting, since the clubs are dried banana stalks which inflict more sound than fury. The payment for initiation sometimes amounts to 100 fathoms of shell money, the price of at least 10 young and good wives. This charge is so heavy that the junior members of the society are obliged to work at productive labor for no small term of years in order to satisfy the debt. The advantages accruing from membership are that the member has support in time of need, enjoys the pleasure of the social club, and may deal high-handedly with uninitiates. The songs of the society are frequently unintelligible, but that is not a character in particular, for many savage chants have endured beyond their meaning. The society is common speech some-

by strange terminations after the manner familiar in hog Latin. Consult: the first account of the Duk-duk in Wilfred Powell, *Three Years among the Cannibals of New Britain* (London, 1884); Graf von Peil, in *Journal of the Royal Anthropological Institute* (ib., 1897); Schurtz, *Altersklassen und Männerbünde* (Berlin, 1902); Parkinson, *Dreissig Jahre in der Sudsee* (Stuttgart, 1907); George Brown, *Autobiography* (London, 1908); id., *Melanesians and Polynesians* (ib., 1910).

DUKE (Fr. *duc*, It. *duca*, Sp., Portug. *duque*, MGk. *δούξ*, *doux*, from Lat. *dux*, from *ducere*, to lead). A title given among the Romans to a general commanding a single military expedition and holding no other power than that which he exercised over his soldiers. The designation first arose in the early part of the second century and entered into the official hierarchy of Rome very soon after. Upon the separation of the civil and military functions in the fourth century the duke became commander of all the troops cantoned in a single province. In an Imperial almanac edited about the year 400, 25 dukes are mentioned in the whole extent of the Empire, 13 in the east and 12 in the west. The prerogatives of the dukes at this time were extensive. At first they were judges in all military trials within their jurisdiction, but, in Italy at least, they ended by centralizing in their own hands all the civil and military powers. The Byzantine duke was chief of the provincial soldiers, named the civil and military officers of the lower grade, and heard appeals from their judgments. He held the civil and criminal jurisdiction and even sat with the bishop to hear ecclesiastical cases. He protected the church and had important functions in its administration. Finally, he took a part in managing the financial affairs of the province. See EXARCH.

In France, under the Merovingian rule, the dukes became the highest officers in the provincial administration. At first they had been only military chiefs, but about the seventh century they gained the same military and judicial powers as the counts. (See COUNT.) The latter, however, governed but a single *comitatus*, or county, while the duke's administration extended over several *comitatus*. When the King appointed a duke it was frequently for the purpose of suppressing a revolt of the counts or of the defense of the frontier. There was a ducal tribunal, but it was not always superior to that of the count. Apparently the tribunal was held in special cases by the order of the King.

The possibility of conflicting powers caused frequent strife between the dukes and counts. The dukes did not differ greatly from the counts, but as the central power grew weaker in this period, the power of the dukes increased. The dukes acquired regal rights and by the end of the tenth century had made their tenure hereditary in France. They had acquired independence and were no longer held to the central power except by the weak bond of vassalage. In general, the duke assumed all the rights which the King could not retain for himself. Towards the close of the twelfth century royalty strove to regain the rights of which it had been robbed. The dukes, however, retained their powers longer than the lesser dignitaries. Some duchies were reunited to the crown, but new ones were created, so that the number increased as their size decreased. Gradually, however, the powerful ducal sovereignties were extinguished, and by the early part of the sixteenth century the King had no rival to fear. The duchies granted after the thirteenth century, as a general thing, enjoyed none of the ancient privileges of independent sovereignty. The dukes were only the first subjects of the realm. Titles of nobility in France were abolished by the Constituent Assembly during the Revolution, but were restored by Napoleon, and the ducal title was conferred on his marshals. Several ducal peers were created by Louis XVIII and Charles X. In Germany the dukedom passed through phases somewhat similar to those which it had exhibited in the earlier history of France. What is peculiar to the position of the nobility of Germany will be found under GRAF.

Dukes, in the older European sense, do not appear ever to have existed in England. The title seems not to have been known earlier than the reign of Edward III, although "earl" was sometimes translated into Latin as *dux*, even before the Norman Conquest; and from the first it was a mere honorary distinction. The Black Prince, who was created Duke of Cornwall in 1337, was the first English duke. In 1351 Henry, the King's cousin, was created Duke of Lancaster, and when upon his death his daughter was married to John of Gaunt, the King's fourth son, the title was transferred to him, his elder brother Edward made Duke of Clarence. In the reign—that of Richard II—the two younger sons of Edward III were created, the one Duke of York, and the other Duke of Gloucester. The dignity was thus, in the first instance, confined to the royal house. But the families of Holland and Mowbray very soon received the same title, and one of the Beauforts, an illegitimate son of John of Gaunt, was raised to the peerage with the title of Duke of Exeter. In the reign of Henry VI the title was granted more widely, and there were at one time 10 duchesses in his court. The Staffords, Beauchamps, and De la Poles belonged to this period. King Henry VIII created only two dukes—one, his illegitimate son, whom he made Duke of Richmond; and the other, Charles Brandon, who married his sister Mary and was made Duke of Suffolk. Queen Elizabeth found only one duke when she came to the throne—Thomas Howard, Duke of Norfolk—attainder or failure of male issue having extinguished the rest of them. After the attainder and execution of the Duke of Norfolk, there was no duke in England, except the

King's sons, till Ludovic Stuart, a relative of the King, was made Duke of Richmond in 1623. In 1623, also, Villiers was made Duke of Buckingham, and the Restoration Charles II raised him to the rank of dukes of Somerset, and created Monk Duke of Albemarle. But the custom of conferring this dignity on the illegitimate sons of the monarch was still adhered to, as in the case of the Duke of Monmouth, who was the illegitimate son of Charles II, and the Duke of Berwick, son of James II. Of the existing dukes, besides the descendants of Charles II, there are only three families whose titles date from before the revolution of 1688, the Dukes of Norfolk, Somerset, and Beaufort. William and Anne, by their marriages, raised a very considerable number of the first sons of peers to the rank of duke, and changed the character of that dignity; and there were 26 dukes in the House of Lords in addition to the dukes of the royal blood. The ducal coronet, as now worn, has eight golden leaves of a conventional type, set erect upon a circlet of gold. The stalks of the leaves are so connected as to form them into a wreath. Consult Cheruel, *Dictionnaire historique des institutions, mœurs et coutumes de la France*, vol. i (4th ed., Paris, 1874), and Debrett, *Peerage, etc.* (London, 1912).

DUKE, JAMES B. (1857–). A leading American tobacco manufacturer. He was born near Durham, N. C., and became a member of Duke Brothers & Co., manufacturers of smoking tobacco, and, after this firm was absorbed by the American Tobacco Company in 1890, president of the latter. He was chosen president also of the Continental Tobacco Company (incorporated 1898) and of the Consolidated Tobacco Company (incorporated 1901), and chairman of the board of directors of the British-American Tobacco Company, Ltd. In addition he held directorates in many other corporations.

DUKE, JOHN. See COLERIDGE, JOHN DUKE, BARON.

DUKE HUMPHREY'S WALK. The middle aisle of old St. Paul's, London, where the tomb of Duke Humphrey (see HUMPHREY, THE GOOD DUKE) is said to be. The old saying of "dining with Duke Humphrey" was in allusion to persons who walked there during dinner time.

DUKE OF EXETER'S DAUGHTER. A nickname applied in the fifteenth century to an English instrument of torture resembling a rack. It was erected by the Duke of Exeter (hence its derisive name), the Duke of Suffolk, and other ministers of Henry VI who wished to introduce into England the Roman civil law. But it was never used—indeed its use, judges decided, would be unconstitutional—so it was put away in the Tower of London, where it now is.

DUKE OF GUISE, THE. A tragedy, of political significance, by Dryden and Lee, published in 1682 and directed against the Whiggism of Shaftesbury and his followers.

DUKE OF YORK'S SCHOOL. OR ROYAL MILITARY ASYLUM. A school for the education of the sea, by Frederick, Duke of York, in 1801–03, for the support and education of soldiers' orphans. Originally girls as well as boys were admitted, but the admission of girls was discontinued after some years' trial. The institution is supported by parliamentary grant and is under the control of a board of commissioners. Boys leaving school in many cases

enter the army or are apprenticed to trades. There are some 500 boys in the school.

DUKHOBORTSY, du'kō-bōrt'sī, or DUKHOBORS (Russ., spirit wrestlers, from *dukhū*, spirit + *boroti*, to overcome, to fight; so called from the denial by the sect of the divinity of the Holy Ghost). A Russian religious sect dating from 1733 and formally founded in Kharkov about 1740-50. It increased in numbers under Kolesnikov in the government of Ekaterinoslav (1750-75) and under Kapustin in Tambov (1755-85). This rapid growth caused governmental persecutions in 1793-94 and 1797-1800, but Commissioner Lopukhin's favorable report of 1801 moved the government, on his recommendation, to settle the Dukhobortsy on the bank of the river Molochnaya in Taurida. A large tract of fertile land and a comparative immunity from official annoyances brought a period of thrift and prosperity to this religious community. About 1819 the government resumed hostile measures, which culminated in their deportation to Transcaucasia in 1837. Pobiedonostsev's policy of bringing all religious elements of the Empire into conformity with Greek Catholicism was responsible for the severities which attracted the world's attention to this sect in the nineties. After long petitioning, many thousands were allowed to leave for Cyprus and Canada.

In the fall of 1902 the sect in Canada suffered great hardships. They felt inspired to seek the Christ and set out across the bleak stretches of Manitoba, regardless of all personal discomfort. The cold was intense, and many fell by the way. At length, urged by a spirit of humanity, the government insisted on their returning to their homes. The growth of this society is slow. Canada now harbors over 10,000 obors.

Their religious views are simple and handed down by oral tradition, which they significantly call the "Book of Life." Christ was only a man of superior godlike intellect, and his soul has migrated into many mortals. Kolesnikov and Kapustin among others. All people are equal and, being children of God, cannot do wrong; hence there is no need of rulers. Worshiping God in the spirit, the church, with all its agents and formalities, seems entirely superfluous to them. They therefore do not visit churches, considering that wherever two or three persons, united by a common religious tie, gather for worship, there is a church. Praying inwardly at all times, they come together for prayer meeting on certain fixed days, when every one is regarded as a bearer of the divine Spirit. In this and other respects they very much resemble the Society of Friends. They accept the Ten Commandments literally and of the Bible "only the useful" portions, interpreting the rest allegorically. They have no icons, confession, or ceremonies at marriages, which they contract on their own. In private life wives and husbands and brothers, while parents are addressed as "old man" or "old woman." The plenary power of a Dukhobor community is vested in the assembly of elders. Consistent nonresistants, they are opposed to wars of any kind, nor do they sanction the killing of any of God's creatures for food or sport. As members of society, they are generally conceded to be quiet, sober, and hard-working. They belong exclusively to the peasant class.

Consult: Novitsky, *The Dukhobortsy: Their History and Religious Beliefs* (2d ed., Kiev, 1882, in Russian); Tchertkoff, *Christian Martyrdom in Russia* (Toronto, 1899); Elkinton, *The Doukhobors* (Philadelphia, 1903); Maude, *A Peculiar People, the Doukhobors* (New York, 1904).

DU'KINFIELD. A municipal borough of Cheshire, England, on the Tame, 5 miles east of Manchester. It has large cotton factories, iron foundries, fire-brick and tile works, and collieries. The town was incorporated in 1899. It owns its gas works and, with the neighboring town of Ashton-under-Lyne, owns its water supply and maintains a cemetery. It has established a fire department and acquired a technical school and free library. Pop., 1901, 18,929; 1911, 19,426.

DULAG, dōō-lig'. A town of Leyte, Philippines, near the foot of Manacagan Mountain, situated on the east coast of the island, 22 miles from Tacloban. There are large sulphur deposits in the vicinity. Pop., 1903, 14,884.

DULANGAN, dōō-lān'gān, or GULANGANE. A wild Malayan people, pure and mixed, in Davao Province, Mindanao. See PHILIPPINES.

DULANY, DANIEL (1686-1753). A colonial lawyer of Maryland. He was born in Ireland, emigrated to Maryland about 1700, was admitted to the Maryland bar in 1710, became a member of the Council of State, and was for some years commissary general of the Province. He wrote a pamphlet entitled *The Right of the People of Maryland to the Benefit of English Laws*.

DULANY, DANIEL (1721-97). The foremost lawyer in Maryland during the Colonial period, son of the preceding. He was born in Annapolis; was educated at Eton College, Cambridge University, and the Temple, England; was admitted to the bar of Maryland in 1747 and soon gained the reputation, both in England and in America, of being one of the greatest lawyers of his time. He was deputy commissary and commissary general from 1754 to 1761, was a member of the Provincial Council from 1757 to 1775, and was Deputy Secretary and Secretary of Maryland from 1761 to 1773. In 1765 he wrote a powerful pamphlet against the Stamp Act, entitled *Considerations on the Propriety of Imposing Taxes on the British Colonies, for the Purpose of Raising a Revenue, by Act of Parliament*. Though published anonymously, it was immediately recognized as his and was later published under his name. The best argument against arbitrary taxation hitherto written, it attracted widespread attention, had a tremendous influence both in America and in England, and formed the basis of Pitt's great speech in 1766 against the Stamp Act. Dulany consistently opposed the radical measures of the Patriot party, refused to take any part in the Revolution, and in consequence lost, by confiscation, nearly the whole of his vast estates. Consult an article by J. H. B. Latrobe, in the *Pennsylvania Magazine of History and Biography*, vol. iii (Philadelphia, 1879), and Tyler, *Literary History of the American Revolution* (New York, 1897).

DULAURE, du'lōr', JACQUES ANTOINE (1755-1835). A French publicist and historian, born at Clermond-Ferrand. He studied in Paris and afterward became engaged in several engineering projects, one of which involved the construction of a canal between Bordeaux and Bayonne. He

was editor of the *Evangelistes du Jour* and developed an extraordinary journalistic activity during the Revolution. In 1792 he was elected a member of the National Convention and became identified with the Girondists until the downfall of that party. As one of the Council of Five Hundred, he devoted himself chiefly to the improvement of the educational system and afterward became one of the bitterest opponents of Napoleon, until the appointment of the latter to the Consulate, when he retired from politics. He was not only a distinguished legislator, but an inventor of considerable ability, as attested by the ingenious instrument known as the pantograph, which he devised. His publications include: *Histoire abrégée de tous les cultes* (1825); *Description des principaux lieux de France* (6 vols., 1788-90); *Histoire civile, physique, et morale de Paris* (7 vols., 1821, frequently reprinted; continued by Leynadier, 5 vols., 1862, and by Rouquette, 1875 et seq.); *Esquisses historiques des principaux événements de la révolution française* (6 vols., 1823-25; frequently reprinted), a history of the French Revolution to the restoration of the Bourbon dynasty; *Histoire de la révolution française depuis 1814-30*, in collaboration with Vierre and others (8 vols., 1834-41; frequently reprinted).

DUL/CAMA'RA. See BITTERSWEET.

DUL/CE DO'MUM. A school song of Winchester School, England, said to have been composed by a boy detained at the school during the Whitsuntide holidays. It dates from the eighteenth century. It is sung by the students in procession on the evening before the holidays.

DULCE Y GARAY, dōol'thá è gá-rí', DOMINGO, MARQUIS OF CASTELL-FLORIT (1808-69). A Spanish soldier and governor-general, born at Sotés, Province of Logroño. He participated in the first Carlist War, during which he rendered heroic service, and while Captain General of Catalonia he helped to promote the revolution of 1854. In 1862-66 he was Captain General of Cuba, in which post he furthered all reforms, particularly such as led to the suppression of the slave traffic. He was reappointed in 1869, but soon after resigned.

DULCIGNO, dōol-chē'nyō. A fortified seaport of Montenegro, on the shore of the Adriatic, 15 miles south-southwest of Scutari (Map: Balkan Peninsula, B 4). It has a mediæval castle which was once an important stronghold. The harbor is difficult of access, but deep enough for heavy vessels. The inhabitants, numbering about 5000 in 1912, are engaged chiefly in oil trade and seafaring. Dulcigno belonged until 1180 A.D. to the Byzantine Empire and subsequently to the Serbs and Venetians, passing to Turkey in 1571. It was taken by the Montenegrins in 1878, but did not come permanently into their possession until 1881.

DUL/CIMER (OF. *doulcemer*, from Sp. *dulcé-mele*, It. *dolcemele*, dulcimer, from Lat. *dolce melos*, sweet song, from *dulcis*, sweet, and Gk. μέλος, *melos*, song). A very ancient musical instrument which has varied greatly in its form. In modern times its construction has resembled a flat box, with sounding board and bridges, strung with thin wire, and played on by striking the wires with mallets which have one soft and one hard face. Its compass is from *g* to *g'*. In England its tuning has been always diatonic, but in Germany towards 1800 it became chromatic. The dulcimer was the prototype of the

pianoforte just as the psaltery was of the harp-sichord, the sole difference between them being that the dulcimer was played with hammers and the psaltery with a plectrum. It was formerly

DULCIMER IN CASE.

supposed that the dulcimer was of German origin, but it is more likely that it came from the East through the Crusades; for it was known in Persia and Arabia for centuries under the name of *santir*. By 1550 it was known in Europe under its present name, but little importance was attached to it. The pantaleon (q.v.) was an enlarged form of a dulcimer. See PIANOFORTE.

DULCINE'A DEL TOBO'SO, *Sp. pron.* dōol'-thē-nā'a del tō-bō'sō. The romantic title given by Don Quixote to the peasant's daughter Aldoriza Lorenzo, who was born at Toboso, and whom he selects as his lady, and whose champion he becomes. The name Dulcinea is a popular term for a lady love.

DUL/CINISTS. The followers of Dolcino. See APOSTOLIC BRETHERN.

DULK, dulk, ALBERT FREDERICK BENNO (1819-84). A German author. He was born in Königsberg and studied medicine and the natural sciences in that city and in Leipzig and Breslau. He took an active part in the popular uprising of 1848, at which time his revolutionary drama *Lea*, closely related to Hauff's tale *Jud Süß*, appeared. Dulk was a very eccentric, although quite talented, man. His doctrines of free love, personally and more or less openly put into practice, did not help his influence. After traveling in the Orient he settled in Geneva in 1850, and subsequently in Stuttgart, where he wrote the dramas *Jesus der Christ* (1865) and *Simson* (1859), in which play the conflict between Judaism and paganism is depicted. One of his later dramas, *König Enzo*, was set to music by Abert. His earlier dramas are somewhat superficial and very realistic, his later ones, e.g., *Willa* (1875), approach more nearly the norm. As an adherent of socialism, he became conspicuous, in 1871, through his opposition to the war with France, and his publications *Patriotismus* and *Frömmigkeit* obtained a wide circulation. In 1822 he founded in Stuttgart the first society of freethinkers in Germany, and during the last years of his life devoted his pen principally to the discussion of the radical side of religious-philosophical subjects. *Der Irrgang des Lebens Jesu* (2 vols., 1884-85) showed his irreconcilable differences with Christian doctrines and views of life. His complete dramatic works were issued in 3 vols., 1893-94. Consult Ernst Ziel, *Albert Dulk, sein Leben und seine Werke* (1895).

DÜLKEN, dül'ken. A town in the Rhine Province, Prussia, Germany, 20 miles west of Düsseldorf. It is a thriving industrial town, with iron foundries and manufactures of ma-

chinery, silk, velvet, cotton, linen, dyestuffs, and cigars. Pop., 1900, 9517; 1910, 10,517.

DULLER, düöl'tër, EDUARD (1809-53). A German historian, theologian, and poet. He was born and educated in Vienna. Notwithstanding the success of his drama, *Meister Pilgram*, which was publicly performed before the author was 19, he left Austria and went to Germany in 1830, residing successively in Munich, Frankfurt, Darmstadt, and Mainz, where he was appointed preacher in the German Catholic church (1851). He took a prominent part in the German Catholic movement and was a strenuous defender of religious liberty. He contributed the libretto to Mangold's opera *Tannhauser*. Besides several meritorious lyrical and dramatic productions, he published the following standard historical works: *Vaterländische Geschichte* (5 vols., 1852-57; subsequently concluded by Hagen); *Geschichte des deutschen Volks* (7th ed., 1891); *Geschichte der Jesuiten* (1845; latest ed., 1893).

DULONG, dü'lôn', PIERRE LOUIS (1785-1838). A French physicist and chemist, known chiefly for the law which he discovered, jointly with Petit, in 1819. According to the law of Dulong and Petit, the specific heat of an element, multiplied by its atomic weight, is the same for all solid elements. The law was established empirically, and no theoretical explanation of it has yet been found. Dulong received his education at the Ecole Polytechnique, where he became, in 1820, professor of physics. In 1823 he was admitted into the Academy of Sciences. While working on the composition of the chloride of antimony he lost an eye through the explosion of a quantity of this substance.

DULONG AND PETIT, pe-tê', LAW OF. See ATOMIC WEIGHTS; DULONG.

DULSE (Gael. *duileasg*, dulse, from *duille*, leaf + *uisge*, water). *Rhodococcus palmata*. An edible seaweed, of the family Rhodophyta, which grows on rocky marine coasts. It is used as an article of food by poor people on the coasts of the British Isles and other northern countries, and occasionally also as a luxury by some of the wealthier classes who have acquired a taste for it. It has a purple, leathery or somewhat membranous, veinless, sessile leaf, irregularly cut, with deeply forked segments, which are either entire or edged or furnished with lateral leaflets. The spores are distributed in cloudlike spots over the whole leaf. The name "dulse" is also given in the southwest of England to another seaweed, *Iridaea edulis*, one of the Ceramiales, which has an undivided, obovate, or wedge-shaped, expanded, very succulent leaf of a dull purple color. It is occasionally employed as food both in the southwest of England and in Scotland. *Laurencia pinnatifida*, of the Rhodomelaceae, has a compressed, cartilaginous, twice or thrice pinnatifid leaf. It has a pungent taste and is used as a condiment when other seaweeds are eaten. In Alaska the name "dulse" is given to the seaweed *Porphyra laciniata*. It is gathered, pressed into cakes, and dried. When desired for use, it is broken or shaved into hot water and cooked for half an hour, when a nourishing porridge is obtained. Similar uses of this and related plants are reported from Japan, China, and elsewhere along the Pacific coasts.

DULUTH, dü-löth'. A city and lake port, the county seat of St. Louis Co., Minn., at the western end of Lake Superior, 152 miles

north-northeast of St. Paul, separated from Superior, Wis., only by the St. Louis River (Map: Minnesota, F 4). The city is especially favored with facilities for transportation by rail and water. It is the terminus of the Northern Pacific, the Chicago and Northwestern, the Great Northern, and on the Chicago, Milwaukee, and St. Paul, the Duluth and Iron Range, the Duluth, Missabe, and Northern, the Duluth South Shore and Atlantic, the Duluth, Winnipeg, and Pacific, and the Minneapolis, St. Paul, and Sault Ste. Marie railroads, and of several steamship lines. Duluth has a natural harbor, 9 miles long and 2 miles wide, entrance to which is made by two canals—the principal one being at Duluth, the other 7 miles south—both piercing the narrow strip of land, called Minnesota Point, which separates the lake from the harbor. The city's trade by water is greatly facilitated by the Sault Ste. Marie Canal (the traffic of which greatly exceeds that of the Suez Canal) and is considerably increased by the fact that this is the nearest shipping city on the lakes for the Northwest. Duluth now ranks among the leading shipping points in the United States, the total yearly traffic of the combined port of Duluth-Superior being in 1913 about 50,000,000 tons. Its exports amounted in 1913 to \$2,876,722, of which lumber, flour, iron ore, and grain are the most important; the imports were valued at \$1,278,452. It has a large steel plant, a blast furnace, iron works, cement factory, machine shops, match factories, saw mills, flour mills, and other industrial works. The city has abundant water power, containing a plant with a minimum of 55,000 electric horse power developed from the St. Louis River, under a fall of 378 feet. Duluth is the seat of Protestant Episcopal and Roman Catholic bishops. It has a Carnegie library of 60,000 volumes, State normal school, United States Fisheries building, United States customhouse, county work farm (for minor offenders), a hospital, and an aerial bridge, spanning the ship canal. There are 400 acres of parks and 20 miles of boulevards. Lester, Lincoln, Fairmount, and Chester parks, and Rogers Boulevard, a drive 500 feet above the lake, command beautiful views. Fond du Lac, a suburb at the head of navigation from Lake Superior, is one of the oldest towns in Minnesota, having been the site of the Astor trading post in 1752.

Duluth adopted the commission form of government in December, 1912, consisting of a mayor and four commissioners, elected at large for four-year terms. This body appoints all subordinate officers except judges of the municipal court, who are elected by popular vote. The city owns and operates its water works and gas plant. The annual income in 1912 was \$2,974,000; annual expenditure (including amounts for schools which are separately administered through a school district independent of the municipality), \$2,937,000; the principal items of expense were: education, \$469,000; fire department, \$180,000; water works, \$113,000; and police department, \$108,000. Duluth was first permanently settled in 1853, and takes its name from Daniel de Greyclon, Sieur du Luth, who in 1679-80 visited this vicinity. It was only ceded by the Indians in 1855, received its charter as a town two years later, and in 1870, with a population of about 3000, it was incorporated as a city. Since then

its growth has been very rapid, a population of 3483 in 1880 having increased to 52,969 in 1900 and to 78,466 in 1910. Of this number 30,652 persons were of foreign birth and 410 of negro descent. The estimated (U. S.) population in 1914 was 89,331.

DU LUTH, or **DU LHUT**, DANIEL GREYSON, SIEUR (1649-c.1709). A French explorer, born at Saint-Germain-en-Laye. He joined the royal guard, was commissioned a captain and sent to Canada, but returned to France in 1674 to take part in the campaign against William of Orange. When again in Montreal, he organized an expedition which, leaving Sept. 1, 1678, arrived at the head of Lake Superior July 10, 1679, having spent the winter at Lake Huron. Du Luth established friendly relations with the Sioux Indians, did much traveling during the summer, and in September held a council of the chiefs of warring tribes. In June, 1680, he went to Fond du Lac, crossed over to the Mississippi River, and obtained the release of Father Hennepin and his two companions who had been prisoners among the Sioux. In 1695 he commanded Fort Frontenac. The city of Duluth was named in honor of this man, who was one of the first to explore the region which later was known as the State of Minnesota.

DULWICH, dül'ich. A suburb of London, in Surrey, 4 miles south-southeast of St Paul's Cathedral and near Sydenham (Map: London, F 7). It is chiefly notable for its college and fine picture gallery. Dulwich College, or the College of God's Gift, was founded in 1619 by the actor, Edward Alleyn, who is buried in the chapel. The picture gallery was bequeathed to the college by Sir Peter F. Bourgeois and is now the property of the Dutch masters. Pop., 1911, 14,975.

DUMA (Russ., Council). The Lower House of the Russian Parliament. The first Duma, or general representative council, met in 1906. The suffrage qualifications were made quite low, and, according to the Czar's promise, responsible government was to be granted, and no law made effective without the Duma's consent. The old Council of the Empire was converted to an Upper House of Parliament, and the Duma was made the Lower in accordance with the usual constitutional practice of the Continent. Despite this arrangement, however, the government paid no attention to the demands of this Lower House, continuing vigorously the persecution of the Jews; and in the meanwhile anarchy prevailed in Russia, with serious revolts in Sebastopol and Moscow. The Duma criticized freely the actions of the government and the Czar's friends, whereupon it was promptly dissolved. The next year a new Duma assembled, but, as a majority of the former body were declared ineligible (by government fiat), it was more conservative in tone. The police, nevertheless, attempted to arrest several of its members. The Duma resisted and, like its predecessor, was dissolved for defiance of constitutional guarantees. Regulations were now changed. Poland lost two-thirds of her representatives, while the quotas from the great cities and the peasantry were also diminished. The third Duma, which met in 1907, largely composed as it was of priests, large land proprietors, and retired officials, proved itself almost, if not quite, subservient, and since that date the Russian Dumas,

their power largely emasculated, their membership strictly regulated, have been easily managed by the autocracy. See RUSSIA.

DUMAGUETE, dū'ma-ga'ta. The capital of the Province of Negros Oriental, on the island of Negros, Philippines (Map: Philippine Islands, H 10). It is situated in a flat region on the southeast coast of the island, 66 miles south-southeast of Bacolod. The chief industries are the gathering of turtle shells and cotton. Pop., 1903, 14,894.

DUMANGAS, dū-mang'as. A town of Panay, Philippines, in the Province of Iloilo, on the northeast of the reaches of the Jalour River, northeast of Iloilo (Map: Philippine Islands, D 5). It is situated in a fertile and well-watered region. The town was founded in 1572. Pop., 1903, 12,428.

DUMANJUG, dū'man-hōōg'. A town of Cebu, Philippines, situated on the coast at the mouth of the river of the same name, 35 miles southwest of Cebu (Map: Philippine Islands, D 6). Pop., 1903, 22,203.

DUMAS, dū'mā, ADOLPHE (1806-61). A French author and poet, born at Chartreuse de Bon Pas, Vauluse. He wrote: *Les Parisiennes* (1830); *La cité des hommes* (1835); *Le camp des croisés* (1838). His poems, *Un hameau de ravin* (1858), were written in the "langue d'oc."

DUMAS, ALEXANDRE, called **DUMAS PÈRE** (1802-70). The greatest French romantic novelist and the most universally read story-teller of the world, born at Villers-Cotterets, July 24, 1802. As a writer, he is remarkable for great creative rather than for artistic genius. Dumas was the grandson of the Marquis Alexandre Davy de la Pailleterie and a negress, both of Haiti; his father, Alexandre Davy de la Pailleterie Dumas, was for a time general under Napoleon. Dumas was a strange embodiment of the contrast and combination of the mental and physical characteristics of his grandparents. His awkward age and calf love are painted in his *Mémoires* and in *Ange-Pitou*. He came at first to law and was apprenticed to a notary of Soissons, where he saw, in 1819, a play of Ducis (q.v.) that determined him to seek his fortune on the stage. He reached Paris in 1823, with 20 francs and hope for all his patrimony. He found a temporary livelihood as secretary in the household of the future king, Louis Philippe, and in 1829 was among the first to begin the romantic revolt on the stage in his *Henri III et sa cour*, the first real triumph of the Romanticist school. Actively engaged in the revolution of 1830, he proved a too ebullient Republican to find favor in the royal household and resigned his post. He now produced the first of his historical novels, *Isabelle de Bavière*, out of which there grew in his fertile brain a scheme for turning the whole history of France into a sort of human comedy that should "exalt history to the height of fiction" and let a romantic fancy play around the evidences of the past. The *Chroniques de France* that resulted from this idea are Dumas's best work. They exhibit, indeed, no historic insight and no grasp of character; but they show a wonderful dramatic instinct to fuse and recast historic materials into chaplets of episodes that are by turns frolicsome and wild, extravagant, breathless, and impetuous, subordinating description to dialogue and everything to action, never failing to absorb the reader and to excite an intense curiosity. In

their historical order these chronicles are: *Le bâtard de Mauléon*; *Duguesclin*; *Isabelle de Bavière*; *La reine Margot*; *La dame de Montsoreau*; *Les quarante-cinq*; *Les trois mousquetaires* (the best); *Vingt ans après*; *Le vicomte de Bragelonne*; *La chevalier d'Hermantail*; *Une fille du régent*; *Joseph Balsamo*; *Le collier de la reine*; *Ange-Pitou*; *La comtesse de Charny*; *Le chevalier de Maison-Rouge*; *Les blancs et les bleus*; *Les compagnons de Jésus*; and *La rose rouge*—the whole forming a series of well-nigh 100 volumes, which have served as models for the present-day cheaper novels of adventure and wild passion.

Dumas took his material where he found it, having barbaric ideas of literary propriety. Already in 1832 a well-founded charge of plagiarism had forced him to travels, of which he has left a lively series of *Impressions*. (Consult Wormeley, *Journeys with Dumas*, Boston, 1902.) It did not lead him to mend his ways, however. Volumes have been written about his "novel factory," of his purchase of work by unknown authors or translators, and of publishing under his name what he had not so much as read (consult Quérard's *Les supercheries littéraires*, 1859); though these charges have been grossly exaggerated. He was always ready to buy ideas, he was willing to buy novels and rewrite them, he also supplied ideas and let others do the mechanical work of composition, and in later life he may have been even less scrupulous; but none who claimed to share his honor as well as his profits ever did under their own names work like that which they claim to have done for him, and we know that Dumas was as rapid and industrious a penman as he was a facile composer. No doubt he squandered his genius under the urgent demands of the press. Nor did he confine himself to novel writing; he was a most forceful figure in the Romantic drama. His *Antony* (1831) introduced the modern social play and popularized the pale-faced, dark-haired, wicked Byronic hero in France. His melodramatic *Tour de Nesle* (1832) reeked with mystery and crime.

Although his best work was almost all done between 1843 and 1850, in one way or another Dumas is responsible for 298 somewhat closely printed volumes. For a generation he was the world's Scheherazade, doing more than all others together to give French fiction a cosmopolitan audience in the great middle class, while he also found admirers among the highly cultured, such as Thackeray. His work brought enormous returns, but he was a phenomenon of thriftlessness. He became involved in many lawsuits over contracts signed with thoughtless levity. He built a palace, Monte Cristo, for 500,000 francs in 1847, then sold it in 1851, and fled from his creditors in 1853. Then for 19 years he became a pathetic wanderer in search of "copy." He visited England (1857), Russia and the Caucasus (1858), and Italy (1860 and 1866). Last came four years of sterile poverty, relieved by the son whose boyhood he had neglected and whose youth he had misguided. By him he was taken from the excitements and dangers of Paris in war time to Puy, near Bordeaux, where he died on the day of its occupation by the Prussians. Dec. 5, 1870. He was buried in 1872 at his boyhood's home in Villers-Cotterets. A uniform and nearly complete translation of Dumas's novels is published in Boston. Consult: Blaze de Bury, *Alexandre*

Dumas, sa vie, son temps, son œuvre (Paris, 1885); Wells, *A Century of French Fiction* (New York, 1898); Parigot, *Le drame d'Alexandre Dumas* (Paris, 1898); id., *Alexandre Dumas père* (ib., 1902); A. B. Davidson, *Alexandre Dumas père, his Life and Works, with Bibliography* (New York, 1902); A. Maurel, *Les trois Dumas* (*Le général, A. Dumas père, et fils*) (Paris, 1896).

DUMAS, ALEXANDRE, called **DUMAS FILS** (1824-95). One of the most distinguished of modern French dramatists. He was born in Paris, July 27, 1824, the son of the great romantic novelist of like name, but of a genius strangely contrasted. In him the father's rich but riotous fancy yielded to close observation and realistic earnestness that made of him an unbending and almost a Puritan moralist. Like his father, an illegitimate child, he was drawn, in *L'Affaire Clémenceau* (novel, 1867; dramatized, 1887), a moving picture of the torments caused by his origin during his school life. Later he became the companion and associate of his bohemian father and after a brief carnival found himself, in 1848, with 50,000 francs of debt and a pen for his assets. He left old associations forever behind, sold his experience to the world in a novel, *La dame aux camélias* (1848; dramatized, 1852), and became a serious, hard-working author and soon an independent and wealthy one. His other early novels and a first dramatic essay (1845) are romantic commonplace and have no significance. But the dramatization of *La dame aux camélias* marks a date (Feb. 2, 1852) in the history of the French stage and inaugurates the realistic study of social problems that has changed the face of the modern drama. Dumas joined Balzac's insight into character to Scribe's technical attitude and to an instinct that truth, to be dramatically effective, must be logical and conventional in its exhibition. In so far Dumas is not a naturalist, though he is eminently a dramatic realist. He was the sponsor for the "comedy of manners" which was widely imitated by the dramatists of his period, especially in Germany. His other plays, in their order, are: *Diane de Lys* (1853); *Le demi-monde* (1855); *La question d'argent* (1857); *Le fils naturel* (1858); *Un père prodigue* (1859); *L'Ami des femmes* (1864); *Les idées de Madame Aubray* (1867); *Une visite de noces* (1871); *La princesse Georges* (1871); *La femme de Claude* (1873); *Monsieur Alphonse* (1873); *L'Etrangère* (1876); *La princesse de Bagdad* (1881); *Denise* (1885); *Francillon* (1887). Their perennial theme is the baneful influence of romantic love, false sentiment, and chivalrous passion. *La dame aux camélias* had shown him disposed to an open-armed charity towards ladies of easy virtue who aspired to a virginity of the heart after the manner of Prévost's Nanon Lescaut and Hugo's Marion de Lorme and Fantine (*Les misérables*). But *Diane* shows sterner stuff, and all the dramas that follow are social sermons, each provided with a frank and forceful preface to enforce its lesson of warning against the women of that type.

In general the dramas are rather gloomy pictures of relations that, as one of his heroines remarks, "began because I was bored and ended because he bored me." They are very witty, but the wit is not kindly, and often it is too didactic. The style is a marvel of conciseness and clearness, "all muscles, nerves, and action"; the language was at first incorrect, and to the

last full of new-coined phrases; the characters are apt to be abstractions, types repeated over and over. Clémenceau's wife, Iza, e.g., is the Countess of Terremonde in *La princesse Georges*, and the Valentine of *Le demi-monde* and the incarnate Beast of *La femme de Claude*. His *Les idées de Madame Aubray* marks him as a pioneer in the field of problem plays. But, after all reserves have been made, the son of the author of *Monte Cristo* was the most purposeful, forceful, and serious of the French dramatists of the nineteenth century. He died at Marly-le-Roi, Nov. 27, 1895.

Dumas's dramas are collected in seven volumes (1890-93), with two volumes of plays revised and adapted by him, *Le théâtre des autres*. Four volumes of essays, chiefly on social subjects, appear as *Entr'actes* (1878-90). Consult: Zola, *Nos auteurs dramatiques* (Paris, 1881); Bourget, *Essais de psychologie contemporaine* (ib., 1883); Doumic, *Portraits d'écrivains* (ib., 1892); Matthews, *French Dramatists* (New York, 1901); H. d'Alméras, *Avant la gloire* (Poitiers, 1902); C. M. Noel, *Les idées sociales dans le théâtre de A. Dumas fils* (Paris, 1912).

DUMAS, GUILLAUME MATTHIEU, COUNT (1753-1837). A French general, politician, and military historian, born at Montpellier, Nov. 23, 1753. After receiving a military education, he became in 1776 a lieutenant in the army, and in 1780 accompanied the Comte de Rochambeau to America as aid-de-camp and took part in the principal actions of the war, including the siege of Yorktown. He returned to France with the rank of major. After executing a military investigation in the Levant, and a mission of observation in connection with the Dutch revolution of 1787, he was raised to a colonelcy. He was lieutenant in the camp in 1789 and sided with the Girondins and the Liberal party. In 1791 he was elected to the Constituent Assembly and the next year was chosen President of that body. During the Reign of Terror he absented himself from France, with some brief intervals. In 1797 he was proscribed as a monarchist and fled to Holstein. When Bonaparte became First Consul, Dumas was recalled and appointed chief of staff to the army of Dijon. He was subsequently Councilor of State, grand officer of the Legion of Honor, and general of division. In this last capacity he was present at the capitulation of Ulm and the battle of Austerlitz (q.v.), in the latter of which he distinguished himself by high courage and dashing tactics. In 1806 he went with Joseph Bonaparte to Naples and was made Minister of War. In 1808 he served in the French army in Spain and after the battle of Wagram he was employed in negotiating an armistice with Austria. In 1810 he was made a count of the Empire. In the Russian campaign of 1812 Dumas filled the arduous post of intendant general, and after the retreat he fought at Lützen and Bautzen. Subsequent to the defeat at Leipzig he was intrusted with the task of arranging for the capitulation of Dresden; but his conditions were not accepted by the Allied Powers, and he was arrested and imprisoned until the conclusion of peace in 1814. He was in favor under the first Bourbon Restoration and held important commissions. Upon Napoleon's return from Elba Dumas was persuaded to take charge of the organization of the National Guard. When Louis XVIII returned, Dumas was obliged to retire on half pay. In 1818 he was restored to favor and made, for a

short time, a member of the Council of State, and in 1828 was a deputy in the Chamber from Paris. After the events of 1830, in which he took a prominent part, he was made a peer, re-entered the Council of State, and became president of the War Committee. He died Oct. 16, 1837. Besides an important military history, *Précis des événements militaires, 1798-1807* (19 vols., Paris, 1817-26), Dumas left an autobiographical work, *Souvenirs du lieutenant-général comte Matthieu Dumas, 1770 à 1836* (Paris, 1839; Eng. trans., Philadelphia, 1839-40).

DUMAS, JEAN BAPTISTE (1800-84). A distinguished French chemist, born at Alais, in the Department of Gard. He was at first apprenticed to an apothecary in Geneva and engaged in some scientific work that attracted the attention of Berzelius and Prévost. In 1823 he went to Paris and was appointed chemical répétiteur (tutor) in the Ecole Polytechnique, and then professor of chemistry in the Athenæum. He was afterward transferred to the Sorbonne and made a member of the Academy of Sciences. His researches on atomic weights, sulphuric ether, and the phenomena of substitution in organic chemistry attracted attention over all Europe. In 1830, July monarchy he was a member of the Council of Education. After the revolution of February he was chosen a member of the Legislative Assembly, and from 1849 to 1851 he held the portfolio of Agriculture and Commerce. After the coup d'état he was made a member of the Senate and of the Superior Council of Public Instruction. Numerous contributions from his pen are contained in the *Annales de l'Industrie* and other scientific journals, including the *Mémoires de l'Académie*. His chief works are: *Traité de chimie appliquée aux arts* (8 vols., 1828-45); *Leçons sur la philosophie chimique* (1837); *Essai sur la chimie des êtres organisés* (1841; 3d ed., 1844); etc. Dumas delivered the first Faraday lecture before the London Chemical Society, in 1869. Consult Hofmann, *Zur Erinnerung an Jean Baptiste Dumas* (Berlin, 1885). See **CHEMISTRY, History**.

DU MAURIER, du mō'ryā', **GEORGE LOUIS PALMELLA BUSSON** (1834-96). An English illustrator and novelist, born in Paris. On his father's side he was of French descent; his mother was English. His boyhood was passed in London, Boulogne, and Paris, and at the age of 17 he took up the study of chemistry in University College, London. On the death of his father (1856) Du Maurier adopted art as his profession, studying in Paris under Gleyre and in Antwerp under De Kaiser and Van Lerius. In 1859, while drawing in the studio, he suddenly lost the sight of one eye, and during the rest of his life worked under the menace of total blindness. Returning to London, he began drawing for *Once a Week*, *Punch*, and the *Cornhill Magazine*, and on the death of Leech (1864) he became permanently attached to *Punch*, to whose pages he contributed those examples of social satiric art now so well known. For his drawings he himself composed the clever legends. He also illustrated Thackeray's *Henry Esmond* and *Ballads*, and works by Henry James, Thomas Hardy, George Meredith, Mrs. Gaskell, and others. To *Harper's Magazine* he contributed a series of drawings and two novels—*Peter Ibbetson* (1891) and *Trilby* (1894). The former, a fanciful romance of dream life, was widely read—chiefly, it would appear, through interest

in the autobiographic record of the author's life at Passy. The latter, whose scene is the Quartier Latin, met with phenomenal success and was dramatized in both England and America. Whatever may be thought of the melodramatic presence of Svengali, the study of the artist trio, occupying the earlier portion of the story, is generally regarded as a genuine achievement. Subsequently to Du Maurier's death a third novel, *The Martian*, appeared in *Harper's* (1896-97). He was also a skillful writer of light verse, specimens of which appeared in *Punch* and dispersed through his books. But his reputation will chiefly rest upon that illustrative work for *Punch* through which he smilingly assailed the snobbish and the mean in the fashionable and artistic world, and which, by its copiousness of detail, forms a valuable historical storehouse for the future student of English manners and customs of his period. His drawings possess much grace, charm, and finish, and his peculiar type of woman became known everywhere.

DUMB. See DEAF-MUTE.

DUMB AGUE. A common name of a form of intermittent fever in which there is a cold sensation in place of the shaking chill, and the succeeding fever is present; or of chronic malarial infection in which there is no regular chill, fever, and sweat, but all other conditions are present. See INTERMITTENT FEVER.

DUMBARTON, dūm-bār't'n, or DUNBARTON (Gael. *Dumbreaton*, fort of the Britons; called by the Britons *Alcluth*, height on the Clyde). A royal, parliamentary, and municipal port, and capital of the County of Dumbarton, Scotland, on the Leven, near its junction with the Clyde, 15 miles west-northwest of Glasgow (Map: Scotland, D 4). It consists chiefly of a long semicircular street parallel to the river. Its principal public buildings are the Dumbarton Academy and county building. Shipbuilding, marine-engine and machine making, iron forging, iron and brass founding, and rope making are the chief industries. It has regular steam communication with Glasgow, Greenock, and other Clyde ports. Pop. (municipal burgh), 1901, 19,985; 1911, 21,989. Dumbarton was called *Alcluth* (hill of the Clyde) by the Britons, and *Dunbreatan* (fort of the Britons) by the Celts, and was the capital of the British district of Strathclyde. The Romans had here a naval depot, called *Theodosia*. Alexander II in 1221 made it a royal burgh. At the mouth of the Leven stands the castle of Dumbarton, on a steep, rugged, double-peaked basaltic rock, rising to the height of 240 feet. It is one of the four Scottish castles which by the terms of the treaty of union between England and Scotland, must be maintained. Its armament now consists of a few obsolete cannon. It was for a time the prison of the Scottish hero Sir William Wallace and served as a residence for Mary, Queen of Scots, during her childhood, and prior to her departure for France. Consult Irving, *Dumbarton* (Dumbarton, 1865).

DUMBARTONSHIRE. A county in the west midland division of Scotland (Map: Scotland, D 3). Area, 267 square miles. The northern and western portions are mountainous, with many peaks from 2000 to 3000 feet high, and numerous lovely lakes—the largest, Loch Lomond. Here the scenery is indescribably beautiful. Well-cultivated lands lie south of Loch Lomond and along the Clyde east and

west of Dumbarton Castle. Turkey-red dyeing, bleaching and printing of calicoes, engine and ship building, distilling and brewing, and coal and ironstone mining are the chief industries. Pop., 1801, 20,700; 1851, 45,100; 1901, 113,865; 1911, 139,831. Capital, Dumbarton (q.v.). Consult Irving, *Dumbartonshire* (Dumbarton, 1860).

DUMB-BELL (so called from a fancied resemblance of the balls to bells). A weight used in calisthenic and other physical exercises. It consists of two balls of iron, or, for light exercise, of wood, connected by a bar for a handle. The present form of dumb-bell was in use in England as early as the reign of Queen Elizabeth; and weights, called *halteres*, that were similar to modern dumb-bells, were used by the quoit players in the early Grecian games. See GYMNASTICS.

DUMDUM (*damdama*, raised mound or battery). A town and military cantonment in the District of Twenty-Four Parganas, Bengal, British India, 10 miles southeast of Barrackpur and 5 miles northeast of Calcutta (Map: India, E 7). It has extensive accommodations for troops and a government ammunition factory. Here are manufactured the famous dumdummy soft-nosed bullets, which flatten when they strike, tearing a large wound. The place is famous in connection with the mutiny of 1857. It was the scene of the first open manifestation on the part of the Sepoys against the greased cartridge. The manufacture of jute began about 1901, 20,830.

DUMDUM BULLET. A bullet sometimes used in the British army, where it is styled "Mark IV." It resembles the ordinary service bullet, except that the leaden core is left uncovered, and, by further making the casing weak at the apex, the bullet spreads out immediately on striking a bone and tears or splinters the body, usually with fatal results. It was first made at the Dumdummy Arsenal in India. *Dumdummy*, or *Damdama*, is the name of a town, in Bengal Presidency, noted for its arsenal and for the fact that the mutiny of 1857 originated there. The reports of the British officers in the Chitral campaign of 1895 called attention to the fact that, while the service small-bore bullet had immense penetrative power, it did not possess sufficient stopping power; and a man struck by it did not at once suffer shock or disablement, but continued to fight. The wound of the Lee-Metford (the British service rifle) bullet, like that of the Mauser, is a perfectly clean perforation, which in many instances will soon heal. It was to secure greater stopping power that the dumdummy was employed. It is under the ban of the Peace Conference; Great Britain employed it, but only against uncivilized peoples, until the Second Peace Conference at The Hague, 1907. She then acceded to the declaration, so that the United States is now the only country outside the operation of the dumdummy bullet, however, is not used in the United States army. It was used in Egypt in 1895, but not in the Boer-British War of 1899-1902.

DUMÉRIL, du'mā'rēl', ANDRÉ MARIE CONSTANT (1774-1860). A French physician and naturalist, born at Amiens. In 1801 he was appointed professor of anatomy and physiology at the University of Paris, where in 1819 he also obtained the chair of internal pathology, which he occupied for more than 40 years. He was also at one time the substitute of Cuvier

in the department of natural history of the Ecole Centrale du Panthéon. It was, however, as assistant of Lacépède, in the course of herpetology and ichthyology, at the Jardin des Plantes, that he obtained that wide experience and extensive information which enabled him to write the first comprehensive work on reptiles, entitled *Erpétologie générale, ou histoire naturelle complète des reptiles*, in collaboration with Bibron (1834-54). His other publications include: *Traité élémentaire d'histoire naturelle* (1804; 2d ed., 1807); *Zoologie analytique* (1806); *L'Ichthyologie analytique* (1856).

DUMÉRIL, AUGUSTE HENRI ANDRÉ (1812-70). A French naturalist, son of André M. C. Duméril. He was born in Paris and studied medicine at the university in that city. In 1847 he was appointed professor of geology at the Collège Chaptal, and 10 years later he succeeded his father as director of the Museum of Natural History. He assisted in the preparation of his father's *Erpétologie* and wrote *Des odeurs* (1843); *De la texture intime des glandes* (1845); *Histoire naturelle des poissons* (1865-70).

DUMÉRIL, EDELESTAND PONTAS (1801-71). A French philologist. He was born at Valognes, Normandy, and subsequently removed to Paris. After the death of Garin le Loharam and the discovery of mediæval French text, he began the collection of mediæval Latin poetry, published under the respective titles *Poésies latines antérieures au XII^{ème} siècle* (1843) and *Poésies latines du moyen âge* (1847). These works won for him a wide reputation as a Latinist. As a literary critic and historian of literature, he wrote *Sur l'origine des runes* (1844); *Origines latines du théâtre moderne* (1849); *Des formes du mariage pendant le moyen âge* (1861); *Histoire de la comédie* (1864-67).

DUMERSAN, du'mâr'sân', THÉOPHILE MARION (1780-1849). A French numismatist and playwright, born in the castle of Castelnaud, near Issoudun, Indre. In 1842 he was appointed director of the royal cabinet of coins, after an association of nearly 50 years with that establishment. He wrote about 230 vaudevilles, among which *L'Ange et le diable*, a drama in five acts, was very popular. His best work, however, and one which is still referred to as a model of its kind, is the play entitled *Les saltimbanques* (1838). His principal work on numismatics is the *Notice des médailles exposées dans le cabinet des médailles et antiques* (1829; frequent subsequent editions).

DUMESNIL, du'mâ'nêl', MARIE FRANÇOISE (1713-1803). A celebrated French tragic actress whose real name was Marchand. According to the usual account, she was born in Paris, but her first experience upon the stage was gained in the provinces, at Strasburg and elsewhere. She made her début in the Théâtre Français in 1737 as Clytemnestra in *Iphigénie*. Her commanding appearance and power of tragic expression gave her immense control over her audiences. Once, it is related, those in the front seats were so overcome with horror that they fairly retreated before her, leaving their places vacant. Her superiority to her rival, Mademoiselle Clairon, is generally acknowledged, though there were critics who resented the innovations of her forceful genius. Among her great parts were *Athalie*, *Phèdre*, *Médée*, *Sémiramis*, and especially *Mérope*, which won for her both the admiration

and the gratitude of Voltaire, its author. She continued upon the stage till 1776, when she retired upon a pension largely supplemented by the favor of the court. She died at Boulogne-sur-Mer. Consult Coste d'Arnobat, *Mémoire de Marie Françoise Dumesnil* (Paris, 1800), written in reply to an attack upon her by Mademoiselle Clairon.

DUMFRIES, düm-frēs'. A royal parliamentary and municipal burgh, river port, and the capital of Dumfriesshire, Scotland, on the Nith, 9 miles from its mouth in the Solway Firth, 73 miles south-southwest of Edinburgh, and 33 miles west-northwest of Carlisle (Map: Scotland, E 4). It stands on rising ground, surrounded, except towards the sea, by fine, undulating hills, and is irregularly built of red freestone. One of the bridges across the Nith is believed to have been built about 1280 by Devorgilla, the mother of John Balliol, who also erected the Greyfriars' monastery in the chapel of which, in 1306, Robert the Bruce slew the Red Comyn. The burgh is associated with incidents in the life of James Burns, who was buried in St. Michael's churchyard. The houses in which he lived and the one in which he died are marked with tablets. Among the modern buildings may be mentioned the county building, a Scottish baronial structure, the post office, Crichton Institution, and the general infirmary. The municipality owns the water works, gas works, and public baths and workhouses. The chief industry is the manufacture of tweeds, hosiery, leather, baskets, and wooden shoes. Its cattle fairs are also of importance, and an import trade is carried on in oilseed cake, beans, and manures. Two objects of interest in the neighborhood are the ruins of Lincluden Abbey and Caerlaverock Castle, an ancient stronghold of the Maxwells, and the Ellangowan in *Guy Mannering*. Dumfries is believed to have grown up about an ancient British fortress. It was made a royal burgh by William the Lion. It suffered severely in the Border wars. In 1745 it was the scene of the Young Pretender, who raised the town's funds. Pop. (royal burgh), 1801, 10,511; 1811, 16,011. Consult Maxwell, *History of Dumfries* (Edinburgh, 1896).

DUMFRIESSHIRE. A border county in the southern division of Scotland (Map: Scotland, E 4). It has 21 miles of coast line on the Solway Firth, towards which its surface slopes from the northern portion, which is mountainous. The principal rivers are the Nith, Annan, and Esk, the valleys of which form the "dales" of the corresponding names. Area, 1072 square miles. The mineral products are coal, limestone, ironstone, lead, and silver. There are extensive lead mines at Wanlockhead; limestone is quarried in the parishes of Keir and Carmertrees; zinc ore is mined at Abington, and coal at Sanguhar and Canonbie. The chief occupations are agriculture and the raising of cattle, sheep, and swine. Sheep farms occupy the hills. There are salmon fisheries in the rivers. Pop., 1801, 54,600; 1851, 78,100; 1891, 74,245; 1901, 72,570; 1911, 72,825. Capital, Dumfries (q.v.).

DUMICHEN, du'mik-en, JOHANNES (1833-94). A German Egyptologist, a pupil of Lepsius and Brugsch. His numerous works consist almost entirely of editions of Egyptian inscriptions, derived from temples of the Greek and Roman period. He devoted special attention to the very complicated and difficult hieroglyphic

writing which prevailed during this period. In 1872 he was appointed professor of Egyptology at Strassburg. Among his works may be mentioned: *Griechische Inschriften altägyptischer Denkmäler* (1860); *Altägyptische Kalenderinschriften* (1866); *Historische Inschriften altägyptischer Denkmäler* (1867-68); *Der Felsentempel von Abu Simbel* (1869); *Der Grabpalast des Patumenap in der thebanischen Nekropolis* (1884-94).

DUMMER, JEREMIAH (1680-1739). An American clergyman, who spent the latter part of his life as a politician and lawyer in England. He was born in Boston, the brother of William Dummer, acting Governor of Massachusetts from 1723 to 1728, graduated at Harvard in 1699, and took his doctor's degree at Utrecht in 1703. After preaching for a time in Boston he moved to England, where he left the ministry, practiced law, and became a political lieutenant of Bolingbroke. He rendered valuable services to the Colony of Massachusetts, for which he was the London agent from 1709 to 1721. He is best known as the author of an able *Defense of the New England Charters* (1728), written at a time when Parliament seemed about to annul several of the Colonial charters. He also published *A Discourse on the Holiness of the Sabbath Day* (1704) and *A Letter to a Noble Lord Concerning the Late Expeditions to Canada* (1709). Consult a brief sketch in Tyler, *A History of American Literature to 1765* (New York, 1876).

DUMMER'S WAR (so called from William Dummer, acting Governor of Massachusetts from 1723 to 1728). A war (1723-25), occasioned in a dispute over boundary lines, between the Abnaki Indians and the border settlers of Vermont and Maine, then under the jurisdiction of Massachusetts. It was marked by numerous petty skirmishes and by two considerable engagements—one on Aug. 12, 1724, when a company of 208 whites massacred the Jesuit missionary Rale and some 26 Indians, and another on May 8, 1725, when 34 whites under Capt. John Lovewell defeated a much larger body of Indians, after a bloody contest on the site of the present Fryeburg, Me. Peace was concluded in November, 1725. For a brief account of the war, consult Parkman, *A Century of Conflict* (Boston, 1892).

DÜMLER, dum'lër, ERNST LUDWIG (1830-1902). A German historian. He was born in Berlin and was educated at the universities of Bonn and Berlin. In 1858 he became professor of history at Halle. In 1876 he became president of the Historical Commission for the Province of Saxony, and in 1888 he was chairman of the editorial board of the *Monumenta Germanica Historica* in Berlin. His publications include: *Geschichte des ostfränkischen Reiches* (3 vols., 2d ed., 1887), for which two prizes were awarded him by German academies; *Kaiser Otto der Grosse* (1876); *Auxilium und Vulgarius: Quellen und Forschungen des Papsttums im Anfang des zehnten Jahrhunderts* (1866); and numerous important contributions to the *Monumenta Germanica Historica* and similar publications.

DUMONCEAU, du'môn'sô', JEAN BAPTISTE, COUNT BERGENDAEL (1760-1821). A French soldier, born in Brussels. He was colonel of a regiment during the revolt of Brabant against Napoleon. In 1801 he suppressed the rebellion he fled to France and afterward fought at Jemappes and Wagram. In consequence of the bravery and skill displayed by him in these

important battles he was successively promoted to the rank of brigadier general (1793), commandant of Amsterdam (1794), and lieutenant general of the Batavian Republic (1795). In 1807 he became marshal of Holland, in which capacity he successfully conducted the operations against the English in Walcheren (1809). After the union of Holland with France he again distinguished himself in the campaigns of 1813-15, and Napoleon made him a count. The title of "the Stainless General" was bestowed upon him by reason of his unsullied record as a soldier.

DU MOND', FRANK VINCENT (1865-). An American figure and landscape painter. He was born in Rochester, N. Y., and studied in Paris under P. Lefebvre, and Benjamin Constant. His work, which includes religious pictures, landscapes, groups of young girls, and ideal paintings, has a distinctive quality; for he possesses the art of crowding much detail into harmonious masses. His color is delicate, his line sure. Among his most important paintings are: "The Baptism," "Portia," "An Italian Street," "July Afternoon" (1910); "October" (1911), and "The Margaree" and "Grassy Hill" (1913). He designed important illustrations for the *Century Magazine*, became influential as an instructor at the Art Students' League, New York, and was elected to the National Academy of Design in 1906.

DUMONT. See SANTOS-DUMONT.

DUMONT, du'môn', ALBERT (1842-84). A French archaeologist. He was born at Scey-sur-Saône, and was educated in Paris and at Athens. After lecturing on archaeology and the history of art in Rome (1874) and at Athens, as director of the French School of Classical Studies there (1875-78), he became rector of the academies at Grenoble (1878) and Montpellier (1879), and occupied the position of superintendent of higher education until his death. His researches covered a wide field, embracing prehistoric as well as Christian and Byzantine archaeology, while his treatment of the ceramic art of Greece reveals the profound scholar and keen, critical artist. Among his numerous important works are the following: *De Plumbis apud Græcos Tesseris* (1870); *Inscriptions céramiques de Grèce* (1871); *Vases peints de la Grèce propre* (1873); *Les céramiques de la Grèce* (1873); *Vases peints et terres cuites*, in *Revue archéologique* (1882-90).

DUMONT, AUGUSTIN ALEXANDRE (1801-84). A French sculptor. He was born in Paris. He studied with his father, Pierre Dumont (1761-1844), and with the sculptor Jean-Baptiste Carpeaux. In 1823 he won the Prix de Rome, afterward spending some years in Italy. The works of Dumont are very numerous; they were mostly executed for the public buildings and churches of Paris, and are to be found in the Senate, the Hôtel de Ville, at Versailles, and in the churches of the Madeleine and Notre Dame de Lorette. His two best-known works are "The Genius of Liberty," a colossal statue in gilded bronze on the July Column (1840), and the colossal bronze statue of Napoleon I on the Vendôme Column, seriously damaged during the Commune, but since restored. Other important statues are those of Nicholas Poussin for the Palace of the Institute; Blanche de Castille in the Luxembourg Gardens; and St. Cecilia in the Madeleine; he is especially well represented in the Museum of Sculpture. He was elected to the Institute in 1838.

professor at the Ecole des Beaux-Arts in 1852, and received the grand medal of honor at the Exposition of 1855. The boldness and finish, combined with grace, that distinguish the works of this sculptor show the influence of Canova. Consult Vattier, *Une famille des artistes: Les Dumont* (Paris, 1890).

DUMONT, PIERRE ETIENNE LOUIS (1759-1829). A Swiss philosopher, the leading disciple of Bentham, and the great expositor of the Benthamite philosophy. He was born in Geneva, July 18, 1759, studied theology, and after officiating as a minister for a short time in his native town, proceeded to St. Petersburg in 1783, where he accepted the charge of the French Protestant church. In 1785 he left Russia, went to England, and became tutor to the sons of Lord Shelburne, afterward Marquis of Lansdowne. His superior talents, liberal sentiments, and fine character soon recommended him to the highest of that period; with Sir S. J. P. in particular, he formed a close friendship. During the early years of the French Revolution Dumont was in Paris, where he became greatly attached to Mirabeau, regarding whom he has given the world much important information in his *Souvenirs sur Mirabeau et sur les deux premières assemblées législatives* (which were not published till 1832, three years after the author's death). In 1791 Dumont returned to England and formed an intimacy with Bentham. This led to the most important event in his life. Deeply convinced of the value of that philosopher's views on legislation, he requested his friend to allow him to arrange and edit his unpublished writings on this subject. Bentham gave him his manuscripts. Dumont labored earnestly and successfully to bring order out of the chaos of Bentham's writings and gave them a literary form and a currency which contributed powerfully to their influence. In the following works he appears as the interpreter as well as the editor of the philosopher: *Traité de législation civile et pénale* (Geneva, 1822); *Théorie des peines et des récompenses* (ib., 1810); *Tactique des législateurs* (ib., 1815); *Preuves judiciaires* (ib., 1823); and the *Organisation judiciaire et codification* (1828). Dumont returned to Geneva in 1814 and became a member of the Representative Council. He died in 1829 in Milan. Consult Vattier, *Review of Dumont's "Recollections of Bentham"* (London, 1832), and De Candolle, *Notice sur la vie et les écrits de M. Dumont* (Paris, 1829).

DUMONT D'URVILLE, JULES SÉBASTIEN CÉSAR (1790-1842). A French navigator, the discoverer of a portion of the so-called Antarctic continent. In 1820, while on a surveying trip in the *Venus*, he recognized the artistic value of a statue which had just been unearthed, and which is now known as the "Venus of Milo," and announced the discovery to the French government. In later years he was concerned in explorations around the Australian continent, New Zealand, Van Diemen's Land, and other Pacific and Indian islands for the purpose of finding traces of Lapérouse. In 1836 he submitted to Louis Philippe the plan of a new expedition which was to explore the Antarctic regions. Joinville Island and Louis Philippe Land were both discovered by him in 1838. After an extended cruise in the Pacific Ocean Dumont d'Urville returned to the far south, and on the afternoon

of Jan. 19, 1840, discovered a coast line in about lat. 65° S., long. 14° E. This he called Adélie Land. Clarie Land, a wall of ice, supposed by the Frenchmen to be attached to a land mass, was discovered on January 30. These two coasts were named by geographers to form part of the continent of a great land, called for convenience Antarctica, or the Antarctic continent. Lieutenant Wilkes, of the United States exploring expedition, had sighted another portion of the same coast farther to the eastward early in the morning of January 19. D'Urville was appointed rear admiral on his return. Eighteen months afterward he was killed in a railroad accident. Among his publications are: *Rapport sur le voyage de "L'astrolabe" lu à l'Académie des sciences dans sa séance du 11 mai, 1829* (1829); *Voyage pittoresque autour du monde* (1834); *Voyages au pôle sud et dans l'Océanie* (1841-54).

DUMORTIERITE, dü-môr'ti-ër-î-t. A basic aluminium silicate that crystallizes in the orthorhombic system, has a vitreous lustre, and is of a bright blue to greenish-blue color. It occurs in fibrous forms in feldspar near Lyons, France, and also in Silesia and in Norway, while in the United States it is reported from the vicinity of New York City, from California, and from Yuma Co., Ariz. It is named after Eugène Dumortier, the French paleontologist.

DUMOULIN, dū'mōō'lān', CHARLES (1500-66). A French jurist, born in Paris. He was a member of the Reformed Church and became celebrated as a consulting lawyer. He published in 1552 his *Commentaire sur l'édit des petites dates*, a famous argument to show the justice of the action of Henry II of France in forbidding the exportation of gold and silver from the kingdom to Rome. This work was promptly condemned by the Sorbonne and won him the honor of a heresy trial. Soon after his return from Germany in 1557 he published the *Conseil sur la fin de concile de Trent*, which greatly offended both Catholics and Calvinists, and for which he was imprisoned until 1564. His writings, comprising 50 other titles, were published in Paris in 1581 in five folio volumes.

DU MOULIN, JOHN PHILIP (1834-1911). A Canadian Anglican bishop. He was born in Dublin, Ireland, but in early manhood came to Canada. He was educated at Trinity University, Toronto, and in 1863 was ordained a priest of the Church of England in Canada. He was curate of St. John's Church, London, Ontario, in 1862-66; of Holy Trinity Church, Montreal, in 1866-71; incumbent of St. Thomas's Church, Hamilton, Ontario, in 1872-75; and rector of St. Martin's Church, Montreal, in 1875-82. While incumbent at Hamilton, he was elected Bishop of Algoma, but declined the preferment. In 1882-86 he was rector and canon of St. James's Cathedral, Toronto, and in 1885-96, sub-dean of St. Alban's Cathedral in that city. He was a delegate to the Lambeth Conference, London, England, in 1897 and a delegate to the Pan-Anglican Congress in the same city in 1908. In 1906-07 he had a prominent part in compiling a hymnal for the use of the Church of England in Canada. He was widely known as an able and eloquent preacher. His principal publications were *Two Pillars of Empire* (1904) and *The Eternal Law* (1906), being the Slocum lectures for 1901 at the University of Michigan.

DUMOURIEZ, dū'mōō'rē'ā', CHARLES FRANÇOIS (1739-1823). A French general and poli-

tician, born at Cambrai, Jan. 25, 1739. His father was a commissary officer in the French army, and young Dumouriez obtained a commission and fought in the Seven Years' War, retiring in 1763 with the rank of captain, a small pension, and the cross of St. Louis. After some years spent in travel Dumouriez was appointed quartermaster-general to the Corsican expedition by the Duke de Choiseul and was later sent on a secret mission to Poland. Though employed by D'Aiguillon, the successor of Choiseul, Dumouriez fell into disgrace while on a mission in Sweden and spent the last months of Louis XV's reign in the Bastille and the Château at Caen. Under Louis XVI, however, he was made commandant at Cherbourg, where he commenced the creation of a great naval establishment. In 1788 he was made a major general, and on the outbreak of the Revolution attached himself at first to Lafayette and Mirabeau, but in 1790 became connected with the Jacobin Club and managed to secure a command in Normandy. In 1792 he became Minister of Foreign Affairs, but resigned to become lieutenant general of the Army of the North. He operated successfully against the Duke of Brunswick, who received a severe check at Valmy (September 20) and was forced to abandon the invasion of French territory. He then pressed into the Austrian Netherlands and defeated the enemy at Jemappes, on Nov. 6, 1792. This was the period of his highest power, and for the moment he was the greatest man in France. In 1793, after several small successes, Dumouriez was checked in his career of conquest by the Austrians under Prince Coburg in the battle of Neerwinden. Denounced at Paris as a traitor, he refused to appear before the bar of the Assembly to answer to the charges. After vainly trying to induce his army to embrace the cause of royalty, Dumouriez in despair deserted to the Austrians, with a few of his officers. The Convention set a price of 300,000 francs upon his head. After wandering through many countries of Europe, he finally settled in England, where he died in exile at Turville Park, near Henley upon-Thames, March 14, 1823. Besides a multitude of pamphlets, Dumouriez wrote *Mémoires du général Dumouriez* (Hamburg, 1796) and *La vie et les mémoires du général Dumouriez* (3d ed., Paris, 1822-24). Consult: Welschinger, *Le roman de Dumouriez* (ib., 1890); Griffiths, *French Revolutionary Generals* (London, 1891); Chuquet, *La première invasion prussienne* (Paris, 1886); Valmy (1887); *La retraite de Brunswick* (1887); *Jemappes* (1890); *La trahison de Dumouriez* (1891); Rose and Broadley, *Dumouriez and the Defence of England Against Napoleon* (London, 1908).

DUN. See DON.

DŪNA, dū'nā, or SOUTHERN DVINA (in contradistinction to the Dvina of northern Russia). A river of West Russia, rising in a lake in the southwestern part of the Government of Tver, 9 miles from the source of the Volga (Map: Russia, B 3). It flows in a semicircle at first southwest, and then northwest, finally forming the boundary between Courland and Livonia, and empties into the Gulf of Riga 10 miles below Riga. Its length is about 650 miles. The upper course of the river lies in a broken country, giving rise to numerous rapids. It is navi-

gable through almost its entire length. Ocean steamers can ascend only to Riga, but smaller vessels reach Dunaburg. The traffic on the Dūna is very considerable at high water, 2,000,000 tons being annually transported. Some of the tributaries are navigable. The Dūna is connected by the Beresina Canal with the Dnieper, and is free of ice in its lower course for over 240 days in the year.

DŪNABURG, dū'nā-bōōrk (Russian official name since 1893, Dvinsk). A district town and fortress in the Russian Government of Vitebsk, situated on the Duna, 110 miles southeast of Riga, and 332 miles southwest of St. Petersburg (Map: Russia, C 3). It is a fortress of the first class and is situated at the junction of three important railway lines, . . . St. Petersburg, Warsaw, Libau, Riga, and Vitebsk. The chief manufacturing establishments are distilleries, tobacco and match factories, flour mills, brick works, tanneries, and limekilns. The commerce in flax and timber is considerable. Dunaburg was founded by the Livonian Knights in 1278, in 1561 became a part of Poland, and in 1772 was incorporated with Russia. Dunaburg was bombarded by the French in 1812 and was occupied by the allied Prussian and French forces under Macdonald in the same year. Pop. (main town), 1910, 89,884; . . . sub-urbs), 110,912, of which over . . . ewes.

DUNA-FÖLDVÁR, dū'nō-fēld'vār (Hung., earth-walled fortress on the Danube, so called from its situation). A town of Hungary in the County of Tolna, on the right bank of the Danube, about 50 miles south of Budapest (Map: Hungary, F 3). It is in an . . . region, and its trade by river includes . . . and wines. Pottery is made here, and there are sturgeon fisheries. Pop., 1900, 12,117; , 1910, 12,087, mostly Magyars.

DUNANT, dū'nān', (JEAN) HENRI (1828-1910). A Swiss author and philanthropist, founder of the Red Cross Society (q.v.). He was born in Geneva and conceived the idea of founding a society for aiding wounded soldiers while visiting the scene of the battle of Solferino. He wrote *Un souvenir de Solferino* (1862; 5th ed., 1871; Eng. trans. by Mrs. D. H. Wright as *The Origin of the Red Cross*, 1911), and delivered lectures . . . chief in war before the Society of Public Utility in Geneva. Soon afterward a meeting was held in that city which resulted in the Geneva Convention (1864) and the establishment of a permanent international committee. In 1864 the coöperation of 10 governments had been obtained, and the Red Cross Society was officially established (Aug. 22, 1864). M. Dunant bestowed his entire fortune on various charities. In 1901 he shared the first Nobel peace prize with Frédéric Passy (q.v.). Besides the work already mentioned, he wrote the following: *Fraternité et charité internationales en temps de guerre* (1st to 7th ed., 1864); *L'Esclavage chez les musulmans et aux Etats-Unis de . . .* (1863); *La rénovation de l'Orient . . .*

DUNBAR' (Gael., Castle Point). A royal, parliamentary, and municipal burgh, and ancient seaport of Waddington-shire, Scotland, on an eminence of the rocky coast near the mouth of the Firth of Forth, 20½ miles east-northeast of Edinburgh (Map: Scotland, F 4). There are two harbors, partly barred by reefs. Pop. (municipal burgh), 1901, 3581; 1911, 3346. The principal industries are the manufacture of

farming tools, distilling and brewing, and rope making. On the high rocks at the entrance to the new harbor are the ruins of a castle, built about the middle of the ninth century and, from the end of the eleventh century, the chief seat of the earls of March. It was once an important stronghold in resisting English invasion. Edward I took it in 1296, after defeating the forces under Baliol, and Edward II fled thither after the battle of Bannockburn. It was successfully defended in a siege of six weeks against the Earl of Salisbury by Black Agnes, Countess of Dunbar, in 1339; it sheltered Queen Mary and Bothwell in 1567, and in the same year it was destroyed by the regent Murray. In September, 1650, Cromwell, at the "Race of Dunbar," defeated the Scottish army under Leslie.

DUNBAR, PAUL LAURENCE (1872-1906). An American poet of African race, born at Dayton, Ohio, and educated in the public schools of Dayton. He worked as a printer in New York and on the staff of the *Harvard Library*. He appeared in public as a reader of his poems, which have been collected under the titles of *Oak and Ivy* (1893); *Majors and Minors* (1895); *Lyrics of Lowly Life* (1896); *Poems of Cabin and Field* (1899); *Lyrics of the Hearth Side* (1899); *Candle-Lightin' Time* (1902); *Lyrics of Love and Laughter* (1903); *Li'l Gal* (1904); *Lyrics of Sunshine and Shadow* (1905). His more mature work, when in dialect, deserves the generous commendation given it. He also wrote a volume of short stories, *Folks from Dixie* (1897); a novel, *The Uncalled* (1898); *The Sport of the Gods* (1902). Consult L. K. Wiggins, compiler, *Life and Works of Paul Laurence Dunbar* (1907); *Complete Poetical Works*, with W. D. Howells's introduction to "Lyrics of Lowly Life" (new impression, New York, 1913).

DUNBAR, WILLIAM (c.1465-1525?). The greatest of the old Scottish poets. Of his life very little is known, but he was born between 1460 and 1465, probably in East Lothian, and is supposed to be the William Dunbar who entered St. Andrews University in 1475 and graduated as M.A. in 1479. He cannot be traced at all during the next 21 years. From his poem, "Visitation of St. Francis," we learn, however, that he joined the Order of Franciscans and afterward left it. He says that as a begging friar he traveled from Berwick to Canterbury and crossed over to Picardy. By 1500 he was in the service of James IV of Scotland. In that year he was granted an annual pension of £10, afterward increased to £20 and then to £80. In 1501 he seems to have visited England in the train of the ambassadors sent thither to conclude the negotiations for the King's marriage to Margaret Tudor. Early in 1503, before the Queen's arrival, he composed, in honor of the event, an allegorical poem entitled "The Thistle and the Rose." He seems now to have lived chiefly about court, writing poems, and sustaining himself with hope of preferment in the church. After the ruinous defeat at Flodden, and the confusion consequent on the King's death and a prolonged regency, Dunbar's name disappears altogether. He probably died between 1520 and 1530. As a poet, he possessed a variety of gifts. He is at times as rich in fancy and color as Spenser in the *Faerie Queene*, as homely and shrewd and coarse as Chaucer in the *Miller's Tale*, as pious and devotional as Cowper in his *Hymns*, and as wildly grotesque in satire as

Burns in his *Death and Doctor Hornbook*. Besides the beautiful allegory cited above, Dunbar wrote another called "The Golden Targe." He is at his very best in the satires "The Two Married Women and the Widow" and "The Dance of the Deadly Sins." His *Works* were edited by Laing (2 vols., 1834); also by Small and Mackay, for the Text Society (Edinburgh, 1884-93). Consult Schipper, *William Dunbar, sein Leben und seine Gedichte* (Berlin, 1884), and the *Cambridge History of English Literature*, vol. ii (New York and London, 1907-13).

DUNBARTON (Scotland). See DUMBARTON.

DUNBIRD, or DUNKER. See POCHARD.

DUNCAN, ADAM, first VISCOUNT DUNCAN OF CAMPERDOWN (1731-1804). A British admiral, born at Lundie, Forfar, Scotland. He was educated at Dundee, and entered the navy in 1746, became lieutenant in 1755, and fought against the French at Gorée, Africa. In 1761 he was promoted to be commander, served in the expedition against Belle Isle, and in the capture of Havana in the following year. He was engaged at the battle of Cape St. Vincent in 1780 and at the relief of Gibraltar two years later. He was promoted to be rear admiral of the blue in 1789 and became vice admiral in 1793. In 1795 Duncan was made commander in chief of the United English and Russian squadron in the North Sea and shortly afterward was appointed admiral. In the Nore Mutiny (1797) Duncan, who was a man of herculean proportions, 6 feet 4 inches in height, and strikingly handsome, quelled the disaffection on his vessel by displays of personal strength and the force of his personality. His strategical blockade of Texel with two ships was one of the most effective ever made, and on Oct. 11, 1797, near Camperdown, he destroyed the Dutch fleet on its way to invade Ireland and took Admiral De Winter prisoner. Ten days later he was created Baron of Lundie and Lord Viscount Duncan of Camperdown. While traveling to Edinburgh, he died suddenly at Cornhill Inn, near Coldstream. Consult: James, *Naval History of Great Britain* (London, 1822); Yonge, *History of the British Navy*, vol. i (ib., 1863); Earl of Camperdown, *Admiral Duncan* (ib., 1898).

DUNCAN, ISADORA (1880-). An American dancer, born in San Francisco. She was for a time a dancing teacher in New York and attempted to revive classic, i.e., simple Greek, dances, but she was not warmly received. In Munich, Berlin, and Paris, however, where she later lived, she became very popular. At Grünwald, near Berlin, she established, under the immediate charge of her sister Elizabeth, a dancing school for girls from 4 to 14 years of age, where they receive free board and schooling. Miss Duncan was the first to popularize the barefoot dance in simple free draperies—the antithesis of ballet and toe dancing—and was particularly happy in her dances interpretative of Beethoven, Gluck, and Chopin. In 1913 she went into temporary retirement when the two children of her union with Gordon Craig (q.v.) were carried by a runaway motor car over the Seine embankment and drowned.

DUNCAN, JAMES (1857-). An American granite cutter and labor leader, born in Kincardine Co., Scotland, whence he removed to the United States. He was secretary of the New York branch (1881) and of the Baltimore branch

(1884) of the Granite Cutters' International Association, of which he became national secretary-treasurer in 1895. He led a successful educational campaign in the union and then (1900) conducted the great strike in the granite-cutting industry for an eight-hour day. He was vice president of the American Federation of Labor (1894), represented the American labor movement in the British Trades Council at Bristol, England (1898), and was a member of the Industrial Department of the Civic Federation (1901).

DUNCAN, JOHN (1796-1870). A Scottish theologian and Hebraist, born at Aberdeen and educated at Marischal College. He was ordained in 1836 and, after preaching in Milton Church, Glasgow, was sent to Pest, in 1840, as a missionary for the conversion of the Jews, and counted among his converts the celebrated Dr. Edersheim and the Rev. Dr. Adolph Saphir, afterward a minister of the English Presbyterian Church, London. After his return from Pest, in 1843, he was until his death professor of Oriental languages in New College, Edinburgh. Consult the *Life* (Aberdeen, 1872) by David Brown; the *Recollections of Duncan* by Stuart; and Knight's *Colloquia Peripatetica* (1870; 5th ed., 1879).

DUNCAN, JOHN (1805-49). An African traveler, born near Kirkcubright, New Brunswick. He entered the army at the age of 17 and served until 1842, in which year he went to Africa as a member of the Niger expedition and took a prominent part in negotiating treaties with the natives. The party subsequently was stricken with fever, and of the 300 men who had embarked in this expedition, only five, including Duncan, succeeded, after almost incredible hardships, in reaching England. In 1844 Duncan penetrated from the western coast to Whydah and subsequently passed through Dahomey to Adofidiah. In 1847 he published an interesting account of this expedition in the work entitled *Travels in Western Africa in 1845 and 1846*, and in the same year he contributed to Bentley's *Miscellany* a paper in two parts, entitled *Some Account of the Late Expedition to the Niger*. In 1849 he was appointed Vice Consul at Whydah.

DUNCAN, LOUIS (1862-1916). An American electrical engineer, born in Washington, D. C. He graduated from the United States Naval Academy in 1880, but resigned from the navy in 1887; meanwhile he had taken advanced work at Johns Hopkins University, and in 1885 received a Ph.D. During the Spanish-American War he was major of the first volunteer engineers. He was associate in, and associate professor of, applied electricity at Johns Hopkins (1887-98), and head of the department of electrical engineering at Massachusetts Institute of Technology (1902-03). In 1895 he was president of the American Institute of Electrical Engineers. He is author of many articles on engineering topics in scientific journals.

DUNCAN, NORMAN (1871-1916). An American author, brother of Robert Kennedy Duncan. He was born at Brantford, Ontario, Canada, and was educated at the University of Toronto. From 1897 to 1901 he was a member of the staff of the New York *Evening Post*, and in 1907-08 he was correspondent for *Harper's Magazine* in Asia Minor and Egypt. He was professor of rhetoric at Washington and Jefferson College (1902-06) and adjunct professor of

English literature at the University of Kansas (1908-10). *Doctor Luke of the Labrador* (1904) and his other stories of the Newfoundland coast life are sympathetic and skillful. His writings include: *The Soul of the Street* (1900); *The Way of the Sea* (1903); *Dr. Grenfell's Parish* (1905; 2d ed., 1911); *The Mother* (1905); *The Adventures of Billy Topsail* (1906); *The Cruise of the Shining Light* (1907); *Every Man for Himself* (1908); *Going Down from Jerusalem* (1909); *The Suitable Child* (1909); *Higgins* (1909); *Billy Topsail & Company* (1910); *The Measure of a Man* (1911); *The Best of a Bad Job* (1912); *Finding his Soul* (1913).

DUNCAN, ROBERT KENNEDY (1868-1914). An American chemist, brother of Norman Duncan. He was born at Brantford, Ontario, Canada. After graduating from the University of Toronto in 1892 he studied at Clark and Columbia universities; then he taught physics and chemistry in several secondary schools and was professor of chemistry at Washington and Jefferson College from 1901 to 1905. In the latter year he accepted the chair of industrial chemistry at the University of Kansas, in 1910 he became also director of industrial research, and he added to this work similar responsibilities at the University of Pittsburgh. He became visiting lecturer at Clark University in 1911. Besides contributing articles to popular and scientific magazines, he edited the *New Science Series* and wrote *The New Knowledge* (1905); *The Chemistry of Commerce* (1907); *Some Chemical Problems of Today* (1911).

DUNCAN, SARAH JEANETTE. See COTES, SARAH JEANETTE.

DUNCAN, THOMAS (1807-45). A Scottish portrait, historical, and genre painter, born at Kinclaven, Perthshire. Despite early indications of artistic talent, he was apprenticed by his father to a law writer. He studied painting in the Trustees' Academy, Edinburgh, under William Allen. His first pictures to attract wide attention were a "Scotch Milkmaid" and the "Death of Old Mortality," exhibited in London at the Royal Institution in 1829. In 1830 he was made a member of the Royal Scottish Academy, in which he became a professor, first of color, then of drawing. In 1830 he was made master of the Trustees' Academy, Edinburgh, and in 1843 an associate of the Royal Academy. He died in Edinburgh, on April 25, 1845. Duncan devoted himself chiefly to portraiture, but his best-known works are genre and historical pictures, taken from the history and life of the Scottish people. One of his most popular paintings is "Prince Charles and the Highlanders Entering Edinburgh," exhibited in London in 1840, into which he introduced the portraits of distinguished Scotchmen of the day. Two of his best-known genre pictures are the "Waefu' Heart," from the ballad of "Auld Robin Gray" (South Kensington Museum) and "Anne Page and Slender" (National Gallery of Scotland). The most interesting of his portraits is his own, exhibited in 1846, after his death. It was purchased by 50 Scottish artists and presented to the Royal Scottish Academy. Duncan's drawing was careful and graceful, and his paintings show some gift of color. Both as teacher and painter he exercised considerable influence over his immediate successors. (Consult: Redgrave, *Dictionary of Artists of the English School* (London, 1878); Armstrong, *Scottish Painters*

(ib., 1888); Caw, *Scottish Painting* (Edinburgh, 1908).

DUNCANSBY (dŭn'kanz-bī) **HEAD** (the Vervedrum of Ptolemy). A promontory 210 feet high, forming the northeast extremity of Caithness, Scotland, 1½ miles east of John o' Groat's House (Map: Scotland, F 1). It is noted for its extensive sea view, cliff scenery, and interesting geological phenomena.

DUN'CIAD, **THE** (from Eng. *Duns, dunse, dunce*, originally from *Duns man*, follower of John *Duns* Scotus, hence subtle reasoner, quibbler, ultraconservative, stupid man). A satirical poem by Alexander Pope (q.v.). It was published, in 1728, in three books; to these, in 1741, a fourth book was added, and for the original hero, Lewis Theobald, Pope substituted Colley Cibber.

DUNCKER, dŭn'kēr, **MAXIMILIAN WOLFGANG** (1811-86). A German historian. He was born in Berlin and studied there and at Bonn, where he became involved in the democratic movements and was imprisoned. He became professor of history at Halle in 1842, a member of the German National Assembly in 1848, professor at Tübingen in 1857, was lecturer on politics to the Prince of Prussia in 1861-66, and became director of the Prussian archives in 1867. His principal work is *Geschichte des Altertums* (5th ed., 1878-83, 7 vols., N. S. 1884-86, 2 vols.). Among his further publications are *Origines Germanicæ* (1840) and *Zur Geschichte der deutschen Reichsversammlung* (1849). Consult Haym, *Das Leben Max Dunckers* (1891).

DUN'COMBE, **THOMAS SLINGSBY** (1796-1861). An English politician. He studied at Harrow, served in the army in 1812-19, and was elected to Parliament from Hertford in 1826, lost this seat in 1832, and sat for Finsbury from 1834 until his death. He assisted in carrying the Reform Bill and became a prominent member of the extreme Liberal party. In 1842 he presented to Parliament the Chartist Petition. In 1844 Sir James Graham, the Home Secretary, denounced the opening of the letters of W. D. Duncombe vehemently denounced, in the House of Commons, the adoption of the post-office spy system on English soil. Consult *Life and Correspondence of Thomas Slingsby Duncombe* (London, 1868).

DUNDALK, dŭn-dak'. A municipal borough and seaport, the capital of the County of Louth, Ireland, beautifully situated at the mouth of the Castletown River, 54 miles north of Dublin (Map: Ireland, E 2). It is overlooked on the northeast by the Carlingford Mountains. Dundalk is the chief outlet for the produce of the counties of Louth, Monaghan, and Cavan, and is in daily steam communication with Liverpool. Besides large railway locomotive works, there are breweries, distilleries, tanneries, flax and jute spinning mills, and iron-rolling works. The town has several educational institutions, including a public library, as well as an old parish church, and an imposing Roman Catholic chapel, modeled after King's College chapel of Cambridge. There are large cavalry barracks here. Pop., 1901, 13,076; 1911, 13,128. Edward Bruce took Dundalk in 1315 and made it the seat of his court until his death, in 1318, on the battlefield at Faughart. The city was captured by the Puritans under Cromwell in 1649 and by Schomberg in 1699.

DUNDAS'. A town in Wentworth Co., On-

tario, Canada, 5 miles from Hamilton, on the Toronto, Hamilton, and Buffalo, and the Grand Trunk railroads (Map: Ontario, E 7). The Desjardins Canal connects it with Lake Ontario. The public park contains 25 acres. The manufacturing industries include tanneries, a building, a quarry, knitting factory, flour mill, and manufactured products include small tools, baskets, gloves, malt, clothing, doors, hosiery, machine tools, barber supplies, church and school furniture. Hydroelectric power is available. Pop., 1901, 3,173; 1911, 4,299.

DUNDAS, **HENRY**, first **VISCOUNT MELVILLE AND BARON DUNIRA** (1742-1811). A British statesman. The fourth son of Robert Dundas, Lord President of the Scottish Court of Session, he was born at Edinburgh, and received his education at the high school and university. He was called to the Scottish bar in 1763 and was successively appointed Deputy Advocate and Solicitor-General. In 1774 he was returned to Parliament for the county of Edinburgh, and in the following year was appointed Lord Advocate for Scotland. Two years after he was made Keeper of the King's Signet for Scotland. His successful career in Parliament was marked by ability rather than political consistency. In opposition to his constituents he allied himself with the party in power and became a strenuous supporter of Lord North's administration as one of the most obstinate and cynical defenders of the war with the American colonists. When Lord North resigned in 1782, Dundas continued to hold the office of Lord Advocate under the Rockingham ministry, and under the Shelburne ministry he became Treasurer of the Navy. In 1781-82 his investigation of Indian affairs originated the reform movement which led to the impeachment of Warren Hastings in 1786. He subsequently was the ablest coadjutor of Pitt, under whose ministry he became President of the Board of Control and principal Secretary of State for the Home Department (1791), where he displayed great harshness towards all Radical demonstrations in Great Britain and frustrated the well-known and ridiculous treasurer of the year 1795. He also held a great number of other offices. When Pitt resigned in 1801, Dundas did the same. In 1802, under the administration of Addington, he was elevated to the peerage under the titles of Viscount Melville and Baron Dunira. In 1806 he was tried for "gross malversation and breach of duty" while acting as Treasurer of the Navy, but in spite of the splendid array of talent against him he was acquitted on all the charges. After this he took little part in public affairs, but spent most of his time in retirement in Scotland.

DUNDAS, **SIR JAMES WHITLEY DEANS** (1785-1862). An English admiral. He entered the navy in 1799 and in 1806 became commander. He was flag captain successively to Sir Thomas Parker and Sir Philip Dunham, and became rear admiral in 1841, and commander in the Mediterranean in 1852, when he became vice admiral. In the Crimean War he was chief naval commander and transported the army to the scene of action. His operations against Sebastopol were severely criticized, and in 1855 he was superseded by Sir Edward Lyons. Two years later he was promoted to the rank of admiral. He married his cousin Janet Dundas in 1808 and added her name to his own. He was made C.B. in 1839.

DUNDAS, SIR RICHARD SAUNDERS (1802-61). An English naval officer, educated at Harrow and at the Royal Naval College. He commanded a vessel in the first war with China. In 1853 he was made a rear admiral and two years later, upon the resignation of Napier, was appointed commander in chief of the Baltic fleet which bombarded Sveaborg (Aug. 9-11, 1855) and blockaded the Gulf of Finland. He became K.C.B. in 1856 and vice admiral in 1858.

DUNDAS, ROBERT, LORD ARNISTON (1685-1753). A Scottish jurist. He was admitted a member of the Faculty of Advocates at Edinburgh in 1709 and soon gained a reputation as an able lawyer. In 1717 he was appointed Solicitor-General, in 1720 became Lord Advocate, and in the next year Dean of the Faculty of Advocates. He was a member of Parliament from Midlothian from 1722 to 1737 and was an active opponent of Lord Hay's administration of Scottish affairs in 1734. In 1737 he became a judge of the Court of Session of Scotland and from 1748 until his death was Lord President of the court.—His son **ROBERT** (1713-87), also a jurist, was educated at Edinburgh University and studied Roman law at Utrecht and Paris. His career was remarkable in its similarity to that of his father. He was admitted to the Scottish bar in 1737, became an eloquent advocate, and in 1742 was appointed Solicitor-General, which office he resigned in 1748 upon becoming dean of the Faculty of Advocates. He was appointed Lord Advocate in 1754 and was elected to Parliament from his father's old constituency in Midlothian in the same year. In 1760 he succeeded Robert Craigie as Lord President of the Court of Session and took the office just seven years after it had been left vacant by the death of his father. He retained the position until his death. Consult *Omond, Lord Advocates of Scotland* (1883), and *The Arniston Memoirs* (1883).

DUNDAS STRAIT. A passage separating Melville Island from Coburg Peninsula (q.v.), northern Australia (Map: South Australia, Northern Territory, C 1). It is 18 miles in width.

DUNDEE' (Gael. *Dun Tarr*, fort on the Tay). A royal, parliamentary, and municipal burgh and seaport, in Forfarshire, Scotland, on the left bank of the Firth of Tay, the estuary of the river Tay, 10 miles from the sea, and 59 miles by rail north-northeast of Edinburgh (Map: Scotland, F 3). The greater part of it is situated on a slope; there is a water frontage of 4 miles. A handsome esplanade skirts the estuary for 2½ miles. The new streets are wide and well laid out. The most striking architectural features are the town hall (1734), in the Roman Ionic style, with a spire 140 feet high; the Albert Institute, including a free library, picture galleries, museum, and several halls, in fifteenth-century Gothic; the royal exchange (1853-56) in the Flemish Pointed style of the fifteenth century; the corn exchange, the infirmary, the judiciary and sheriff-court buildings, the post office, the Town Churches (three under one roof), with the old tower, 156 feet high, restored in 1873; St. Paul's Episcopal Church, in Decorated Gothic, with a tower and spire 211 feet high; a new orphan asylum; University College, opened in 1893 and affiliated with St. Andrews University; Kin-naird Hall (for public meetings), and the Technical Institute (opened in 1888). Dundee

sends two members to Parliament. In 1889 it was raised to the rank of a city. It owns its water, gas, and electric supplies, which net it a substantial profit; maintains cemeteries, markets, and public baths. The docks are owned and operated by the Dundee Harbour Trustees. Dundee has several public parks, the Baxter Park, on a beautiful slope to the eastward of the town, is 37 acres in extent; another, to the westward of the town, occupies the hill of Balgay and is finely wooded and beautifully laid out, its area being about 36 acres; adjacent to it is Lochee Park, of 25 acres. There are several smaller parks.

Dundee is the chief seat in Great Britain of the manufacture of coarse linen fabrics (osnaburghs, sheetings, ducks, dowlas, drills, canvas, and cordage). Of still greater importance is the jute manufacture; many varieties of fabric are made, from the coarsest nail bagging to carpets of great beauty. The jute, flax, and hemp manufactures employ some 50,000 hands. Some of the mills are among the finest in the world. Dundee is also famous for its manufactures of confectionery and marmalade. It is the seat of the formerly important whale and seal fishing industry. Shipbuilding (both wood and iron) and machine making are carried on to some extent. Dundee has splendid harbors in addition to the tide harbor, several large wet docks, two graving docks, and a jetty for vessels drawing more than 24 feet of water. Shipping entered and cleared, in 1912, 354,554 tons. The number of vessels belonging to the port has declined in recent years. The exports include the textiles mentioned above and machinery, millwork, and spirits. The imports include wheat, flour, flax, jute, hemp, timber, sugar, paper-making materials, oilseed cake, mineral ores, etc. Dundee's products are shipped principally by rail; in 1912 the imports amounted to £7,011,286, while the exports were £1,623,632. Dundee became in 1912 the second port in importance in Scotland. It is the seat of a United States consul. At the entrance of the Firth, one of the largest iron bridges ever constructed has been built across the Tay. It was opened in 1887 and is more than 2 miles long. In 1901 the population was 161,173. In 1914 the burgh of Broughty Ferry was annexed to Dundee, increasing the latter's area to 5964 acres and its population, according to the 1911 census, to 176,062. In population Dundee is the third city in Scotland. Dundee was made a royal burgh by William the Lion about 1200. Its strong fortifications made it of the highest military importance, and in the wars between the Scotch and the English it was taken repeatedly by both parties. It was partially destroyed by John of Gaunt in 1385 and was pillaged by Montrose in 1645. In 1651 General Monk sacked and burned the town and massacred 1000 of its inhabitants. From the important part it played in the Reformation, Dundee gained the name of the "Scottish Geneva." Consult *Thomson, History of Dundee* (Dundee, 1874), and Peterson, *Saint Andrews and Dundee* (ib., 1893).

DUNDREARY, LORD. An amusing caricature of the English nobility, in Tom Tay-

DUNES

AN EMBRYONIC SAND DUNE, developing on a beach at Chicago, Ill. The grass which acts as a sand-binder is the Sand Reed (*Ammophila*).

A LIVING SAND DUNE, at Dune Park, Ind., advancing over swamps and forests, destroying almost everything in its path.

lor's *Our American Cousin*. Originally a minor part, it was gradually developed by E. A. Sothern until it became the most prominent character in the play.

DUN'DRUM BAY. An inlet on the east coast of Ireland, in County Down, 5 miles to the south of Downpatrick. It is about 10 miles wide at its entrance (Map: Ireland, F 2). In the inner bay is the famous strand of the champions where ancient Ultonians achieved athletic preëminence.

DUNE (AS., OHG. *dūn*, Ger. *Düne*, Fr. *dune*, from Ir. *dūn*, hill, fort, Welsh, *din*, Gall. *dūnon*; ultimately connected with AS., Icel. *tún*, Eng. *town*, OHG. *zūn*, Ger. *Zaun*, hedge). The name first given to the sand hills or mounds which stretch along the seacoast of the Netherlands and the north of France. The English term Downs (q.v.) has a similar meaning. Drift sand hills or dunes are found in all regions of sandy, arid soil which are subject to brisk and high winds. Along the sandy Atlantic coast of North America, from Cape Cod to Cape Canaveral and beyond, such wind-built hills of moving sands are common features. In this region they are found from 5 to 40 feet in height, while on the coasts of the Bermudas or Bahamas they reach a height of 100 to 200 feet. They also characterize portions of the shores of Lake Michigan, the Caspian Sea, Sea of Aral, and other inland water bodies.

Concerning the growth of the dunes of the Netherlands, W. Chambers's *Tour in Holland* says: "At low water, when the beach is exposed to the action of the winds from the German Ocean, clouds of sand are raised into the air and showered down upon the country for at least a mile inland; and, this constantly going on, the result is, that along the whole line, from Haarlem to about Dunkirk or Calais, the coast consists of sandy mounds of great breadth, partially covered with grass and heath, but unfit for pasture or any other purpose, and these are the landmarks which protect the coast. In some places these dunes look like a series of irregular hills; and when seen from the tops of the steeples, they are so huge as to shut out the view of the sea." See DESERT; ÆOLIAN ACCUMULATIONS.

DUNEDIN, *dūn-ē'dīn*. The capital and chief port of the Province of Otago, South Island (Map: New Zealand, S. I., C 6). It is a thoroughly modern city built among steep hills, overlooking an excellent harbor on the east shore of the island. Encircling the city is a forest preserve called the Town Belt, and beyond it many beautiful suburbs. There are numerous handsome buildings, including churches, the post office, hospital, town hall, atheneum and museum, mechanics' institute, and several libraries. Dunedin is the seat of Otago University, opened in 1871, has faculties of arts, medicine, chemistry, and mineralogy; also of a training college for teachers. The United States has a resident consular agent. The city is the see of an Anglican and a Roman Catholic bishop. It is in regular steam communication with Melbourne and is connected by rail with the principal cities on the island. The principal articles of export are grain, potatoes, and wool, and cold-storage meat. Woolen goods are the most important articles of trade and manufacture. Much gold is mined near by. From its foundation by an association of members of the Free church of Scotland, in 1848, the city rapidly

increased in importance, chiefly after the year 1861, when the discovery of extensive gold fields in the district caused a sudden increase of population. 1911, 64,237.

DUNE VEGETATION. Plants which inhabit sandy areas that are or have been worked over by the wind. Although commonly regarded as composed of xerophytes only, they are found to include mesophytes upon dunes that have been established for centuries. The pioneer conditions upon dunes are very severe, not so much on account of the absence of water, as because of the instability of the sand. Upon such moving areas not only are the plants pronounced xerophytes, but the most successful species are those that are able to withstand submergence and to multiply by means of underground stems which root at frequent intervals and so extend over increasingly wide areas. Probably the most characteristic beach-dune plant is the sand-reed or Marram grass (*Ammophila* or *Psamma*), found throughout the Northern Hemisphere, and often planted to aid in holding dunes. Equally successful among woody plants are various species of small willows, while shrubby cherries and sumachs are abundant in many parts of the United States.

The most interesting of all dunes are the wandering dunes, since they present peculiar ecological conditions. As a dune moves over a region, it often submerges the vegetation in its pathway, whether it be lowland or upland. Very few plants can adapt themselves to the new conditions, though a few species, especially willows, are able to do so. As a dune passes on, the buried plant societies often appear again as soil lines, and sometimes dead trees are shown—a sort of natural graveyard.

On the moving sand the vegetation is very scanty, in spite of the fact that there is a very constant although rather small water supply a few inches below the surface. The vegetation consists of antecedent plants, such as the willows, poplars, and a few other trees and shrubs that by sending out roots from the buried stems surmount the advancing sand, together with grasses and other subsequent plants that are able to germinate upon the surface of the dune. Among the antecedent trees that are able to survive are some surprisingly mesophytic species, like the linden. If a dune for any reason ceases its movement, vegetation easily finds a foothold, and either the grasses multiply and form a continuous turf, or more commonly a forest, in which pines and small oaks are often prominent, becomes established. Once fixed and covered with plants, the dune vegetation in temperate climates rapidly advances in richness and luxuriance. These facts show that it is the instability of dunes, rather than their xerophytic character, which excludes plant life. In tropical regions, the dune plants, of course, belong to quite different species, yet their ecological characteristics are the same. There, as in the United States, xerophytic grasses, with long underground stems which have the power to flourish when half buried in the sand, are still the dominating forms. Dunes that have remained fixed for many centuries may be again started into motion by the destruction of their vegetation. This is usually brought about through the agency of man, either by means of the removal of the forest by cutting the trees too closely or by forest fires, or, where there are no trees, by pasturing too closely. In New

Zealand sheep pastured upon the grass-covered dunes during dry seasons strip the turf so completely that the wind is able to start the sand beneath into motion, forming ever-increasing dunes that rapidly submerge valuable pasture lands. The remedy consists of planting the windward slope with a grass, such as the Marram grass, mingled with some shrub, like one of the willows, and when movement has ceased, Experience in Belgium and countries shows that only forested dunes can be relied upon to remain in place and not cause damage by submerging agricultural lands.

Cowles, *Ecological Relations of the Vegetation of the Sand Dunes of Lake Michigan* (Chicago, 1899); Massart, *Essai de géographie botanique des districts littoraux et alluviaux de la Belgique* (Brussels, 1908); Cockayne, *Report on the Sand Dune Area of New Zealand* (N. Z., 1911). See EDAPHIC; DESERT.

DUNFERMLINE, dūn-fēr'lin (Gael., fort of the alder-tree pool). A royal burgh and city, and the chief town of the western district of Fifeshire, Scotland, situated on high ground 3 miles from the Firth of Forth, 16 miles northwest of Edinburgh (Map: Scotland, E 3). It was a place of note before the end of the eleventh century, and some interesting fragments of its ancient regal and ecclesiastical magnificence remain. What is called Malcolm Canmore's tower is a mass of shapeless ruins, but the south wall of the palace of the Stuarts exists, overhanging the romantic glen of Pittencrief. Of the abbey, the frater hall or refectory and a tower and arched gateway remain. Queen Margaret was married to Malcolm Canmore here in 1070 and influenced the founding (1075) of a Benedictine priory, afterward made an abbey, where now rest the dust of some of Scotland's most illustrious dead, notably Queen Margaret and Canmore, Alexander I and his Queen, David I, Malcolm IV, and Robert Bruce and his Queen. Among the noteworthy buildings are the Carnegie library, Carnegie baths, St. Margaret's Hall, the Abbey Church, high school, county and corporation buildings. The staple trade of the town is damask-linen weaving, which took its rise about the middle of the eighteenth century. There are also works for the spinning of linen yarn, and several large factories where steam and hand loom weaving is carried on. There are also large collieries and lime-works, iron foundries, breweries, dyeworks, and fire-clay works. Pop. (municipal burgh), 1901, 25,250; 1911, 28,103. The palace, of which but few vestiges remain, was frequently visited by the court, while the abbey became the burial place of the Scottish kings. Charles I was born in the palace in 1600. Dunfermline was made a royal burgh in 1588. In the seventeenth century the town was burned by the soldiers of Cromwell. The modern history of Dunfermline is chiefly remarkable in connection with the rise of Scottish dissent; Ralph Erskine, brother of Ebenezer (q.v.), and one of those who joined the latter in the secession movement in 1737, was assistant minister there; and 15 years later the resistance of the presbytery of Dunfermline to the attempt to force a minister upon a congregation led to the formation of the Relief Church. (See PRESBYTERIANISM.) Consult Chalmers, *Historical Account of Dunfermline* (Edinburgh, 1844-59).

DUNFORD, PORT. See PORT DUNFORD.

DUNGARVAN. A municipal borough, seaport, and bathing place in Waterford Co., Ireland, 28½ miles west-southwest of Waterford (Map: Ireland, D 4). Brewing and the manufacture of woollens are the important industries. The fisheries are also productive, and the town has an export trade in grain, butter, and cattle. Dungarvan has the remains of an Augustinian abbey founded in the seventh century by St. Garvan. Pop. 1901, 4850, 1911, 4977.

DUNG BEETLE. A name given to various beetles of the family Scarabidae, belonging chiefly to the genera *Canthon*, *Copris*, *Phanaeus*, *Aphodius*, *Geotrupes*, and *Trox*. All these beetles breed in dung, either in situ, or which they have transported in pellets or balls to burrows in the ground. Thus they are useful as scatterers and disposers of offensive matter. Some forms carry their scavenging propensities still further and feed on decaying animal matter and on fungi. The American tumblebugs belong to the first three genera enumerated, and are the forms most familiar to us, because they are so frequently seen rolling their pellets along roadways and in pastures. Both sexes unite in the labor of rolling the balls, within which the eggs are laid. *Canthon laevis* is a dull, blackish-brown beetle, the commonest species of its genus. *Phanaeus carnifex* of eastern North America has a copper-colored thorax and green elytra; the head of the male is horned. *Copris carolina* is a black horned species, occurring along the Atlantic slope as far north as Massachusetts. The genus *Aphodius* has more than 100 species in America, frequenting the dung of cattle and horses in pastures. The adults are on the wing during warm days of autumn. The most common species is *Aphodius fime-tarius*, with red wing covers. *Geotrupes* digs breeding holes in the earth, into which the female rolls chunks of the dung as food for the young. The skin-beetle genus, *Trox*, feeds on decaying animal hoofs and hair. Dung beetles have long attracted the attention of man. The Egyptians contemplated them with veneration, placed them in the tombs together with their dead, sculptured and painted them on their sarcophagi, and made imitations of them of various materials, often of precious stones. The ball of dung the Egyptians supposed represented the earth, and the beetles the sun; moreover, they were thought to be a race of males, and hence were the symbol of warriors. This last superstition was carried to Rome. See SCARABÆIDÆ and illustrations on Plate of BEETLES. Consult Ward, "A Popular Treatise on Egyptian Scarabs," in *Art and History* (London, 1901); also Budge, Petrie, and Wallis.

DUNGENESS. A headland forming the southern extremity of Kent, England, 10 miles southeast of Rye, inclosing the Romney Marshes (Map: England, H 6). It has a fort and a lighthouse.

DUNGEON. See DONJON.

DUNGLISON, ROBLEY (1798-1869). An American physician. He was born at Keswick, England, was educated in Germany, and in 1824 was called to the chair of medicine in the University of Virginia. From 1833 to 1836 he was professor in the University of Maryland, and from 1836 to 1868 in the Jefferson Medical College in Philadelphia. He was a diligent student, and was the author of a large number of excellent medical books, among which are:

Human Physiology (1832; 5th ed., 1844); *Medical Dictionary* (1833; 23d ed., 1903); and *General Therapeutics and Materia Medica* (1836; 6th ed., 1857). Consult *Memoir of Dr. Robley Dunglison* by his son, Dr. R. J. Dunglison (1870).

DUNITE (named from *Dun*, the Scotch for "hill"). A rock composed almost entirely of olivine. See PERIDOTITE.

DUNKARDS, or **DUNKERS**. See CHURCH OF THE BRETHREN.

DUNKER, dŭn'kēr, WILHELM (1809-85). A German mineralogist. He was born at Eschwege, Hesse, and was educated at Göttingen. He was professor of mineralogy and geognosy at Marburg from 1854 until his death. In association with Hermann von Meyer he founded (1846) the scientific periodical entitled *Paleontographica, Beiträge zur Naturgeschichte der Vorwelt*, of which thirty volumes had been published up to 1883. His principal works comprise the *Beiträge zur Kenntniss des norddeutschen . . . und dessen Versteinerungen* (with Friedrich Koch, 1837); *Monographie der norddeutschen Wealdenbildung* (1846); *Index Molluscorum Guineensium* (1853); *Mollusca Japonica* (1861); *Index Molluscorum Maris Japonici* (1882).

DUNKIN, CHRISTOPHER (1811-80). A Canadian statesman. He was born in England, and was educated at London and Glasgow Universities. In early manhood he came to the United States and in 1834 was appointed an instructor in Greek at Harvard University. The following year he removed to Montreal, and in 1837-38 he edited the *Morning Chronicle* of that city. When Upper and Lower Canada were united by the Act of 1841 Dunkin was made Assistant Provincial Secretary, an office which he held until 1847. In the meantime he studied law, was called to the bar of Lower Canada in 1846, and soon had a large practice in Montreal. His reputation was greatly increased in 1853 when he argued before the Legislative Assembly against a proposed measure for reducing alleged exorbitant rents of the seigniors of Lower Canada. In 1857-61 and 1862-68 he was a Conservative member of the Legislative Assembly. In 1864 he procured the passage of the "Dunkin Act" to restrict the liquor traffic by local popular control. He opposed confederation and during the parliamentary session of 1865 was the ablest of the speakers in opposition to that change. In 1867 he was made provincial treasurer of Quebec. In 1869 he was again elected to the Dominion Parliament, and became Minister of Agriculture in the first administration of Sir John Macdonald after confederation. In 1871 he resigned that position and was appointed a puisne judge of the Superior Court of Quebec.

DUNKIRK, dŭn'kĕrk (Celt., church on the dunes), *Fr.* DUNKERQUE, dŭn'kĕrk'. A fortified seaport of France, capital of an arrondissement in the Département of Nord, on the Strait of Dover, 15.5 miles north of Paris, and 28 miles northeast of Calais (Map: France, N., H 1). The town is connected by railway and canal with the principal manufacturing centres of Belgium and France. It is surrounded by ramparts, and ditches, and forms part of an extensive system of fortifications, which includes Calais and Gravelines. The harbor, which is approached by a natural roadstead, is accessible to the largest vessels. There are four dry docks,

and the quays are over five miles in length. The town is well built, the streets spacious and well paved, the houses chiefly of brick. The principal streets converge at the Place Jean Bart, in the centre of which is a statue of Jean Bart by David d'Angers. Near by is a belfry (290 feet) containing a fine chime of bells. It was once the western tower of Saint-Eloi, but is now separated from that church by a street. Saint-Eloi is a Gothic structure of the sixteenth century, having a handsome though rather incongruous frontispiece in its more recent Corinthian portico. Other architectural features are the chamber of commerce, the fine modern town hall, and the college and theatre. Dunkirk has a fine museum, picture gallery, and public library. There are manufactories of soap, starch, beer, beet sugar, cordage, and leather; also metal foundries, distilleries, and shipbuilding yards. Dunkirk ranks third among the seaports of France (fourth among the ports, counting Paris). The value of its imports and exports combined in 1911 was 1,042,900,000 francs. Its cod and herring fisheries are actively prosecuted. The United States is represented by a consular agent. The immediate vicinity of Dunkirk has a dreary and uninteresting appearance. Pop. (commune), 1906, 38,287; 1911, 38,891. In 1851 Dunkirk had 29,080 inhabitants.

Dunkirk owes its origin, it is said, to the church built by Saint-Eloi in the seventh century in the midst of a waste of sand hills or dunes, and hence its name, "Church on the Dunes." It shared the fortunes of Flanders, coming successively under Burgundian, Austrian, and Spanish rule. It was burned by the English in 1388. It was taken from the Spaniards by the French (under Turenne) in 1658 and made over to Louis XIV but was sold to Louis XIV by the French in 1662. By the Treaty of Utrecht in 1713 the French were compelled to destroy the fortifications of Dunkirk, which were again restored, however, in 1783. Consult Derode, *Histoire de Dunkerque* (Lille, 1852), and Sautter, *La Flandre maritime* (Paris, 1900).

DUNKIRK, a city in Jay Co., Ind., 30 miles east of Marion, on the Pennsylvania Railroad (Map: Indiana, D 2). It is in the gas belt and has large glass factories. It is governed, under a charter of 1893, by a mayor, elected quadrennially, and a council. It owns its water works. Pop., 1900, 3187; 1910, 3031.

DUNKIRK. A city and port of entry in Chautauqua Co., N. Y., 41 miles southwest of Buffalo; on Lake Erie, and on the Lake Shore and Michigan Southern, the Pennsylvania, the Erie, the New York, Chicago and St. Louis, and the Dunkirk, Allegheny Valley and Pittsburgh railroads (Map: New York, A 6). It has a good harbor, protected by a breakwater, and a large lake trade. The industrial plants include locomotive works, axe and steel factories, radiator and gas-engine works, planing mills, shirt factories, etc. Among the features of interest are the high-school building, public library, Brooks Memorial Hospital, Gratiot Park, and Washington Park. Dunkirk was settled about 1809, was incorporated as a village in 1837, and was declared a city in 1880. It is governed, under a revised charter of 1909, by a mayor, elected biennially, who controls the appointments to the civil service commission, and board of health; and by a common council

of five members, elected by the voters of the city at large. The board of education is elected by the people. The water works and electric-light and power plants are owned by the municipality. Pop., 1890, 9416; 1900, 11,616; 1910, 17,221; 1914 (U. S. est.), 19,607.

DUNLAP, WILLIAM (1766-1839). An American artist and author. He was born at Perth Amboy, N. J. In 1784 he went to London and for several years studied painting with Benjamin West. On his return to America he engaged chiefly in dramatic and literary work, producing *The Father*, his best play, in 1789, and becoming manager of the Park Theatre, New York, in 1798, where *André* was played the same year. His enlightened administration, which contributed essentially to the development of dramatic art, was continued for several years, but finally resulted in theatrical bankruptcy. Many of his plays have never been published. His interest later to art, he gained reputation in the country by religious paintings, or which "Death on the Pale Horse" is most famous. He was one of the founders and an early vice president of the National Academy of Design. The most noteworthy of his publications is his *History of the American Theatre* (1832). He also wrote *Life of George Frederick Cooke* (1813) and *Charles Brockden Brown* (1815); *History of the Rise and Progress of the Art of Design in the United States* (1834); and *Thirty Years Ago: or, the Memoirs of a Water Drinker* (1836). The Dunlap Society, founded in 1886, has reprinted *The Father* and *André*. Consult A. Marble, *Heralds of American Literature* (1907).

DUNLIN (a corruption of *dunling*, from *dun*, in reference to the color + diminutive *-ling*), or **REDBACK**. A sandpiper of the Northern Hemisphere, which migrates annually between arctic breeding grounds and the tropics, and is an object of eager sport in the late spring, when it appears in large compact flocks not very difficult to approach. The plumage changes greatly with the season, in winter being prevailingly gray, while in summer the back is chestnut-red, each feather with a black centre, a broad white band covers the dusky wing, and a broad jet-black band marks the abdomen, while the white breast and throat are thickly streaked. It breeds in Europe from Scotland northward, in Kamchatka, in Alaska, and eastward to Greenland. The European bird is systematically named *Pelidna* or *Erolia alpina alpina*, and is known in Great Britain as dunlin, purre, oxeye, etc. The American and Siberian examples are separated in a subspecies, *alpina sakhalina*, locally known to gunners as blackheart, ox-bird, oxeye, redback, etc.

DUNLOP, JOHN COLIN (c.1785-1842). A Scottish critic and author, born at Rosebank, near Glasgow. He passed most of his life in study, read widely in Greek, Latin, Italian, Spanish, and French, and embodied his knowledge in various histories, of which only *The History of Prose Fiction* (1814; revised 1816) is important. This work, though very uneven in quality, has never been superseded. At least at the time of its publication the sections dealing with Italian and Spanish fiction were found especially valuable. It was translated into German in 1851, and revised in 1888 (London and New York).

DUNMORE. A borough in Lackawanna Co., Pa., adjoining Scranton, on the Erie and

the Lackawanna railroads (Map: Pennsylvania, K 3). It contains St. Mary's Academy, St. Joseph's Infant Home, and homes for the aged and friendless. The borough is the centre of extensive anthracite coal, brick, stone, and silk interests. Under a charter of 1862, the government is vested in a burgess, elected every four years, a borough council, and administrative officials, the majority of whom are chosen by popular vote. Dunmore was settled in 1835 and incorporated in 1862. Pop., 1890, 8315; 1900, 12,583; 1910, 17,615; 1914 (U. S. est.), 19,757.

DUNMORE, JOHN MURRAY, EARL OF (1732-1809). An English Governor of Virginia. He sat in the House of Lords in 1761-69 as a representative peer of Scotland. In 1770 was appointed Governor of the Colony of New York, and in 1771 of that of Virginia. He dissolved the House of Assembly in 1772, 1773, and 1774—on the last occasion because of the resolution of that body to observe June 1, the day for the closing of the port of Boston, as a time of public fast. He commanded a division of Virginia troops in Dunmore's War (q.v.), upon the conclusion of which he made an important treaty with the Indians. In April, 1775, he removed a part of the powder stores from Williamsburg to the warship *Magdalen*. Thereupon the colonists in large numbers volunteered for military service under the direction of Patrick Henry. During a session of the House, in June, a riot occurred, and Dunmore transferred the seat of government to the man-of-war *Fowey*, 12 miles off Yorktown. The burgesses finally declared that the Governor had abdicated, and vested a committee of safety with executive powers. Dunmore equipped a flotilla, with which he unsuccessfully attacked Hampton on October 25. He burned Norfolk on Jan. 1, 1776. On July 8 he was forced by Andrew Lewis (q.v.) from the station which he had taken on Gwynn's Island, in the Chesapeake, and shortly afterward, having burned the smaller vessels and sent the remainder to the West Indies, returned to England, where he sat in the House of Lords 1777-78. From 1787 to 1796 he was Governor of the Bahamas. Consult Campbell, *History of Virginia* (1860).

DUNMORE'S WAR. A war in 1774 between the Indians and the whites on the western frontiers of Virginia, so called from Lord Dunmore, then Governor of Virginia, who was accused, apparently with little justice, of having caused it in order to prevent the Indians from taking part in the revolution in England. The murder of Captain Logan, a noted Mingo chief (see LOGAN, JOHN), on April 30, 1774, by a man named Greathouse and his associates, was the occasion for the outbreak of general hostilities, and for several months thereafter there were frequent Indian attacks of unusual ferocity. The Virginian government promptly raised a force of about 3000, and in September, General Lewis (see LEWIS, ANDREW), with about 1200 men, marched to the mouth of the Great Kanawha, there to await a second force of about 1300 under Lord Dunmore, who was to start from Fort Pitt. Dunmore subsequently changed his plans, however, and on October 10 he fought alone the important battle of Point Pleasant, which virtually closed the war. (See POINT PLEASANT, BATTLE OF.) Soon afterward Dunmore made a treaty with the Indians, whereby the latter

agreed not to hunt south of the Ohio and not to molest . . . the river. But for this war, it is . . . the migration of settlers to the West would have been almost wholly checked until after the close of the Revolution, and that, in consequence, the western boundary of the United States might have been fixed by the Treaty of 1783, at the Alleghany Mountains. The war is sometimes called "Cresaps War," from Captain Michael Cresap, who was unjustly charged with having murdered Logan's family. Consult Roosevelt, *Winning of the West* (vol. i, New York, 1889), and Perkins, *Annals of the West* (Pittsburgh, 1857).

DUNMOW (dūn'mō) FLITCH OF BACON.

A prize instituted at Dunmow, in Essex, England, in 1244, by Robert de Fitzwalter, on the following conditions: "That whatever married couple will go to the priory, and, kneeling on two sharp-pointed stones, will swear that they have not quarreled nor repented of their marriage within a year and a day after its celebration, shall receive a flitch of bacon." The prize was first claimed in 1445, two hundred years after it had been instituted. Only five presentations were made up to 1751, and the flitch was not again claimed till 1855. From 1860 to 1891 there were seven awards. More awards have been made since then. Consult Andrews, *History of the Dunmow Flitch* (London, 1887).

DUNN, GANO (1870-). An American electrical engineer born in New York City. He graduated from the College of the City of New York in 1889 and from the engineering department of Columbia in 1891. He was in the service of the Western Union Telegraph Company from 1886 to 1891 and then of the Crocker-Wheeler Company, of which he was vice president and chief engineer from 1898 to 1911; and in 1911 he became vice president and head of the . . . and construction work of J. G. White & Co., Inc., New York. He was president of the New York Electrical Society (1900-02), vice president (1901-03, and 1905-07) and president (1911-14) of the American Institute of Electrical Engineers, and vice president of the International Electrical Congress at Turin (1911). In 1914 he received an honorary M.S. from Columbia University. He is author of various papers on electrical subjects.

DUNN, SAMUEL ORACE (1877-). An American transportation specialist, born at Bloomfield, Iowa. He learned the printing trade after graduating from high school, was editor of the *Quitman (Mo.) Record* (1895-96) and associate editor of the *Maryville (Mo.) Tribune* (1896-1900); from 1900 to 1904 was reporter, and later editorial writer, on the *Kansas City Journal*, and in 1904-07 was connected with the *Chicago Tribune* as railroad editor and editorial writer. In 1907-08 he was managing editor of the *Railway Age*, and thereafter editor of the *Railway Age Gazette*. He is author of *The American Transportation Question* (1912) and *Government Ownership of Railways* (1913).

DUNNE, EDWARD FITZSIMONS (1853-). An American lawyer and political leader, born at Waterville, Conn. He spent three years at Trinity College, Dublin, and graduated from the Union College of Law and was admitted to the bar in 1877. He was circuit court judge of Cook Co., Ill., from 1892 to 1905, when he was elected mayor of Chicago. He became well known for his advocacy of a municipal-ownership

policy and was chosen the vice president of the National Civic Federation. In 1907 he returned to the practice of law. He was presidential elector in 1900 and . . . at large to the Democratic National Convention in 1908. He was elected Governor of Illinois for a four-year term in 1913, defeating Charles S. Deneen.

DUNNE, FINLEY PETER (1867-). An American humorist. He was born in Chicago, Ill., and, having obtained a common-school education there, served from 1885 to 1891 as a reporter on various newspapers. From 1891 he was editorially connected with the Chicago newspaper press as successively city editor of the *Times* (1891-92), member of the *Evening Post* and *Times-Herald* staffs (1892-97), and editor in chief of the *Evening Journal* (1897-1900). He first attracted attention by the publication in the *Times-Herald* of a series of sketches in which, through the medium of one Martin Dooley, publican of Archey Road, he passed humorous comment upon a variety of subjects. With the Spanish-American War he more prominently developed a vein of political and social satire, and upon the publication of *Mr. Dooley in Peace and in War* (1898), a volume of selections, attained wide popularity in America and England. *Mr. Dooley in the Hearts of his Countrymen* (1898), *Mr. Dooley's Philosophy* (1900), *Mr. Dooley's Opinions* (1901), *Observations by Mr. Dooley* (1902), and *Mr. Dooley Says* (1910) appeared in continuation. In his shrewd analysis of fault and foible, his ability to "speak truth smiling," and speak it with a certain distinctive gusto, "Mr. Dooley" occupies the leading place among latter-day American humorists.

DUN'NET HEAD. The northernmost point of the mainland of Great Britain in Caithness, Scotland, . . . western entrance to the Pentland . . . Scotland, E 1). It is 280 feet high, is crowned with a lighthouse, 67 feet in height, visible 24 miles, and is the ancient Tarvedrum, or Orcus Promontorium.

DUN'NING, ALBERT ELIJAH (1844-). An American Congregationalist clergyman, born at Brookfield, Conn. He graduated at Yale University (1867) and at Andover Theological Seminary (1870). . . the pastorate of the Highland . . . Church in Boston from 1871 to 1881, he acted as general Sunday-school secretary for Congregationalist churches from 1881 to 1889, and was editor in chief of the *Congregationalist* from 1889 to 1911. He conducted many parties of tourists to the Holy Land. His principal publications are the following: *The Sunday-School Library* (1883); *Bible Studies* (1886), translated into many foreign languages; *Congregationalists in America* (1894).

DUNNING, JOHN, BARON ASHBURTON (1731-83). An English lawyer and statesman, born at Ashburton (Devonshire). He studied law at the Middle Temple, was called to the bar in 1756, obtained a high legal reputation, became Solicitor-General in 1768, and in the same year was returned to Parliament for Calne. He very strongly opposed the policy of the ministry in connection with the American Colonies, representing that policy as, "Resist, and we will cut your throats; submit, and we will tax you." In 1774 and again in 1780 he was reelected to Parliament. In 1782 became a member of the Privy Council, and was appointed Chancellor of the Duchy of Lancaster. He wrote *A Defense of*

the *United Company of Merchants of England Trading to the East Indies* (1762) and has been credited with the authorship of *A Letter to the Proprietors of East India Stock* (1764), a pamphlet entitled *Inquiry into the Doctrines Lately Promulgated Concerning Juries, Labels, etc.* (1764), and a joint share in the *Letters of Junius* (1769-72) (q.v.). Consult Roscoe, *Lives of Eminent British Lawyers* (London, 1838).

DUNNING, WILLIAM ARCHIBALD. An American university professor and writer on political science. He was born at Plainfield, N. J., graduated from Columbia University in 1881, and spent four years in postgraduate work. Between 1886 and 1903 he was fellow, lecturer, instructor in political science and history, adjunct professor, and professor of history at Columbia, where he became professor of history and political philosophy in 1904. He was managing editor of the *Political Science Quarterly* (1894-1903). In 1913 he was president of the American Historical Association. Besides magazine articles, he is author of: *Essays on the Civil War and the Reconstruction* (1898); *History of Political Theories, Ancient and Mediæval* (1902); *History of Political Theories from Luther to Montesquieu* (1905); *Reconstruction, Political and Economic* (1907); *Carl Schurz's Political Career, 1869-1906*, with Frederic Bancroft (1908); *Paying for Alaska* (1912).

DUN'NOCK (ME. *donek*, from *donnen*, *dunnen*, *dun* + diminutive *-ek*, *-ock*; so called from the color). A familiar folk name in Scotland and parts of England for the hedge sparrow (q.v.), one of the commonest of British warblers.

DUNNOTTAR CASTLE. A ruined castle on the Kincardineshire coast, Scotland, 1½ miles south of Stonehaven. It occupies the top of a rock, 4½ acres in extent and 160 feet high, overhanging the sea, with a deep dry chasm between it and the mainland. It is approached by a steep winding path. It was the ancient seat of the Keiths, earls marischal of Scotland. In 1296 Wallace is said to have taken the rock and the kirk of Dunnottar from the English. During the Commonwealth the regalia of Scotland were hid in the castle from the Republican army, and before the garrison surrendered to Cromwell's troops in 1651 the regalia were removed and secreted in the church of Kinneff. In the time of Charles II and James II the castle was one of the state prisons, where the Covenanters were confined. It was dismantled after the rebellion of 1715, on the attainder of the last earl marischal.

DUNN'VILLE. A town and port of entry of Haldimand Co., Ontario, Canada, on the Grand River and the Grand Trunk Railway, 43 miles west of Buffalo (Map: Ontario, E 8). The manufacturing establishments include knitting mills, flour mills, machine shops, a planing mill, a foundry, a cannery, an evaporator, woolen mills; and among the manufactured products are hammocks, bricks, cement blocks, and boats. The town owns its sewerage system. Pop., 1901, 2106; 1911, 2861.

DUNOIS, du'nwā', JEAN, COUNT OF (1403-68). A brilliant French soldier, known as "the Bastard of Orleans." He was the natural son of Louis, Duke of Orleans, brother of Charles VI, and of Marietta d'Enghien, the wife of Aubert Flamene, Lord of Cauny. He was brought up in the house of his father, who was murdered in 1407. Attached to the Armagnac faction, Dunois was taken prisoner by the Burgundians

when they captured Paris in 1418 and was not released until two years later. His friends then advised him to enter the church, but his own tastes led him to a military life and he attached himself to the party of the Dauphin Charles. His first battle was that of Baugé, in 1421. He was endowed with the seignior of Vaubernais in Dauphiné, and married in 1422 Marie Louvet, the daughter of the Dauphin's favorite adviser. The same year Charles became King and made Dunois a councilor and grand chamberlain. In 1424 he was present at the battle of Verneuil, but the retirement of his father-in-law Louvet, through the intrigues of the Constable de Richement, led Dunois to withdraw for a time from the service of Charles. In 1427, however, he was again prominent and in the relief of Montargis, besieged by the English, in September of that year, laid the foundation of his military renown. He next undertook the defense of Orléans, which he bravely sustained until the arrival of Joan of Arc with aid. Joining their forces for the reconquest of France, Dunois and the Maid of Orleans entered upon an almost unbroken succession of victories which freed France from the English. The capture of Joan of Arc before Compiègne was a sore blow to Dunois, nor could he save her from being burned at Rouen, though he gallantly attempted a diversion in Normandy. Resuming the campaign, Dunois took Chartres in 1432, and, forcing Bedford from in front of Lagny, he laid the way open to Paris. His operations with Richemont in Lower Normandy and around Paris hastened the conclusion of the Treaty of Arras (1435), by which Philip of Burgundy abandoned the cause of England and went over to Charles VII. Dunois refused to sign the treaty because it did not stipulate for the release of his brother, the Duke of Orleans. He was instrumental in expelling the English from Paris and held a place of honor in the royal entry, November, 1437. After procuring the liberation of the princes of Orleans in 1439, Dunois was more or less involved, for their sake, in the political intrigues of the great nobles against the King, known as the Praguerie. Many new honors and titles were, however, conferred upon him, and between 1446 and 1448 he was employed by Charles VI on diplomatic missions to Flanders, Burgundy, Savoy, and Rome. The war between England and France, having begun again, in 1449, Dunois was named lieutenant general of Normandy, and in a campaign lasting only a year and six days he took all the important strongholds of the English and expelled them from Normandy. Charles VII designated such a conquest as miraculous, and employed Dunois to do the same in Guienne in 1451, where his triumph was equally complete. It has been maintained that, as a reward, Dunois was declared legitimate, but this is not proved. During the wars between Charles VII and the Dauphin Louis, Dunois held Normandy in the name of the King, and was present at the battle of Castillon in 1453. The last years of the great soldier were spent in state affairs. His services and abilities were at first recognized by Louis XI, who employed him in negotiations with the Duke of Brittany in 1462, but as he did not enjoy the confidence of the King, Dunois in 1465 placed himself at the head of the League of the Public Weal and was active in negotiating the Treaty of Saint-Maur. He died at the Château of Hay, Nov. 24, 1468, and was buried in the church of Notre Dame de Cléry, Louis XI

being present at the funeral. Consult the contemporary chronicles by Monstrelet, Basin, and Berry; also Aimé-Champollion, *Louis et Charles d'Orléans* (Paris, 1844); Beaucourt, *Histoire de Charles VII* (6 vols., ib., 1885-91); Vallet de Viriville, *Histoire de Charles VII* (ib., 1862). Dunois appears in Scott's *Quentin Durward*.

DUNOON, dūn-ōon'. One of the most frequented sea-bathing places and summer residences in the west of Scotland, situated in the southeast of Argyllshire, on the Firth of Clyde, 9 miles west of Greenock (Map: Scotland, D 4). Dunoon Castle, of which only a small part remains, stood on a conical hill near the pier and was once a royal palace and strong fortress. Dunoon was the birthplace of Burns's "Highland Mary" (Mary Campbell), and a statue of her by D. W. Stevenson was erected here in 1898. Pop. (police burgh), 1901, 6779; 1911, 6859.

DUNRAVEN, WINDHAM THOMAS WYNDHAM-QUIN, fourth EARL OF (1841-). An English politician. He was born at Adare Abbey, was educated at Christ Church, Oxford, entered the army in 1865, and was war correspondent for the *Daily Telegraph* in Abyssinia and during the Franco-Prussian War. In Lord Salisbury's administrations of 1885-86 and 1886-87 he was Undersecretary of State for the Colonies and from 1888 to 1890 was chairman of the House of Lords Committee on Sweating. He was chairman of the Irish Land Conference (1902-03) and president of the Irish Reform Association, and served in the war in South Africa. He competed unsuccessfully for the America's cup in the international yacht races in 1893 and 1895 with the *Valkyrie II* and *Valkyrie III*. He wrote: *The Great Divide, the Upper Yellowstone* (1874); *The Irish Question* (1880); *Self-Instruction in the Theory and Practice of Navigation* (1900); *The Legacy of Past Years* (1911); *Canadian Nights* (1914).

DUNSINANE, dūn'si-nān'. One of the Sidlaw Hills, in the east of Perthshire, Scotland, 1012 feet high, 7 miles northeast of Perth, facing Birnam Hill (q.v.) (Map: Scotland, E 3). On the summit are the faint remains of "Macbeth's Castle," an ancient fortification.

DUNSMUIR, JAMES (1851-). A Canadian capitalist and statesman. He was born at Fort Vancouver, Washington Territory, and was educated at Nanaimo, B. C., Hamilton Collegiate Institute, Ontario, and the Military School, Blackburg, Va. He afterward was trained for business while with his father, who found and developed the first important coal measures in British Columbia, and whom he succeeded as president and chief owner of important coal companies and also as president of the Esquimalt and Nanaimo Railway, which he sold to the Canadian Pacific Railway in 1905. His business enterprises in various directions brought him great wealth. In 1898-1902 he was a Conservative member of the Provincial Legislature; in 1900-02 he was Premier and President of the Council. In 1906-09 he was Lieutenant Governor.

DUNS SCOTUS. One of the greatest thinkers of the Middle Ages, who by his acumen, displayed in his defense of the doctrine of the Immaculate Conception won for himself the title Doctor Subtilis. He was born either in 1265 or in 1274. The place of his birth is not known. England, Scotland, or France may claim him. He entered the Order of Friars Minor, studied at Oxford, and in 1301 became professor of theology there. His prelections were attended by crowds

of auditors. In 1304 he removed to Paris and in 1308 to Cologne, where he died in November of the same year. The general principles of the Scotist system of philosophy deviate only in some points from the Thomist doctrine. (See AQUINAS.) Duns Scotus establishes the necessity of revelation on the ground that reason does not teach us clearly and plainly the highest end of our existence—the intuition of God. In addition to natural knowledge or philosophy, revelation is necessary to enable man to know the fullness of truth and, on the basis of this knowledge, to fulfill his eternal destiny. Revelation therefore supplements and perfects this knowledge, and consequently no contradiction can exist between them. The object of theology is God, as God *sub ratione deitatis*, while philosophy only treats of God in so far as He is the first cause of things. Theology is a practical science, directed not so much to the removal of ignorance as towards the furtherance of our salvation. The incorruptibility and immortality of the human soul he holds to be a truth of faith, which cannot be demonstrated by reason. Duns Scotus was a realist in philosophy (see NOMINALISM) and yet maintained that universals do not need to be differentiated to become individuals. Individuality is original, and the universal, while preexisting in God's plan, has real existence only in the individuals, from which, by abstraction, the human mind comes to cognize it. The supreme function of mind is, for Duns Scotus, not thought, as for Thomas Aquinas, but will; and he maintained the position by acutely pointing out that clear thought presupposes the exercise of will in attention. Will is free, he taught, and not determined by motives. This is true, not only of men, but of God, who therefore does not, as Thomas Aquinas asserts, command an action because He sees it to be good, but makes it good by commanding it. Duns Scotus had numerous adherents, the best known among whom was Francis of Mayro (died 1325). But when the revival of learning came, the "Dunsmen," or followers of Duns, "raged in every pulpit" against the new classic studies and brought their name into such disrepute as stupid obstructionists that the word "dunce" (= Dunsman) came to mean a "blockhead." The most famous of Duns Scotus's works, besides his commentaries on the Bible and Aristotle, is his commentary on the Sentences of Peter Lombard, called the *Opus Oxoniense*, of which the *Opus Parisiense* is an abridgment. The chief edition of his works is that prepared by his order, and usually assigned to Luke Wadding (12 vols., Lyons, 1639), but it is by no means complete, containing only his philosophical works; nor is it all authentic, as at least one of the volumes is a compilation of lecture notes taken by his hearers. Duns Scotus's works have not received the attention they deserve, and a satisfactory work on his philosophy is still to seek. Consult: Stöckl, *Geschichte der Philosophie des Mittelalters* (Mainz, 1865); Werner, *Duns Scotus* (Vienna, 1881); Pluzanski, *Essai sur la philosophie de Duns Scotus* (Paris, 1887); Siebeck, "Die Willenslehre bei Duns Scotus und seinen Nachfolgern," in *Zeitschrift für Philosophie* (Berlin, 1898); Royce, *Conception of God* (New York, 1898); De Wulf, *Histoire de la philosophie médiévale* (Paris, 1905; Eng. trans., London, 1909); also the histories of philosophy by Ueberweg, Erdmann, and Windelband.

DUN'STABLE, JOHN (c.1370-1453). The earliest of the old English composers, probably born at Dunstable, in Bedfordshire. He is buried at St. Stephen's, Walbrook (London). Of his life absolutely nothing is known. In 1847 a three-part chanson, *O Rosa bella*, was discovered, and until the last years of the nineteenth century it remained the only known work of Dunstable. Just before the end of the century several of this composer's works were discovered in the libraries of Oxford, London, Modena, and Bologna. But most important was the discovery of six volumes of manuscript in the library of the cathedral of Trent by F. X. Haberl. In these many of Dunstable's works have been preserved. They include masses, motets, antiphones, and French and Italian songs with instrumental accompaniment. The study of these compositions disclosed the existence of a highly developed art in England during the early part of the fifteenth century, contemporary with and even slightly antedating, the oldest-known French school (Binchois, Dufay).

DUN'STAN, SAINT (925?-988). An English archbishop and statesman. He was born at or near Glastonbury, c. 910 or 925, and was educated by certain Irish scholars living at the school attached to the old monastery of Glastonbury. Dunstan became a learned scholar, and he was also a musician, a painter, and a calligrapher, and a worker in metals. After a short time at court, he became a monk and acquired a great reputation for sanctity. Near the church at Glastonbury he erected a cell, five feet in length by two and one-half in breadth, the floor sunk beneath the surface, while the roof on the outside was only breast high. Here, after distributing all his goods to the poor, for he had inherited riches, he led an ascetic life, and the fame of his sanctity spread. He also devoted himself to the study of Scripture and the Fathers of the Church, and became one of the most learned men of his times. On the accession of Edmund to the throne in 940, Dunstan was recalled to court. The King made him Abbot of Glastonbury (c. 945), and increased the privileges of the monastery. Under Edmund's successor, Edred, Dunstan enjoyed great favor and now began to be regarded as a statesman. He aided Edred in his dealings with the Danes, and instituted reforms in the church. Edred was succeeded by Eadwy in 955. On the day of the King's coronation, Dunstan publicly rebuked him for an uncanonical marriage, and so won his respect and that of his wife's family. He was deprived of his offices and banished (956), and his reforms were checked. He fled to Flanders, where he was well received, and lived in Ghent. He returned to England in 958, and was made Bishop of Worcester; in 959 he became Bishop of London, and in 960 Archbishop of Canterbury. King Edgar, who succeeded Eadwy in 958, heartily sustained Dunstan's reforms, and, seconded by Oswald, Bishop of Worcester, and Ethelwald, Bishop of Winchester, Dunstan with characteristic energy labored efficaciously for the regeneration of the clergy and the moral advancement of the people. Under Dunstan's counsel Edgar's reign was vigorous and successful. On the death of Edgar in 975, Dunstan espoused the cause of Edward the Martyr, and succeeded in placing his favorite on the throne. But Ethelred ultimately prevailed, and the power and influence of Dunstan declined. He retired to Canterbury, and died there May

19, 988. Dunstan was ambitious and persistent but guided by sagacity and far-sighted statesmanship. It is often said that he introduced the Benedictine discipline into England. But his religious reforms were certainly conceived and started before his visit to Ghent, when he had his first opportunity of becoming familiar with the Benedictine Order. No authentic literary work of Dunstan is extant. Consult: *Memorials of St. Dunstan*, edited by Stubbs (Rolls Series, London, 1874, a collection of lives, with a valuable introduction); Lingard, *History and Antiquities of the Anglo-Saxon Church*, vol. ii (London, 1809); Wright, *Biographia Literaria*, vol. i, period (London, 1842).

DUNSTAN, RYNDHAM ROWLAND (1861-). An English chemist, born in Chester and educated at Bedford School. He became demonstrator of chemistry at Oxford in 1884, professor to the Pharmaceutical Society in 1886, lecturer at St. Thomas's Hospital in 1892, and director of the Imperial Institute in 1903. He traveled in the tropics and in 1910 was president of the International Association for Tropical Agriculture and Colonial Development. He and his students made important researches in industrial chemistry, e.g., on aconitine and allied alkaloids and on ammonia compounds. His chief contributions were mostly contributions to technical chemistry (royal and chemical societies) and reports on colonial and tropical industries, such as *Coal Supply of India* (1899), *Agriculture in Asia Minor* (1908), *Cotton Cultivation of the World* (1910).

DUNSTER, HENRY (c.1612-59). An American educator, the first president of Harvard College. He was born at Bury, Lancashire, England, and was educated at Magdalene College, Cambridge, where he was associated with Jeremy Taylor and John Milton. He emigrated to Massachusetts in 1640, and in the same year became the first president of Harvard College, of which since 1637 Nathaniel Eaton had been "professor" or "master." He rendered invaluable service to the college, but in 1654 was forced to resign his office for having publicly opposed the doctrine of infant baptism. He was an able preacher, and was widely known as a profound scholar and Orientalist. Consult Chaplin, *Life of Henry Dunster* (Boston, 1872).

DUNTON, JOHN (1659-1733). An English bookseller and author. In 1685-86 he visited the Massachusetts Bay Colony, and, having seen John Eliot and acquainted himself somewhat with the native tribes, returned to London to establish a prosperous new business at the Sign of the Black Raven. Subsequently he was involved in debts, and his affairs became unbalanced, and published his *Errors and Misdeeds of John Dunton* (1705), a strange mixture of nonsense and valuable information regarding himself and many other persons of the time. He published the *Mercury* (originally the *Athenian Gazette*), from 1690 to 1696, and in 1717 entered into arrangements with Defoe for the publication of another weekly, to be called *The Hanover Spy*. His many political tracts in support of the Whigs were unrecognized by the ministry. His *Letters from New England*, edited by Whitmore, were published in New York in 1867.

DUNTON, THEODORE WATTS. See WATTS-DUNTON, THEODORE.

DÜNTZER, dunt'sēr. JOHANN HEINRICH JOSEPH (1813-1901). A German philologist and

literary historian, born in Cologne. He studied at the universities of Bonn, Cologne, and Berlin, and in 1846 was appointed librarian of the public library in the Catholic gymnasium at Cologne. His publications on philological subjects include: *Die Lehre von der lateinischen Wortbildung* (1836); *Kritik und Erklärung der horazischen Gedichte* (1840-46); *Verzeichniss der römischen Altertümer des Museums Wallraf-Richartz in Köln* (3d ed., 1885); and school editions of *Homer* (2d ed., 1873 et seq.), and *Horace* (with Latin commentary, 1849; with German commentary, 1868-69). He also published more than 20 biographical and critical works on Goethe, of which the biography entitled *Goethes Leben* (2d ed., 1883) has been translated into English by Lyster (1884). His biography of Goethe, and similar works on Schiller, Lessing, and Herder, are characterized by scholarly research and accuracy, but lack inspiration and charm of style.

DUNWOODY, HENRY HARRISON CHASE (1842-). An American meteorologist, born in Highland Co., Ohio. He graduated at the United States Military Academy in 1866. After serving in the Fourth United States Artillery from 1866 to 1869, he was recorder of the Tactics Board at St. Louis, Mo., for two years. He was associated as meteorologist with the Signal Office at Washington for nearly 20 years. He promoted the establishment of weather services in the various States, and systematized the official forecasts and so-called hot and cold wave predictions. In recognition of his important work on the Signal Corps he was promoted to the rank of major in 1889. He was made colonel in 1898, and was retired as brigadier general in 1904. His papers on meteorological subjects include the following: *Decrease of Temperature with Elevation and Reduction of Barometer to Sea Level*; *Tables of Rainfall and Temperature Compared with Crop Production*; *Weather Proverbs*; *Absolute Humidity and Mean Cloudiness in the United States*; *Geographical Distribution of Rainfall in the United States*.

DUODECIMAL SCALE (from Lat. *duodecim*, twelve). The name given to the division of any unit into 12 equal parts, as the division of the foot into 12 inches. See NOTATION; ARITHMETIC.

DU'ODE'NUM. See INTESTINES.

DUOVIRI. See DUUMVIRS.

DUPANLOUP, du'pān'loo', FÉLIX ANTOINE PHILIBERT (1802-78). A French prelate. He was born at St. Félix, Savoy; was ordained priest in Paris in 1825, and became confessor to the Duke de Bordeaux (afterward Count de Chambord) in 1827, and Bishop of Orléans in 1849. Under Louis Philippe he was a leader among the Liberal Catholics; under Napoleon, the foremost champion of the temporal independence of the Pope. Before the Vatican Council and in the Council in 1870 he opposed papal infallibility, but he submitted to the decision of the Council. At the close of the war with Germany he was sent as a representative to the National Assembly, where he favored a constitutional monarchy. Dupanloup became a member of the French Academy in 1854—in 1863 he opposed the election of Littré, at the same time attacking Taine and Renan—and a senator in 1875. He urged the advantage of keeping Latin in the school curriculum, and his best works are *De l'éducation* (1855-57) and *De la haute éducation* (1866). His *Histoire de Jésus*

(1872) was a reply to Renan. His *Œuvres choisies* were published in 1861. He has a fine tomb in the Orléans cathedral. Consult Pelletier, *Monseigneur Dupanloup* (Paris, 1876), and a *Life* (1883; 7th ed., 1894) by Lagrange, Eng. trans. by Lady Herbert (London, 1885).

DUPERRON, du'pā'rōn', JACQUES DAVY (1556-1618). A French prelate. He was born at Saint-Lô, Normandy, the son of Protestant parents, who had to flee soon afterward from Normandy to Bern, Switzerland. He succeeded in winning a position at court, and the protection of the Duke de Joyeuse, and became a Roman Catholic in 1577 or 1578. He was appointed reader to King Henry III, and, though a layman, was at Vincennes, and on the death of Henry III, Duke of Scots, was chosen to pronounce her eulogy. His success in oratory and his ambition led him to take orders. Toward the end of the reign of Henry III he attached himself to the Cardinal de Bourbon, and is said to have sold the latter's secrets to Henry IV, whose conversion to Catholicism was under Duperron's teachings and who made him Bishop of Evreux. With Cardinal d'Ossat, Duperron persuaded the Pope to relieve the kingdom of the interdict, and for his services received the cardinal's hat in 1604. In all theological disputes he took an active part against the Protestants. He wrote many controversial works, some ballads, and an elegy, *L'Ombre de M. l'amiral de Joyeuse* (1588). The *Perroniana* (1666), by Dupuy, is a famous collection of *Ana.* Consult Féret, *Le Cardinal Duperron* (Paris, 1876).

DUPES, DAY OF (Fr. *journée des dupes*). The name given in France to Nov. 11, 1630, because on that day Richelieu foiled the enemies who had nearly succeeded in ousting him from the royal favor.

DUPETIT-THOUARS, du'p't-tē'tō's'ar', ABEL AUBERT (1793-1864). A French naval officer, born near Saumur. In 1839 he completed a voyage around the world as captain of the *Venus*. In 1842 he placed the *Venus* at the Islands, and the following year the whole Society group, under the protection of France. In 1846 he was made vice admiral and in 1849 was elected to the Legislative Assembly. He published *Voyage autour du monde sur la frégate La Venus* (1841-49).

DUPETIT-THOUARS, LOUIS MARIE AUBERT (1758-1831). A French botanist, born at Boumois, near Saumur. In 1792 he accompanied his brother, Aristide Aubert, a naval commander, to Madagascar and the neighboring islands, where he collected numerous botanical specimens. In 1802 he returned to Paris, where he was appointed director of the Royal Institute of Arboriculture. The results of his extensive travels in the Eastern island were published in a series of works of which the publication entitled *Histoire des végétaux recueillis sur les îles de France, de Bourbon et de Madagascar* (1804), is probably the most important.

DUPIN, du'pān', ANDRÉ MARIE JEAN JACQUES (1783-1865). A French lawyer and statesman. He was born at Varzy, in the Department of Nièvre, and studied in Paris. After failing, in 1810, to secure a professorship in law, he devoted himself to active practice at the bar until he was elected, in 1815, a member of the Chamber of Deputies. The publication of his treatise, *De la libre défense des accusés*, caused him to be chosen as counsel for Marshal Ney and others

in the trials for treason and sedition that followed the restoration of the Bourbons. In his pamphlet, *La révolution de 1830*, he endeavored to prove the lawful character of this revolution, and showed himself an ardent defender of the rights of the bourgeoisie. Louis Philippe made him his intimate counselor and procurator general of the Court of Cassation. In 1832 he became a member of the Academy. From 1832 to 1840 he was president of the Chamber of Deputies. He was on the legislative committee which drafted the new constitution after the revolution of 1848, and was president of the Legislative Assembly at the time of the coup d'état. In consequence of the confiscation of the Orléans estates in 1852, Dupin resigned his place and retired for a time from public life; but in 1857 he consented to resume his previous office of procurator general of the Court of Cassation. Of his many important works there may be mentioned the *Glossaire de l'ancien droit français* (1846) and *Opuscules de jurisprudence* (1851). Consult his *Mémoires* (Paris, 1855-63).

DUPIN, CHEVALIER AUGUSTE. The famous character introduced by Edgar Allan Poe as a French detective into several of his short stories, notably *The Murders in the Rue Morgue* and *The Mystery of Marie Rogêt*. The type thus created by Poe was imitated by Conan Doyle in his Sherlock Holmes stories.

DUPIN, LOUIS ELLIES (1657-1719). A French Jansenist and historian. He was born in Paris, became professor at the Royal College. He was exposed to severe criticism because of his attitude towards William Wake, Archbishop of Canterbury, and his attempts to unify the Gallican and English churches. His *Bibliothèque universelle des auteurs ecclésiastiques* (58 vols., 1686-1704) is a complete history of the theological literature of the church and is recognized as a standard work, not only as regards the numerous biographical sketches contained in it, but also because of its exhaustive list of works and the criticisms and other data bearing on them. It and many other of his works were put on the Index. Consult the autobiographic matter in the last volume (1704) of the *Bibliothèque universelle*.

DUPIN, PIERRE CHARLES TROYES. BARON (1784-1873). A French lawyer and politician, brother of André Dupin. He was born at Varzy, in the Department of Nièvre, was educated at the Polytechnic School in Paris, and was afterward employed as inspector general of the Marine Department. He traveled in Ireland for the purpose of studying its industry and commerce, and on his return he published *Voyages dans la Grande-Bretagne* (1820-24). In 1819 he was made professor in the Conservatoire des Arts et Métiers, but his interests became more and more centred in politics, in which he at first showed liberal leanings, but finally took up the cause of the Bourbons. In 1828 he was elected deputy for the Department of Tarn and took part with the moderate opposition, though Charles X had made him Baron four years earlier. After the February revolution of 1848 Dupin was elected member of the Constituent Assembly and later of the Legislative Assembly, and after the coup d'état he became a senator for life. His mathematical treatise, *Développement de géométrie pour faire suite à la géométrie pratique de Monge* (1813),

gave him membership in the Académie des Sciences. His works also include: *Trois forces productives et commerciales de la France* (1825); *Bien-être et concorde des classes du peuple français* (1841); *Forces productives des nations de 1800 à 1851* (1851), the last being his chief work.

DUPELIX, du'plâks', JOSEPH FRANÇOIS, MARQUIS (1697-1764). A French colonial governor-general, celebrated as the opponent of British supremacy in India. He was born at Landrecies, a town not far from Valenciennes, Jan. 1, 1697, and was carefully educated by his father, a rich farmer-general. He made several voyages to America and India, which engendered a remarkable aptitude for business enterprise. In 1720 he went as member of the Superior Council to Pondicherry, where he soon gained a large private fortune. In 1731 he proceeded to Chandernagar as Intendant, and in four years, by his energetic and prudent measures, backed by his own capital, had converted that "decayed and lifeless" town into a thriving port. His success received due recognition, and in 1742 he received the position and title of "General Commandant of the French possessions in India." He soon disclosed the genius of an empire builder, with splendid schemes for territorial acquisition, in which he was ably seconded by his wife, Jeanne Albert de Castro, celebrated in Indian annals as Joanna Begum, the "Princess Joanna." His efforts, however, to form alliances and to strengthen his position received little support from the French East India Company or the French government; he was ordered to cease all outlay on the fortification of Pondicherry, but continued the work mainly at his own expense. In 1745 the struggle known as the War of the Austrian Succession, in which France and England were arrayed against each other, extended to the Indian peninsula. The English East India Company, alarmed at Duplex's activity, had fortified Madras. At first the French were with the help of Labourdonnais, the Isles of France and Bourbon, Duplex repulsed an English attack under Commodore Barnett on Pondicherry, and in 1746 Madras was captured by Labourdonnais, but the results were fruitless, owing to the mutual jealousies of that commander and Duplex. Duplex refused to restore Madras to the English according to a compact entered into by Labourdonnais and sent the latter, on a charge of treason, to France. The same year Duplex was ennobled. He was successful in several brilliant engagements against the Nawab of the Carnatic, who had a personal grievance in connection with the retention of Madras; in 1748 he compelled Admiral Boscawen to raise the siege of Pondicherry after an attack of five weeks. The Peace of Aix-la-Chapelle put an end to hostilities and restored Madras to the English, much to Duplex's chagrin. He nevertheless continued his plans and negotiation for the recovery of southern India, and by 1751 the Carnatic were practically under French domination, and Duplex's dream of making the power of France paramount in India seemed realized. In accordance with tried French method, he treated the natives in a most cordial manner. He married an Indian-born Portuguese woman well acquainted with Hindu life in utmost royalty and splendor, and was profuse in his gifts to

needy natives. But Madame Pompadour in Paris, and other influential people around the King, had no aspirations for French Empire. Troops and supplies were both denied Dupleix, and the English got the upper hand. They knew that Dupleix stood in the way of their success. From the English East India Company came the suggestion that peace and amity might be restored in the Far East if only the French East India Company would recall their firebrand Governor. The French acquiesced, and in 1753 sent Goodhue with a body of troops, ostensibly to assist, but in reality to recall, the great French Proconsul. Dupleix quietly submitted, and the opportunity of a French India slipped by forever.

For the company he had expended \$1,200,000 of his private fortune. In addition he had advanced large sums to his native allies on the security of the revenue of certain districts. He was never repaid. Neglected by his grateful country, the ablest statesman of Louis XV's reign was allowed to die in want and obscurity in Paris, Nov. 10, 1764.

Consult: Malleon, *Dupleix* (Oxford, 1890); Bionne, *Dupleix* (2 vols., Paris, 1881); Guet, *Origines de l'Inde française* (ib., 1892); Fosses, *Dupleix, ses dernières luttes dans l'Inde* (ib., 1889); Cultru, *Dupleix, ses plans politiques; sa disgrâce* (ib., 1901); Weber, *La compagnie française des Indes* (ib., 1904).

DU PLESSIS. See RICHELIEU, DUC DE.

DU PLESSIS-MORNAY, mōr'nā', PHILIPPE (1549-1623). A French Protestant leader, known as "the Huguenot Pope." He was born at Buhy, in Normandy, of nominally Catholic parents, who destined him for the priesthood, but early in life he declared himself a Protestant. His convictions were strengthened by visits to Geneva and Heidelberg, then the centre of Calvinism, during four years of travel (1568-72). On his return to France he attached himself to Coligny, whose fate he escaped on the night of St. Bartholomew. He remained in England for a year, but came back to take up arms for the Huguenot cause. He was captured by Guise at the siege of Dormans in 1575, but, not being able to buy his liberty by the payment of a ransom, he took refuge with the Duke of Bouillon at Sedan. Here he married a young widow, Charlotte Arbaleste. Henry of Navarre sent him to England as a personal representative in 1577, and during this period he wrote a number of theological works. On Condé's death in 1588 he was recognized as the head of the Huguenot faction and had much influence with Henry III, whom he persuaded to legalize the preaching of the reformed doctrine throughout France. He also succeeded in bringing about an understanding between the King and his future successor, and his services were recognized by his appointment as Governor of Saumur, where he made things so difficult for the Catholics that many of them fled from the district. After the murder of Henry III he took a prominent part in the military and other movements which brought Henry of Navarre to the throne, but the latter's conversion ended his official activity. He lost his position in the King's council, but retained his governorship, building at Saumur a Protestant church and college for the education of preachers. His scheme for the organization of French Protestants was adopted by the gathering at Sainte-

Foy in 1594, and he was concerned in the negotiations which led up to the Edict of Nantes. The principal event of his later years was his famous controversy with Duperron, the learned Bishop of Evreux, who accused him of misquotation and garbling in one of his controversial treatises, and met and routed him in a public disputation. Du Plessis was deprived of his office at the time of the Huguenot rising of 1621 and died in retirement on his estate of La Forêt-sur-Sèvre two years later. Consult his *Mémoires et correspondance*, republished in 12 vols. (Paris, 1824-25); also Ambert, *Du Plessis-Mornay* (ib., 1847), and Baird, *The Huguenots and Henry of Navarre* (New York, 1886).

DUPLICATION OF THE CUBE. See CUBE.

DUPLICIDENTATA. See RODENLIA.

DUPLOYÉ, dū'plwā'yā', EMILE (1833-1912). A French stenographer, born at Notre Dame de Liesse (Aisne). He was for a time an abbé, but afterward became known as the inventor of a skillful and widely used system of stenography. With his brother Gustave, he published a textbook in exposition of this method (4th ed., 1867). Consult the article by Meyer in No. 436 of the *Archiv für Stenographie* (Berlin, 1885).

DUPONCEAU, dū'pōn'sō', PETER STEPHEN (1760-1844). An American writer and scholar. He was born at Saint-Martin, Île de Ré, France, studied law at the college at Bressuire, and became secretary to Baron Steuben, with whom in 1777 he came to America and entered the Continental army, in which he was commissioned a captain, serving with Steuben in the New Jersey and Pennsylvania campaigns and in the South. He left the army in 1781 and became a translator and correspondent in the office of the Secretary for Foreign Affairs, Robert R. Livingston. He remained in that position until the end of the war, when he settled in Philadelphia, where he began the practice of law in 1785 and attained high rank as an advocate. After the purchase of Louisiana President Jefferson offered him the appointment of Chief Justice of the Territory, but he declined. In addition to original legal treatises and translations of French and German legal works, Duponceau devoted himself to philology. Among his published works are: *English Phonology* (1818); *Exposition sommaire de la constitution des États-Unis d'Amérique* (1837); *Mémoire sur le système grammatical des langages de quelques nations indiennes de l'Amérique du Nord* (1838), which won for him a medal from the French Institute; *Dissertation on the Nature and Character of the Chinese System of Writing* (1838).

DU PONT, HENRY ALGERNON (1838-). An American soldier and legislator, born near Wilmington, Del. After graduating from the United States Military Academy in 1861, he served through the Civil War, taking part in the battles of New Market, Piedmont, Lynchburg, Opequan, Fisher's Hill, and Cedar Creek, and being brevetted lieutenant colonel in 1864. He resigned from the army in 1875. Du Pont was the opponent of John Edward Addicks (q.v.) in a famous struggle in Delaware for a seat in the United States Senate, a struggle which lasted nearly 20 years and resulted in several deadlocks. The contest finally ended with the election of Du Pont in 1906; in 1911 he was reelected for the term ending 1917.

DUPONT, du'pôn', PIERRE (1821-70). A French song writer. He was born in Lyons, the son of a workman, was brought up by his cousin, who was priest of Roche Taillière-sur-Saône; studied in the seminary of Largentières, and afterward passed a short time in a lawyer's office. His poem *Les deux* printed in 1842 and won a prize in Dupont afterward wrote some republican verses that came near causing his banishment. He owes his popularity to the songs written for the peasants, such as *Les bœufs*, *Les lapins*, and *Le chanson du pain*. Collections of his songs published include *Chants et chansons* (3 vols., 1852-54) and *Chants et poésies* (7th ed., 1862). Consult Dechant, *Biographie de Pierre Dupont* (1871).

DU PONT, SAMUEL FRANCIS (1803-65). A United States naval officer. He was born at Bergen Point, N. J., entered the navy in 1815, and in 1845 had been promoted to the rank of commander. In the Mexican War, as commander of the *Cyane*, he captured San Diego and La Paz, Cal.; served under Commodore Shubrick in the capture of Mazatlan; and, at the head of a naval force, defeated a large body of Mexicans at San José. In 1855 he was promoted to be captain and in December, 1860, was placed in command of the Philadelphia Navy Yard. In June, 1861, he became president of a board of naval officers appointed to formulate a plan of naval operations against the Confederates, and in September was appointed to the command of the South Atlantic squadron, which in a series of brilliant operations captured Port Royal, S. C., St. Mary's, Fernandina, Jacksonville, Fort Clinch, and St. For this he received the thanks of Congress and was raised to the rank of rear admiral (July 16, 1862). On April 7, 1863, as commander of nine armored vessels, he made a determined attack upon Charleston, S. C., but was repulsed with considerable loss. Admiral Du Pont was relieved by Admiral Dahlgren in July of that year and took no further part in the war. For his services during the Civil War, consult Ammen, *The Atlantic Coast* (New York, 1883).

DUPONT DE L'ETANG, du'pôn' de là'tân', PIERRE ANTOINE, COUNT (1765-1840). A French general, born at Chabanais. His services in the Northern army the wars of the Revolution won mention and brought him promotion. He participated in the overthrow of the Directory and served with great distinction at Marengo, Jena, and Friedland, but his unsuccessful expedition to Spain in 1808, where at Baylen he was compelled to surrender his army, brought about his disgrace and imprisonment. After Napoleon's downfall he was Minister of War during the Hundred Days, and during the second restoration became a member of the Privy Council. Consult Titeux, *Le général Dupont* (Paris, 1903).

DUPONT DE L'EURE, de lër, JACQUES CHARLES (1767-1855). A French statesman, born at Neubourg, Normandy. He was an advocate before the Parliament of Normandy in 1789 and held various judicial offices during the Revolution. He entered political life as a member of the Council of Five Hundred in 1798. He was chosen a deputy from the Eure to the Corps Législatif in 1813 and in the fol-

lowing year was elected to the Chamber of Deputies, by which he was chosen vice president. Re-elected in 1815, he was the author of the famous declaration of the Chamber to the Allies, that France would recognize no government that would not guarantee to it the liberties which had been established by the Revolution. From 1817 to 1848 he was a member of the Chamber of Deputies, acting consistently with the Liberal opposition. In 1830 for a few months he held the portfolio of Justice in the first cabinet of Louis Philippe. After his resignation he continued as a leader of the opposition until the revolution of 1848, when he was chosen President of the provisional government. He retired to private life in the following year. In all his long career his probity and disinterestedness were never questioned, and his sterling honesty and consistent advocacy of constitutional liberty won for him the title of the "Aristides of the French tribune."

DUPONT DE NEMOURS, du'pôn' de nemōūr', PIERRE SAMUEL (1739-1817). A French statesman and writer on finance and an exponent of the theories of the physiocrats (q.v.). He was born and educated in Paris. In 1772 he was Secretary of the Council of Public Instruction in Poland. He went back to France two years afterward to assist his friend Turgot in the administration, and with Turgot went into retirement in 1776. In 1782 Vergennes intrusted him with the task of drafting the treaty dependence of the United he was a member of the Council of State and Commissary General of Commerce. During the Revolution he favored a constitutional monarchy, but was compelled to hide when the Republicans triumphed. He was found and imprisoned, but Robespierre's fall saved him. His reactionary attitude in the Council of Ancients made him exceedingly unpopular and caused him to emigrate to the United States in 1799. He returned to France in 1802, but declined all political office, except that of a commissioner to arrange the transfer of Louisiana to the United States. Jefferson requested Dupont to prepare a scheme of national education. The scheme was never adopted in the United States, but some of its features were embodied in the French code. After Napoleon's first downfall Dupont became secretary to the provisional government, and on the restoration of the Bourbons was made a counselor of state. The return of Napoleon caused him to leave France, and he spent the remainder of his life with his two sons, powder manufacturers, in the State of Delaware. Dupont de Nemours was the author of several tracts on political and economic matters. Consult Schelle, *Dupont de Nemours et l'école physiocratique* (Paris, 1888).

DU PONT POWDER. See EXPLOSIVES.

DÜPPEL, düp'pel, or DY in the Prussian Province of situated on the peninsula miles northeast of Plönburg. Engagements took place here between the Danes and Germans in May and June, 1848, in which the latter were repulsed; but on April 13, 1849, the Germans stormed the place. In the second Schleswig-Holstein War the lines of Düppel were carried by the Prussians, April 18, 1864. Pop., 600. Consult R. Neumann, *Ueber den Angriff der*

duppeler Schanzen in der Zeit von 15 März bis 18 April, 1864 (Berlin, 1865).

DU PRAT, du'pra', ANTOINE (1463-1535). A chancellor of France, born at Issoire (Auvergne). He became President of the Parlement of Paris under Louis XII, and Francis I, on his accession to the throne in 1515, appointed him Chancellor. As such he entered into negotiations with Pope Leo X regarding the abrogation of the Pragmatic Sanction and concluded the concordat by which both the church and the nobility of France were entirely subject to the royal authority. In concluding this agreement he encountered great opposition, chiefly on the part of the clergy and the university, but retained the royal patronage, by which he ultimately secured the archbishopric of Sens and the cardinalate. He advanced the absolute power of the state and has therefore justly been called the predecessor of Richelieu and Mazarin. It is said that he might have been the successor of Pope Clement VII but for the influence of Francis I, who desired to retain his services. Consult Marquis Du Prat, *Vie d'Antoine Du Prat* (Paris, 1857).

DUPRÉ, du'prá', GIOVANNI (1817-82). An Italian sculptor of French descent. He was born at Siena March 1, 1817, and first practiced wood carving at Florence, which he made his home. Although almost entirely self-taught, he won the first prize for sculpture at the Florentine Academy in 1840. Dupré began as a naturalist, but later he learned from Bartolini and others the doctrine of purism, which interfered with the free development of his art. He first gained celebrity with the beautiful recumbent figure of "Abel" (1842, St. Petersburg; replica in Pitti Palace, Florence), but its companion piece, "Cain" (1845, Pitti Palace), was a comparative failure. These were followed by the pedestal for a colossal vase (also in the Pitti), and an unsuccessful design for the monument to the Duke of Wellington. Both show his taste for allegory, which was later developed to excess. His next important work was the bas-relief over the main door of the church of Santa Croce, representing the "Triumph of the Cross" (1862), and the same year he began his masterpiece, the "Pietà," in the campo santo of Siena, a work of remarkable beauty of expression and harmony of lines and planes. For this group he was awarded the gold medal at the Paris Exposition of 1867. In 1868 he was made corresponding member of the French Institute. Other statues by him include the "Despairing Sappho," "Cicero" in the portico of the Uffizi, and "St. Francis" in Assisi. He was not fitted for imposing conceptions and seriously damaged his reputation by the monument to Cavour in Turin (1866-73), his last important undertaking. Dupré's work is forcible, and his anatomy and drapery admirable, but in portrait sculpture he shows lack of individuality and personality. His autobiography, *Pensieri sull' arte e ricordi autobiografici*, appeared in 1879 (trans. by Peruzzi, 1884). Consult Frieze, *Giovanni Dupré* (London, 1886), and Venturi, *Scritti minori e lettere di Giovanni Dupré, con un appendice ai ricordi autobiografici* (Florence, 1885).

DUPRÉ, JULES (1812-89). A French landscape painter of the Barbizon group. He was born at Nantes, April 5, 1812. His father was a porcelain manufacturer at Parmain and afterward in Limousin, and the lad's first experience in design was gained in decorating porcelain

in his father's factory. Some sketches which he made in Limousin attracted the attention of amateurs, and Jules was enabled to go to Paris. He was little influenced by his official teachers, much more by the paintings of Hobbema and Ruysdael, in the Louvre, and always sought inspiration in Nature herself. He was profoundly impressed by the pictures of the Barbizon painters, attaching himself especially to Rousseau, who became his fast friend and greatly influenced his art. In the memorable Salon of 1831 he exhibited fine studies from nature made in Haute Vienne, among which were "Interior of a Forest," "View of Isle Adam," and "Interior of a Courtyard." They attracted great attention, as did his exhibits of 1833: "Evening," "Environs of Paris," and the "Valley of Montmorency." In 1834 he painted his famous "Farmyard," and, at the invitation of Lord Graves, one of his patrons, he visited England in the same year. He was greatly impressed with the English landscapists, especially by Constable, whose work much influenced him. One of the results of this trip was his picture, "Environs of Southampton," exhibited in 1835, a wonderful representation of a storm sweeping across an undulating country. In the same year he exhibited a "Wood in Creuse" and "Pasture in Limousin." In the latter picture he has accomplished the difficult task of . . . effect of a hot summer's day, with . . . contrasts of bright colors just after a rain.

In 1852 he exhibited "Sunset," "Pastureland," and "Entrance to a Village," all excellent works. He did not again exhibit until the Paris Exposition of 1867, to which he sent 12 canvases, including the "Forest of Compiègne," the "Gorge of Eaux Chaudes," and "Pastures of Berry." During the War of 1870 he resided at Cayeux-sur-Mer and found in its barren and lonely neighborhood subjects which well expressed his own melancholy. The marines which he painted at this time, like his "Moonlight," belong to his best work. After the war fortune began to smile upon him, and in 1872 he was able to buy his now historic house at L'Isle Adam. He passed the rest of his life surrounded by his pupils and friends, to whom he communicated his ideas on art in an original fashion. In the Exposition of 1889 there were exhibited, besides his older works, eight others which showed his vigor unimpaired, such as a "Road in the Park of Stors," a "Storm at Sea," a "Ravine in Marais." He died at L'Isle Adam, Oct. 6, 1889—a beautiful and unselfish character, loved by all with whom he associated. The Louvre possesses 16 of his paintings, and American museums, both public and private, are rich in his works. The Metropolitan Museum, New York, possesses excellent examples—the "Old Oak," "Hay Wagon," and a landscape, "Summer"—and the Vanderbilt collection, now on exhibition there, is even richer; its "Midday" is one of his best works. In the Walters Gallery, Baltimore, there are "A Bright Day," "The Old Oak," "Sunset on the Coast," and "At Sea."

Dupré was one of the greatest painters of the Barbizon school—the dramatist of the group, as Rousseau was the lyric poet. He was a melancholy person and loved to portray the tragic, the gloomy, the terrible in nature. He attached especial importance to the handling of light in a picture, and, in order to accomplish this, he often made such free use of impasto that his pictures almost became

reliefs. His colors have been well said that "he sees a prism." But they are harmonious, and he excels in his contrasts. He was made chevalier of the Legion of Honor in 1849, officier in 1870, and received the grand cross of honor at the Exposition of 1889. *Claretie, Peintres et sculpteurs contemporains*, deuxième série (Paris, 1899); Hustin, "Jules Dupré," in *Les artistes célèbres*; *Les hommes du jour: M. Jules Dupré, par un critique d'art* (Paris, 1879); and the articles by Ménard, in *L'Art* (1879), and by Michel (ib., 1883), and the works cited under BARBIZON, THE PAINTERS OF. For his engravings, consult Delteil, *Le peintre-graveur illustré*, vol. i (Paris, 1906).

DUPRÉ, JULIEN (1851-1910). A French painter, born in Paris. He studied under Pils and Henri Lehmann. He renders with robust spirit the simple scenes of country life and is noted for his painting of animals, particularly of cows, and his fresh, brilliant landscapes. In the Luxembourg are his "Mowers of Lucerne" and "White Cow." At the St. Louis Exposition (1904) he exhibited "The Return of the Herd," one of his best works, "Evening," and "Near a Pool."

DUPUIS, du'pwé', CHARLES FRANÇOIS (1742-1809). A distinguished French savant, the son of a poor schoolmaster. He was born at Trie-Château, near Chaumont, and obtained admission into the College of Harcourt, where he so soon acquired extensive knowledge that at the age of 24 he was made professor of rhetoric in the College of Lisieux. At the same time he went through a course of law studies and was admitted an advocate of the Parliament. His acquaintance with Lalande introduced him to the study of mathematics and astronomy, and he was led to the thought of explaining mythology by means of astronomy. After several communications in the *Journal des Savants*, appeared his *Mémoire sur l'origine des constellations et sur l'explication de la fable par le moyen de l'astronomie* (1781). He was now appointed professor of Latin oratory in the Collège de France, member of the Académie des Inscriptions (1788), and shortly after a member of the Commission of Public Instruction. During the Revolution he became a member of the Convention, next of the Council of Five Hundred, and, after the eighteenth Brumaire, of the legislative body. He was also one of the 48 individuals who formed the nucleus of the Institut National. His great work, *L'Origine de tous les cultes, ou religion universelle* (1795), which he had long withheld from fear of offending the religious world, was at last published at the instance of the Cordeliers' Club. This circumstance rendered the book more an object of party bitterness than its own purely scientific character would probably have called forth. It made a considerable impression on France at the time and no doubt afterward caused Napoleon to appoint the famous commission to explore Upper Egypt, which Dupuis had pointed out as the general source of southern mythology. No less attention was awakened by his memoirs on the origin and spread of the Pelasgi and on the zodiac of Denderah (q.v.). In his last work, *Mémoire explicatif du zodiaque chronologique et mythologique* (1806), he attempts to demonstrate the unity of the astronomical and religious myths of all nations.

DUPUIS, NATHAN FELLOWES (1836-).

A Canadian educator and author, born at Portland, Ontario. He graduated in 1866 at Queen's University (Kingston) and in 1867 was appointed professor of chemistry in that institution. In 1880 he was transferred to the professorship of mathematics. He was for a number of years public inspector of schools for Kingston. His publications include: *Elements of Geometrical Optics* (1868); *Junior Algebra* (1882); *Elements of Synthetic Solid Geometry* (1893); *Elements of Trigonometry for Practical Science Students* (1902); *Spherical Trigonometry and Astronomy* (1906); *Descriptive and Mechanical Astronomy* (1910).

DUPUY, C. ALEXANDER (1851-). A French premier, born at Le Puy (Haute-Loire), France, and educated at the Lycée de Le Puy and the Lycée Charlemagne at Paris. He was professor of philosophy at the colleges at Nantua and Aurillac, taught in several lycées, and was later a school inspector for the academies of Lozère and Calvados and vice rector of the Corsican College at Ajaccio. Entering politics, he became a deputy for Haute-Loire in 1885, was reelected in 1889, was Minister of Public Instruction in 1892, and President of the Chamber of Deputies in 1893. He served twice as Premier and Minister of the Interior (1893-95 and 1898-99). In 1900 he became senator for Haute-Loire. He published *Livret de morale* (1891).

DUPUY, JEAN (1844-). A French politician, journalist, and administrator, born at Saint-Palais, Gironde. He became proprietor of the *Siècle* (1886) and of the *Petit Parisien* (1888) and then president of the Paris press syndicate. Elected to the Senate as a radical Republican in 1891, he took a prominent part in debates on finance and agriculture. He was Minister of Agriculture in Waldeck-Rousseau's cabinet in 1899-1902, of Commerce in Briand's (July, 1909-February, 1911) and of Public Works from January to March, 1913.

DUPUY DE LÔME, du'pwé', de lôm, STANISLAS CHARLES HENRI LAURENT (1816-85). A French naval engineer. He was born at Ploemeur, near Lorient, and was educated at the Ecole Polytechnique in Paris, and in England. In 1857 he was chief of department in the Ministry of the Navy and was subsequently appointed director of naval construction. The *Napoléon*, the first iron steamship constructed in France, was modeled upon the principles laid down in his *Mémoire sur la construction des bâtiments en fer* (1844). The first French screw steamships and the first armored vessels, *La Gloire*, *Invincible*, and *Normandie* (1859), also were built in accordance with his instructions. During his reign of Paris he was a member of the Scientific Commission and in this capacity gave advice which sent out more than 100 balloons from the city before the capitulation. In 1872 he demonstrated the possibility of constructing dirigible balloons. He was a deputy in 1869 and senator for life in 1877. See ARMOR PLATE.

DUPUYTREN, du'pwé'trân', GUILLAUME, BARON (1777-1835). An eminent French surgeon and anatomist. He was born at Pierre-Buffière, in Limousin, was educated at the Collège de la Marche in Paris, and on the formation of a new school of medicine there in 1794, was appointed to the office of prosector. In 1812 he became professor of surgery and in 1815 chief surgeon to the Hôtel-Dieu. Louis

XVIII conferred on him the title of Baron, and appointed him royal surgeon in 1823. Dupuytren was a remarkable anatomist as well as a bold and skillful operator. He made several important discoveries in pathological anatomy, and, although he wrote little, he formed a large school of enlightened surgeons in his native country. Among his works may be mentioned: *Leçons orales de clinique chirurgicale faites à l'Hôtel-Dieu* (1830-34); *Traité théorique et pratique des blessures par armes de guerre* (1834); *Mémoire sur une nouvelle manière de pratiquer l'opération de la pierre* (1836).

DUQUESNE, dōō-kān'. A borough in Allegheny Co., Pa., 12 miles north of Pittsburgh, on the Monongahela River, and on the Pennsylvania Railroad. It has a Carnegie library and institute. Its steel works and blast furnaces are extensive. Settled in 1885, Duquesne was incorporated in 1891. Under the charter of that date the government is vested in a burgess, elected every three years, and a borough council. The water works are owned and operated by the city. Pop., 1900, 9036; 1910, 15,727; 1920 (U. S. est.), 18,576.

DUQUESNE, dū'kān', ABRAHAM, MARQUIS (1610-88). One of the most eminent naval officers of France. He was born at Dieppe and was trained for the naval service. Under Louis XIII he distinguished himself in the war against Spain. During the minority of Louis XIV he entered the service of Sweden. Duquesne defeated the Danish fleet near Gothenburg in 1643, was elevated to the rank of vice admiral, and, by a succession of victories over the united fleets of Denmark and Holland, forced Denmark to conclude peace. When the Spaniards prepared to support Bordeaux, which had declared itself for the party of the Fronde in 1650, he collected a squadron at his own expense and compelled Bordeaux to submit. On the revolt of Messina against the Spanish government France sent him to support the insurgents. With a small force Duquesne gallantly opposed the united fleets of Spain and Holland, commanded by De Ruyter, and in April, 1676, completely defeated his enemies off the coast of Sicily. In 1682 Duquesne cleared the Mediterranean of the Barbary pirates, and in 1684 he bombarded Genoa. Louis XIV rewarded Duquesne with the title of marquis and a considerable estate. On the revocation of the Edict of Nantes Duquesne was excepted from the general decree of banishment issued against all Protestants. Consult Plon, *Duquesne et la marine de son temps* (Paris, 1872).

DUQUESNOY, dū'kā'nwā', FRANÇOIS (1594-1643). A Flemish sculptor, born in Brussels. He studied under his father, who was a sculptor, and then in Italy, where most of his work was done. The details of his life are uncertain, but he seems, after a long and hard struggle, to have made a name for himself, but scarcely a living, though he acquired the friendship of Van Dyck, Poussin, and Albano, and the patronage of Constable, Filippo Colonna, Marquis Giustiniani, and Pope Urban VIII. For the latter he modeled the groups of children for the columns of the high altar in St. Peter's, Rome, a statue of St. Andrew in the same church, and a statue of St. Susanna for Santa Maria di Loreto, Rome. Finally Cardinal Richelieu, who had heard of Duquesnoy through Poussin, invited him to the court of Louis XIII; but on his way to France the artist died at Livorno. poisoned, it is said, by his brother Jérôme.

Duquesnoy is best known for his naïvely naturalistic representations of children, and especially for his graceful and charming reliefs, of which the most popular represent children with a goat, the drunken Silenus, or Bacchus. Beautiful examples of such reliefs in ivory, in which medium Duquesnoy excelled, are in the Museum of Dresden and in the South Kensington Museum, London. The celebrated Manikin Fountain in Brussels is usually attributed to him.

DUQUOIN'. A city in Perry Co., Ill., 74 miles southeast of East St. Louis, on the Illinois Central Railroad (Map: Illinois, C 6). It has ironworks, planing mills, flour mills, and extensive coal mines. Under a charter of 1873 its government is vested in a mayor, elected biennially, and a unicameral council of 10 members. Pop., 1900, 4353; 1910, 5454.

DURA DEN, dōō'rā dēn. A small glen between Cupar and St. Andrews, in Fifeshire, Scotland, through which runs a tributary of the Eden, geologically famous on account of the numerous and beautifully preserved fossil fish entombed in its yellow sandstone.

DUR'A MA'TER. See NERVOUS SYSTEM.

DURAMEN (Lat., hardness, from *durus*, hard). A term applied by botanists to the inner, more solid, and usually darker heartwood of conifers and dicotyledons. The dark-colored duramen of some trees, of which a good example is the ebony, is of considerable importance in cabinetmaking, while the light-colored sapwood or "alburnum" of these same trees is of little value. See WOOD.

DURÁN, dōō-rān'. AGUSTÍN (1789-1862). A Spanish poet and critic, born in Madrid. After a prolonged course of profound studies in the humanities, he was educated for the law in the University of Seville and admitted as an advocate. In 1834, during the parlous times of the regency of Queen Christina and the outbreak of the first Carlist War, he was secretary of the board for the censorship of the press, and soon afterward had a place in the National Library, of which he became director in 1854, retiring in 1855 to devote himself to his literary work. Despite his poetic ability as shown by his poem *Leyenda de las tres toronjas del vergel de amor* (1856) he is best remembered as a creative, or constructive, literary critic. In 1828 he published anonymously a *Discurso sobre el influjo que ha tenido la critica moderna en la decadencia del teatro antiguo*, a treatise which greatly influenced the younger dramatists of the period. He did also a great deal of very valuable work for the collection and preservation of the ballad literature of Spain, of which he published 5 vols. (1828-32), which were republished, with important additions and notes, in 2 vols. (*Biblioteca de autores españoles*, vols. x and xvi, Madrid, 1849-51). In 1839 he was elected a member of the Real Academia Española, and his name appears in its official *Catálogo de autoridades de la lengua*.

DURAN, dū'rān', CHARLES AUGUSTE EMILE DURAND, usually called CAROLUS-DURAN (1838-1904). A French portrait painter. He was born at Lille, July 4, 1838, and studied under Souçon at the Lille Academy of Art and afterward at the Ecole Suisse in Paris, where he devoted himself chiefly to copying the old masters in the Louvre, especially Leonardo and Velasquez. In 1861 he obtained the Vicar prize for painting and went to Italy and Spain, continuing his

study of Velazquez, who remained his chief model. While at the monastery of St. Francis near Subiaco, during his stay in Rome, he painted his first important work, "The Evening Prayer" (1863). This was followed by "The Assassination" (1866, in the Lille Museum), a picture which shows much dramatic power. After his journey to Spain he turned his attention to portraiture and exhibited "The Lady with the Glove" (1869), a full-length portrait of his wife in outdoor costume, one of his best works and now in the Luxembourg. This was followed by a series of brilliant portraits. In 1873 he opened an atelier, and many Americans sought his instruction. Among his pupils were Low, Sargent, and others. His portraits are usually of women and children. They are essentially modern, lifelike, and boldly painted. But while his early pictures show great strength and nobility of color and admirable handling of drapery, in later years his art declined. In technique Duran has rarely been surpassed, but in interpretation of personality his great pupil, Sargent, goes beyond him, and Duran never nearly equals his chosen master, Velazquez, in subtlety of expression. His other works include portraits of Monsieur Edouard R. and Madame Feydeau; "Lady with a Dog" (Lille Museum); "At the Seaside"; an equestrian portrait of the actress Mademoiselle Croizette; "Bettina," very much like Velazquez in treatment; the Countess of Vandal; Madame de Pourtalès, Emile de Girardin, Gustave Doré, Gounod, Pasteur, and the painter François (1900), now in the Luxembourg. He also painted landscapes, such as "Evening on the Loire" in the Luxembourg, and a series of historical and genre subjects, in which the influence of Veronese and Rubens is apparent. Among these are the "Bathers"; the "Gloria Mariæ Medici," a decorative composition for a ceiling in the Louvre; the "Burial of Christ" (1882); "Dawn"; and the "Vision." He received the medal of honor in 1879. In 1890 he helped to found the Société Nationale des Beaux-Arts, and in 1900 he was made president of this association and grand officer of the Legion of Honor. At St. Louis in 1904 he exhibited a portrait of Madame Jaques Stern, "Christ's Last Hour," and "A Thunder Storm." In 1905 he was named member of the Institute and director of the French Academy at Rome. Consult Muther, *History of Modern Painting* (New York, 1907), and his biography by Alexandre (Paris, 1902).

DURANCE, du'rāns'. A river in the southeastern part of France, rising in the Department of Hautes-Alpes, near the base of Mont Genève (Map: France, S., L 4). It flows through the Department of Basses-Alpes in a southerly direction, then, curving westward, proceeds towards the Rhône, forming the boundary between the departments of Vaucluse and Bouches-du-Rhône, and joins the Rhône about 3 miles below Avignon. Its total course is about 225 miles—no part of which is navigable. It supplies Marseilles with water by an aqueduct, 51 miles in length, and irrigates an otherwise arid region.

DURAND, du'rān', ALICE MARIE CÉLESTE. See GRÉVILLE, HENRY.

DURAND, ASHER BROWN (1796-1886). An American painter and engraver, born at South Orange, N. J. In early life he was apprenticed to the engraver Maverick, with whom he later entered into partnership. Two of his well-known plates are those after Trumbull's "Declaration

of Independence," and "Ariadne," after Vanderlyn. They are clear and strong in line and faithful in the reproduction of his models. In 1835 he began as a portrait painter. His subjects included General Jackson, Henry Clay, and heads of all the presidents, done from nature or copied. In figure pieces, such as "The Wrath of Peter Stuyvesant" (New York Historical Society), he was less successful. From 1841 until his death he devoted himself principally to landscape painting, and with Thomas Cole founded the American landscape school. His landscapes are really large sketches or studies, painted directly from nature, which was unusual in his day. They are somewhat imperfect in composition and hard in color, but good in line and interesting in detail. His "Mountain Forest" (1869) is in the Corcoran Gallery at Washington, and the Metropolitan Museum possesses four of his works, including "In the Woods," one of his best landscapes. Another good example is in the New York Public Library. He was one of the original members and president of the National Academy of Design (1845-61). Consult his biography by John Durand (New York, 1894), and Isham, *The History of American Painting* (ib., 1905).

DURAND, E(DWARD) DANA (1871-). An American statistician, born at Romeo, Mich., and educated at Oberlin. He graduated in 1893, and at Cornell in 1895 and 1902 he was legislative librarian of the New York State Library, assistant professor of administration and finance at Leland Stanford Junior University, instructor in economics at Harvard University, secretary of the United States Industrial Commission, and special expert on street railways and electric-light plants for the United States Census Office. He was special examiner for the Bureau of Corporations (1903-07); deputy corporation commissioner (1907-09); director of the Census to 1913, and afterward professor of statistics at the University of Minnesota. In 1910 he was elected a vice president of the American Statistical Association. Besides contributions to economic journals, he is author of *Finances of New York City* (1898).

DURAND, ELIAS (1794-1873). An American botanist, born at Mainz, Germany. He pursued medical studies and became a member of the medical corps of the French army. Upon the fall of the First Empire he emigrated to the United States and set up a drug store in Philadelphia. He collected an herbarium which included no less than 10,000 species of North American flora, and which he presented to the Museum of the Jardin des Plantes, Paris, where a special gallery was assigned to it.

DURAND, WILLIAM FREDERICK (1859-). An American marine engineer, born at Bethany, Conn. He graduated at the United States Naval Academy in 1880 and was a member of the United States Naval Engineer Corps in 1880-87 and professor of mechanical engineering in the Agricultural and Mechanical College of Michigan in 1887-91. In 1891 he became professor of marine engineering in Cornell University, and in 1904 he went to Leland Stanford Junior University as professor of mechanical engineering. Besides contributions to engineering journals, he published: *Fundamental Principles of Mechanics* (1889); *The Resistance and Propulsion of Ships* (1895); *Practical Marine Engineering* (1901); *Motor Boats* (1907).

DURANDANA, duō'rān-dā'nā, also DURAN-

DAL, DURENDA, DURINDANA. Roland's sword, which he broke in two on the day of his death, lest it should fall into cowardly hands.

DURANDARTE, dūr'ān-dar'tā. A traditional Spanish hero, killed in the battle of Roncesvalles. He is mentioned in the old ballads and appears in *Don Quixote*.

DURAND-CLAYE, dūr'ān'klā', ALFRED AUGUSTIN (1841-88). A French engineer. He was born in Paris, where he was chief engineer of the Department of Public Sanitation and professor of hydraulic agriculture at the Ecole Nationale des Ponts et Chaussées and at the Ecole des Beaux-Arts. He subsequently became inspector general of roads and bridges. The following are his more important works: "Stabilité des voûtes en maçonnerie," in the *Annales des Ponts et Chaussées* (1867), a work which was extensively used in civil engineering schools; *Stabilité des arcs métalliques*; *Assainissement de Bruxelles* (1870); *Pompes centrifuges* (1873); *Lac Fucino* (1878); *Assainissement de Paris* (1884); *Cours d'hydraulique agricole* (1890).

DURANDUS, GULIELMUS, also known as GUILLAUME DURAND, DURANTI, or DURANTIS (1237-96). A Roman Catholic prelate and jurist, surnamed the Speculator. He was born at Puimisson, near Béziers, and was educated at Bologna. After teaching canon law at Modena and occupying several important offices in the papal service at Rome, he was appointed Bishop of Mende in Languedoc (1286), whence he was recalled to Italy in 1295 by Pope Boniface VIII, who appointed him Governor of Romagna. A splendid tomb was erected to his memory in the Dominican church of Santa Maria sopra Minerva at Rome. The principal work of Durandus is the *Speculum Judiciale* (c.1271), a complete system of practical jurisprudence, comprising for the first time all the Roman and ecclesiastical laws. The work is based upon a careful study of the legislative texts, the jurisprudence, and the commentaries of previous writers, and is valuable both from a historical and a practical point of view. More than 40 editions of it have been published, the best being that of 1612. The liturgical work of Durandus, *Rationale Divinorum Officiorum*, was translated into English by J. M. Neale and B. Webb under the title *The Symbolism of Churches and Church Ornaments* (1843; 3d ed., 1906). As the *Speculum* was basic in its influence upon the development of legal procedure, so the *Rationale* may be accepted as the standard work on the liturgy of the Roman Catholic church. It was published at Mainz in 1459 and is one of the first specimens of the art of printing.

DURANGO, dūr'āngō, known also as Ciudad de Victoria and formerly as Guadiana). A city, the capital of the State of Durango, Mexico, 480 miles north by west of Mexico City, on the Funal River and on the Mexican International Railway (Map: Mexico, G 5). It is situated 1927 meters (6321 feet) above sea level, in a valley near the famous iron-ore hill, Cerro del Mercado. The city is an episcopal see and contains a handsome cathedral. Other imposing buildings include the government palace, city hall, theatre, and hospital. It formerly had a mint, which dated from 1811 and coined annually gold and silver to the amount of about \$1,000,000. There are a college, formerly controlled by the Jesuits, an episcopal seminary, a public library, a penitentiary,

and a bull ring. The city is lighted by electricity, and has street railways and telephone service. Durango is in an agricultural and stock-raising district and is an important mining centre, it has also cotton and woolen mills, flour mills, sugar-cane mills, foundries, and a large tobacco factory. It is the leading commercial city of the state. There are thermal and mineral springs in the vicinity. Durango was founded about 1560 by Alonzo de Pacheco. It was the capital of the Province of Nueva Vizcaya, which included (until 1823) Durango and Chihuahua. Pop., 1895, 26,428; 1900, 31,092; 1910, 34,085.

DURANGO. An inland state of Mexico, bounded on the north by Chihuahua, on the east and southeast by Coahuila and Zacatecas, and on the west and southwest by Sinaloa and touching Tepic on the south (Map: Mexico, F and G 5). Area, 38,009 square miles. Durango is 5,000 feet high, semiarid plateau, with the Rio Grande Madre traversing its western portion. There are no large rivers in the state. The soil of the plateau is generally of good quality and with irrigation could be made productive. Wheat and vegetables are successfully cultivated in some districts, and sugar cane and cotton in the valleys. Some corn, tobacco, and grapes are also produced. The climate is dry and healthful, but hot on the western slope of the Sierra. In the mountain valleys stock-raising is an important industry. Durango's principal source of wealth is mining, and the region has been famous since colonial times for its output of silver. Some of the ore assays very high, that of the Candelaria Mine between \$70 and \$140 a ton. This mine, in the San Dimas District, west of the Sierra, is said to have produced over \$100,000,000 before the end of the nineteenth century. In the fiscal year 1911-12 the silver output of the state destined for exportation was 120,657.6 kilos, valued at \$59,928,000. The gold output was \$59,928,000, valued at 1,146,528 pesos.

Copper, iron, cinnabar, zinc, and lead occur; but the mining of base metals has not been extensively developed on account of inadequate transportation facilities. A short distance south of Durango City is the Cerro del Mercado, a hill of high grade iron ore estimated to contain several hundred million tons of the metal. The hill is about 640 feet high (above the surrounding country), 1100 feet broad, and 4800 feet long. In its vicinity are iron and steel works. The mines are controlled chiefly by American capital. Manufacturing has made some progress since 1900; there are soap and candle factories, tanneries, pottery works, etc. At the end of the fiscal year 1912 six cotton mills were in operation; their consumption was 400,000 kilos, and the value of their output \$99,153 pesos. The state is crossed by the Mexican Central (in the east) and Mexican International railways. Pop., 1895, 292,549; 1900, 370,294; 1910, 483,175. The inhabitants are largely of Indian blood. Of the total in 1910, 88,358 could read and write, 7615 read only, and 224,313 of 12 years and over were illiterate. The population is almost entirely Roman Catholic, 480,328 being returned as of that faith in 1910. The state has only six towns with over 4000 inhabitants: the capital, Durango (34,085); Gómez Palacio (15,997); Ciudad Lerdo (8609); Mapimi (8204); Velardeña (5939); and Ojuela (5086).

DURANGO. A city and the county seat of La Plata Co., Colo., about 300 miles (direct) west by south of Pueblo, on the Las Animas River, and on the Denver and Rio Grande and the Rio Grande Southern railroads (Map: Colorado, B 4). The city has a C. . . library and municipal water works. . . commercial centre for southwestern Colorado and northwestern New Mexico, a region devoted to lead, gold, and silver mining, stock raising, and agriculture. Durango has smelting and reduction works, flouring mills, a packing plant, foundries, and extensive coal and coke interests. The commission form of . . . was adopted in April, 1913. Pop., 1900, 3317; 1910, 4686.

DURANT. A town and the county seat of Bryan Co., Okla., 20 miles north by east of Denison, Tex., on the Missouri, Oklahoma, and Gulf, the Missouri, Kansas, and Texas, and the St. Louis and San Francisco railroads (Map: Oklahoma, E 5). Among its institutions is a Presbyterian college and the Southeastern State Normal school. The chief industry is agriculture, cotton, corn, and berries being the principal products. There are also flour and oil mills. Under a charter of 1904 its government is vested in a mayor and a unicameral council of six members. The water works and electric-lighting plant are owned by the municipality. Pop., 1900, 4510; 1910, 5330.

DURANT, HENRY FOWLE (originally Henry Welles Smith) (1822-81). An American lawyer and philanthropist, born at Hanover, N. H. He graduated at Harvard in 1841, studied law, and subsequently built up a profitable practice in Boston. After a conversion to the evangelical view of religion, which drew widespread attention, he was from 1864 to 1875 a lay preacher in Massachusetts and New Hampshire. He is best known, however, as the founder of Wellesley College (q.v.), to which he contributed between one and two millions of dollars.

DURANTE, dōō-rān'tā, FRANCESCO (1684-1755). An Italian composer, one of the founders of the Neapolitan school of music. He was chapelmaster in Naples, and in 1742 was at the head of the Conservatorio Santa Maria di Loreto in that city. He had great fame as a teacher. Among his pupils were Duni, Jommelli, Piccini, Pignatelli, S. . . and Paisiello. Under Durante the Neapolitan school reached the climax of its celebrity, and it was in this school that the great traditions of Italian vocal art were established. As a composer, he adhered to the severe style of the early Italian masters.

DURANTIS, dū'rān'tās', GULIELMUS. See DURANDUS, GULIELMUS.

DURÃO, dōō-rōun'. JOSÉ DA SANTA RITTA. See SANTA RITTA DURÃO.

DURAS, dū'rās', CLAUDE LECHAT DE KERSAINT, DUCHESS OF (1777-1828). A French novelist, whose *Ourika* (1823) and *Edouard* (1825) represent the best phase of the culture of the Restoration and foreshadow the socialistic fiction of George Sand (q.v.). Consult A. Barjoux *Mon. de Duras* (Paris, 1898).

DURATION (ML. *duratio*, from Lat. *durare*, to last), or PERSISTENCE IN TIME. The simplest temporal determination of mental processes. It may be assumed that every simple conscious process and every state of consciousness has a normal duration, varying with variation of circumstances, but still capable of numerical statement. The ascertainment of this normal

duration is of importance to an exact psychology, and a good deal of work has accordingly been done upon it. Unfortunately the complication of factors is so great, even in the most favorable case—that of sensation—that the results so far obtained must be taken with reserve. Suppose, e.g., that we try to determine the duration of pressure sensation by applying an intermittent stimulation at a chosen point of the cutaneous surface and noting the rapidity at which the stimuli may follow one another without giving rise to a single continuous pressure. If we mark the point at which the stimuli are still just sufficiently separated to give a rough, . . . on, we shall say that the skin . . . pressures of $\frac{1}{10}$ of a second's duration and under. If, on the other hand, we demand that the pressure sensations be full and clear, we shall put their duration as high as $\frac{1}{10}$ or $\frac{1}{8}$ of a second. And these two values will vary, further, with the intensity of the applied stimuli. In the sphere of vision the duration of sensation depends partly upon the intensity of stimulus, partly upon the character of the visual interval which separates the given sensations. Külpe estimates it, omitting the negative after-image (see AFTER-IMAGES), at $\frac{1}{10}$ of a second. Temperature sensations last, on the average, about half a second. The times required for the cognition of tones vary considerably with practice. Maximal practice presupposed, they lie . . . between one and two vibrations and . . . with increase of the pitch number of the stimulus. Thus, a tone of 64 vibrations must be sounded for $\frac{1}{10}$ of a second, while a tone of 187 vibrations can be cognized in $\frac{1}{10}$ of a second. There is, however, a point upon the scale at which the duration of stimulus necessary to the cognition of a tonal quality sinks to an absolute minimum. This point lies at the G of 3168 vibrations in the second, which can be heard if the tone sound only for $\frac{1}{10000}$ of a second. (For the duration of a pulse or wave of attention, see ATTENTION.) No investigation of affective durations has as yet been undertaken.

Psychologists have also made a study of duration as such—i.e., of our capacity to perceive and to compare empty time intervals. Thus, two electric sparks seen in daylight are clearly differentiated if the time between them amount to $\frac{1}{10}$ of a second; the snaps of two sparks are heard as separate, under favorable conditions, if the interval be as small as $\frac{1}{100}$ of a second. When the impressions belong to two different senses . . . (touch-hearing, touch-sight, . . . just noticeable interval varies . . . in which they come (touch-hearing or hearing-touch) and with the direction of attention: the values most frequently obtained fall within the limits $\frac{1}{10}$ and $\frac{1}{8}$ of a second. It need hardly be said that the judgment in these cases is a judgment simply of the separateness of the two sensations, and that the attention is directed upon the stimuli themselves and not upon the length of the time interval between them.

Our appreciation of the relative duration of short intervals—i.e., our judgment as to whether a given interval is longer or shorter than another—is somewhat astonishingly accurate. For psychological purposes intervals fall into three groups: (1) "short" times, ranging from the just noticeable duration to about 0.5 or 0.6 of a second; (2) "moderate"

times, extending from this latter value to 3 or 4 seconds; and (3) "large" times, from 4 seconds upward. In the case of (1) our temporal estimation is direct: the impressions which limit the intervals (sharp sounds) are all in consciousness together, we do not compare the intervals, but judge simply of the rapidity or rate of succession of the limiting stimuli. Our judgment is therefore strongly influenced by the quality, intensity, and duration of these limiting impressions, as well as by their rhythmical form, by the direction of attention, etc. With maximal practice and under favorable conditions, an interval of 0.3 second may be discriminated from an immediately following interval of 0.303 second. In the case of (2) and (3) the temporal estimation is indirect. Large times are judged predominantly in terms, not of time, but of its contents: the greater the number of ideas, perceptions, or feelings in the interval, the longer is the interval estimated to be. Moderate times seem to furnish the material of true temporal comparison. The first limiting impression of the first interval is just disappearing from consciousness as the first impression of the second interval enters. The former impression is then reproduced; a definite direction is given to the strain of attention, and the closing impression of the second interval is "expected" at a moment corresponding to that at which the first interval closed. The basis of judgment is thus given by strain and other organic sensations, with their accompanying feelings.

The work so far accomplished upon the course of temporal discrimination is incomplete, and the laws upon which it rests demand further confirmation. It appears, however, that there is constancy of the relative differential sensitivity (see DISCRIMINATION, SENSIBLE) over a certain range of short and moderate times; that short intervals are overestimated and longer intervals underestimated; and that this error of estimation has the zero value at an interval of 0.5 or 0.6 second (indifference point of temporal discrimination). See BERGSON, HENRI.

DURATION. In plants, the length of the vegetative period. One of the chief ecological classifications is based on the duration of the various plants or their organs. Perhaps the most important classification of this kind is that into monocyclic, dicyclic, and polycyclic plants, or, as they are more popularly called, annuals, biennials, and perennials. Whether or not these types may be regarded as the product of certain ecological conditions, it is certain that they are often associated with particular environments. Annuals and biennials, e.g., are most common in new habitats, as in gardens allowed to run wild, and after fires, or in xerophytic situations, as on shores and deserts. Perennials, on the other hand, comprise most of the world's vegetation and dominate particularly in habitats that are ecologically rich or that have been long established. It seems, therefore, that the perennial habit is, on the

whole, the most successful, and it is not difficult to see why, since perennials commonly spread vegetatively as well as by seed. Each year, therefore, the perennials are on the ground at the beginning of the season, while annuals and biennials are obliged to start from seed. A garden patch allowed to run wild shows, as a consequence, fewer and fewer annuals and more and more perennials each year until finally the annuals are gone. In desert regions and along shores the vegetation is sparse, and annuals or biennials may exist almost indefinitely. Annuals are scarce in Alpine and Arctic regions, perhaps because the vegetation periods are too short for their development.

Another important classification based on duration is that into deciduous and evergreen forms; in these plants, however, the critical point is not fully expressed when these terms are employed. Deciduous forms may be defined as plants which shed their organs, and especially leaves, regularly; whereas evergreens are those plants which shed their leaves irregularly. Evergreen leaves are much longer lived than deciduous leaves. The significance of these types will be discussed under the head of FOREST (q.v.). The duration of stems depends largely on their structural nature; in temperate climates most aerial herbaceous stems are annual, whereas woody stems are perennial. Flowers, in contrast to other organs, have an ephemeral duration. There seems thus to be a harmonious relation between duration and structure, organs with long life having resistant structures, while short-lived organs are commonly delicate. See FOREST; STEM; VEGETATIVE PROPAGATION; BIENNIAL; ANNUAL; PERENNIAL.

DURAZZO, *dōō-rāt'sō* (Turk. *Drasch*, Slav. *Drach*, Albanian *Durësi*, from Lat. *Dyrrhachium*, from Gk. *Δυρράχιον*, from *δυσ-*, *dys-*, bad + *ρῥύναι*, *rhēgnynai*, to break, in allusion to the surf on the peninsula). A decayed maritime town in the Principality of Albania, built on the rocky peninsula of Pelu, in the Adriatic, about 55 miles south of Scutari (Map: Turkey in Europe, B 4). It is surrounded by dilapidated old walls. The town has been the seat of a Catholic archbishop since the days of Justinian. The once fine harbor has been silted up. Durazzo exports to Austria-Hungary olive oil, wool, raw silk, and some grain. Under the Turks the population fell as low as 1200; it is now over 5000.

Durazzo is the ancient Epidamnus, which was founded 625 B.C. by a band of Corcyraeans and Corinthians. Owing to its position on a fine bay, an inlet of the Adriatic Sea, and to the fertile country about it, Epidamnus became a great and populous city, but was much harassed by internal party strifes: the banishment of its aristocratic element in 436 B.C., and the consequent dispute regarding authority between Corcyra and Corinth constituted one of the causes of the Peloponnesian War. It passed to the Romans in 229 B.C. To them the name Epidamnus suggested the noun *damnum*, 'loss,' so that it seemed to signify "Lossville," or the like, hence they employed rather the other name of the city Dyrrhachium. (See Pliny, *Historia Naturalis*, iii, 145; Plautus, *Menæchmi*, 264-265.) It later became the seat of a Roman colony and the regular landing place for those journeying to Greece. (See BRINDISI.) Dyrrhachium was the starting point of the impor-

tant Via Egnatia, a main highway leading to Byzantium and to Asia. Here Pompey was for some time beleaguered by Cæsar; extensive swamps about the city made it easy to defend. About the end of the fourth century it became the capital of the Byzantine Eparchy of New Epirus. The town was taken by the Ostrogoths, Bulgarians, and Normans, and in the latter part of the Middle Ages belonged successively to the house of Anjou (then ruling in Naples) and to Venice, from which it was wrested by the Turks in 1501. See the article "Dyrrachion" (illustrated), in Pauly-Wissowa, *Real-Encyclopædie der klassischen Altertumswissenschaft*, vol. v (Stuttgart, 1905). For four centuries Durazzo remained under Turkish rule as a part of the Vilayet of Scutari; it steadily declined and seemed to lose all importance. The Balkan War of 1912-13 (q.v.), however, brought the ancient town once more into prominence. From the outset of the struggle the Servians made Durazzo the objective of a proposed extension of their kingdom to the Adriatic, and on Nov. 28, 1912, they occupied the town. The determination of Austria-Hungary and Italy to prevent Serbia from securing an outlet on the Adriatic led to grave international complications, which were ended only by the withdrawal of the Servians early in 1913 and the incorporation of Durazzo in the newly erected Principality of Albania. Until the arrival in the country of William of Wied, the first prince of the new state, in 1914, Durazzo was the seat of the provisional government of Essad Pasha.

DURBAN, dër'bān. A seaport town of British South Africa. See **PORT NATAL**.

DURBAR, dër'bār (Pers. *darbār*, audience). A Hindustani word signifying a court or place of judgment in which are decided, or from which are promulgated, affairs of importance to the state or tribe. Throughout India, Afghanistan, and in parts of Persia, it is customary for rulers, governors, or chiefs to give audience to distinguished visitors in "darbar" as well as to ratify treaties or make important agreements. The British Viceroy and all other British governors in India follow the native custom, in accordance with which Queen Victoria was proclaimed Empress at a magnificent durbar held on the ridge at Delhi in 1877, and King Edward VII as Emperor in 1902. The term "darbar" is applied also to the room or place of audience.

DURBIN, JOHN PRICE (1800-76). An American clergyman, born in Bourbon Co., Ky. At 20 years of age he entered the Methodist ministry, but while preaching pursued a course of study, part of the time attending Miami University and in 1825 graduating from Cincinnati College. He was chaplain of the United States Senate in 1831, for two years was professor of languages in Augusta College, Kentucky, edited *The Christian Advocate and Journal* of New York (1832-33), and from 1834 to 1842 was president of Dickinson College. The year 1843 he spent in travel abroad. Much of the success of the Missionary Society of the Methodist Episcopal church is due to his efforts while secretary in 1850-72. Next to Bishop Matthew Simpson, he was considered the most eloquent man of his generation in the denomination. He published *Observations in Europe, principally in France and Great Britain* (2 vols., 1844) and *Observations in the East, chiefly in Palestine, Syria, Egypt, and Asia*

Minor (2 vols., 1845); and he edited Wood's *Mosaic History of Creation* and *The Short Sermons of Jonathan Edmondson*. Consult Roche, *The Life of John Price Durbin* (New York, 1889).

DURCHMUSTERUNG. See **ASTROPHOTOGRAPHY**.

DUR'DEN, DAME. The name of a conscientious housewife in a well-known old English ballad and hence applied as an affectionate nickname to Esther Summerson in Dickens's *Bleak House*.

DÜREN, dü'ren. An ancient town of Rhenish Prussia, situated on the Roer, 18 miles east of Aix-la-Chapelle (Map: Prussia, B 3). Its Gothic church of St. Anna, which is a relic of the saint, attracts many pilgrims. In the museum, built 1905, are collections of antiquities, natural history, and painting, and a public library. The town hall has a fine assembly room. The town manufactures paper, sugar, cloth, wool, cotton, and flat goods, linen, carpets, castings, needles, machinery, and beer. Pop., 1900, 27,171; 1905, 29,770; 1910, 32,511. Here Charles V. was on his way to attack the Saxons, in 1544, and in 775 and 779 A.D. Consult Schoop, *Geschichte der Stadt Düren bis 1544* (Düren, 1901), and *Beschreibung des Begreviers Düren* (Bonn, 1902).

DÜRER, dü'rër, ALBRECHT (1471-1528). A German painter, engraver, and designer of the Franconian school, the most prominent and influential master of the German Renaissance. He was born at Nuremberg, May 21, 1471. His father, a goldsmith, was a native of Eytas, Hungary, who had come to Nuremberg in 1455. There has been much argument whether he was German or Magyar; however this may have been, the son was thoroughly German in character and in art. His mother was Barbara Holper, a native of Nuremberg, and Dürer was the third of a family of 18 children. These facts as well as those of his early years are quaintly narrated in the introduction to the journal which he later wrote. After learning to read and write at school, the lad worked with his father at the goldsmith's trade. His early talent for design is shown in a clever drawing of himself at the age of 13, in the Albertina collection, Vienna, and in a pen drawing of himself with Two Angels" (1485), in the Museum of Berlin. Yielding to his son's desires, his father in 1486 apprenticed him to the painter Wohlgemuth, with whom he studied three years. After Easter, 1490, the young artist began his "Wanderjahre" (the years spent in travel by a German journeyman before he became a master). His journal does not tell us whither his footsteps led him, but we know from other sources that he worked at Colmar (Alsace), in the atelier of Martin Schongauer, who had died shortly before his arrival. He afterward was occupied with wood engraving at Basel, as is known from his signature on certain blocks which still survive, and he probably was at Strassburg in 1494. He appears also to have visited Venice to judge from the Italian influence in his work and from an expression in a letter written 11 years later. After the customary absence of four years he returned to Nuremberg and married Agnes Prey, the daughter of a cultured merchant. She was probably a good wife, and not the Xantippe she was reputed to be, thanks to the pique of Dürer's

ALBERT DÜRER

PORTRAIT OF "HIERONYMUS HOLZSCHUHER," FROM THE PAINTING IN THE NATIONAL GALLERY, BERLIN

friend Pirkheimer. In 1497 Dürer opened a studio of his own at Nuremberg and figured thenceforth as an independent master.

The work executed up to the time of his visit to Venice, in 1505, belongs to his first period. His early work shows little influence of Wohlgenuth, but much of Mantegna and some by Jacopo de' Barbari, a Venetian artist then residing in Nuremberg, who taught him anatomy and ideal proportions. It consisted chiefly of engravings: that wonderful series of woodcuts, the "Apocalypse," so typical of the restless spirit of the age and full of the bold geniality of youth; the greater number of blocks for "The Large Passion" series; and most of "The Life of Mary." He also began his work in line engraving, at first after Italian models, but becoming independent. His works were chiefly altarpieces, designed by himself, but to some extent executed by his pupils, according to the custom of German painters of the day. The earliest is in the Dresden Gallery and represents the "Virgin Adoring the Sleeping Christ Child." Another, the Bamberger altar (Munich), depicts in the central panel the "Nativity," in the wings the figures of two "donors" in knightly armor as Saints George and Eustachius. The recent restoration of these paintings was a remarkable triumph of the modern restorer's skill. In the central panel it resulted in the addition of the tiny figures of seven small donors; in the wings the horses, breastplates and helmets of the knights, together with forest backgrounds, were removed. The best of the religious subjects is the "Adoration of the Magi," painted in 1504 for Frederick the Wise, Elector of Saxony, but now in the Uffizi Gallery at Florence. It is well composed, and enriched by charming landscape, with good perspective. The Virgin is fair-haired and German, and the kings are dignified and well-modeled figures, with fine heads.

The portraits of this period were executed without the assistance of his pupils and are powerful and characteristic. There are two interesting portraits of Dürer's father—one in the Uffizi, executed before his "Wanderjahre," in 1490, and the other in the National Gallery, London, done in 1497. Among the very best of his portraits are two of himself. That of 1498, of which the original is in Madrid (the Florence example being a copy), shows a faultlessly attired youth of noble features, with long fair hair, and having the noble bearing for which he was celebrated. In the more mature, full-face portrait dated 1500 (Munich), the beautiful ringlets are even more luxuriant, and the head is Christlike in its refinement and dignity. According to Wölfflin both the signature and date (1500) are forgeries, the real date being about 1506. Among his other portraits of this period are Frederick the Wise of Saxony (Berlin), two of "Katharine Fülleger" (Frankfurt), of Hans Tucher and his wife (1499, Weimar), of Oswald Krell (1499, Munich), and the so-called Hans Dürer (1500, Munich).

The Venetian journey of 1505 caused a change in Dürer's art. Before this time his work was angular and stiff, like that of the German school. The study of the antique and of the works of Venetian masters refined his sense of form and gave him a larger view of art, but he never lost his individuality. He was especially influenced by Giovanni Bellini, whom he considered the

greatest of painters and who proved a good friend. The other Venetian painters viewed him with curiosity and envy, but the nobility honored him, and before he left Venice the Venetian Council offered him an annual pension of 200 ducats to remain. He also visited Bologna and Ferrara, and was on the way to Padua to see Mantegna, whom he much honored, but turned back on news of the death of that master, arriving at Nuremberg late in 1507.

Modern research has shown that the real cause of Dürer's visit to Venice was a commission from the German merchants of Venice to paint a large altarpiece for their chapel in San Bartolommeo. This picture, long in Strahow Abbey, Prague, is now in the Rudolphinum of that city. It has been much damaged by restoration, but even now we can see that it must have been wonderful in composition and color. Its subject is the "Feast of the Rose Garlands," and it represents the Virgin and the Christ Child giving wreaths of roses to the Emperor Maximilian and to Pope Julius II, while St. Dominic and St. Peter look on like the bystanders. His "Christ with the Doctors" (1506), now in the Barberini Palace, Rome, was executed, as the inscription records, in the space of five days and is an unsatisfactory collection of heads and hands, most of them caricatures. Among his other works are the "Martyrdom of St. George" (1508), a very overcrowded composition, now in the Vienna Museum, and the Heller altarpiece, of which the original was destroyed. The "Adoration of the Trinity" (1511), in the Museum of Vienna, is admirable in color and in sentiment and contains a good portrait of the painter.

Among his other works of the second period are a small "Christ on the Cross" (1506, Dresden), exquisite in execution and sentiment: the "Madonna with the Finch" (1506, Berlin); and a "Madonna with the Pear" (1512, Munich). His "Adam and Eve" (1507) in Madrid (the Florence examples being copied or replicas), shows what he learned in Italy as to treatment of the nude. It is somewhat idealized, not a copy of the model, as was customary in Germany. His heads of the apostles James and Philip (1516, Uffizi) are of great strength, and his "Lucretia" (1518, Munich), a nude, is one of his few mythological subjects. Among his portraits are those of unidentified young men (at Vienna and at Hampton Court), probably German merchants of Venice, and another of a young woman, erroneously called Dürer's wife, at Berlin, all dating from 1516. The well-known but poorly executed "Charles the Great," with crown and sceptre, and "Emperor Sigismund" (both in the Germanic Museum, Nuremberg), date from 1512. He continued his work in engraving—designing the "Little Passion" in wood and engraving the same subject on copper. This was also the period of his so-called "Master Print" in line engraving, his "Triumphal Arch," and the wonderful drawings of the "Emperor's Prayer Book."

In the summer of 1520 Dürer, accompanied by his wife and servant, made a journey to the Netherlands which lasted over a year. His object was to meet the new Emperor, Charles V, when he landed at Antwerp, in order to obtain a renewal of the pension which he had enjoyed under Maximilian. He has left us an interesting journal of his journey, and he also kept a sketchbook, many of the leaves of which sur-

vive. He was received everywhere with great honor, especially by the painters of Flanders, whose guilds vied with one another in homage to the illustrious stranger. Antwerp offered him a pension of 300 florins, a house, and freedom from taxation, to remain; but his patriotism forbade.

Margaret of Parma, Regent of the Netherlands, received him with honor, and he painted a portrait of the King of Denmark. He was present at the Emperor's coronation at Aix-la-Chapelle, where his pension was renewed. But the most important result of his memorable journey was the influence of the early Flemish painters, especially that of the brothers Van Eyck in the Ghent altarpiece, upon his own painting, which now attained that excellence of color it had hitherto lacked. The last period, that of his greatest paintings, begins at this point. From 1521 date the portraits of Barend van Orley (Dresden Gallery), "An Unknown Man" (Boston Museum), and the banker Hans Imhof (Madrid)—from a purely technical point of view the best of his portraits—as well as "St. Jerome" (Lisbon Museum). In 1526 he completed the portrait of the Nuremberg councilors Johar... (Augsburg), Jacob Muffel, and... both in Berlin. The last two—Dürer's intimate friends—represent types of the thoughtful and the sanguine temperament. The "Holzschuher" has well been called "the pearl of all Dürer's portraits." (See Plate.) The head is of wonderful strength and character, and the difficult color scheme is skillfully handled; the hair is perfectly white, while the eyes are blue, the face ruddy, and the background bluish gray. The year 1526 also saw the completion of his "Four Apostles" (sometimes called the "Four Temperaments"), composed of two panels of lifesize figures of the Apostles John and Peter, Mark and Paul—Dürer's legacy to his native town. For years they remained in the council chamber of Nuremberg, until acquired, practically by force, for the Munich Gallery. They are Dürer's greatest paintings, and never did a painter's art produce stronger and more individual representations. The heads of the Apostles are dignified and sublime, the drapery is simple and majestic, and although the details are executed with great care, they do not detract from the general effect. The coloring is faultless, especially in the white and red robes of John.

Few artists have received more universal recognition than Dürer. He attended the Reichstag of Augsburg in 1518 as one of the representatives of Nuremberg and on this occasion drew the portrait of the Emperor. He was highly regarded and treasured as a friend by members of the ruling aristocracy of Nuremberg; he was associated with the greatest princes of the Empire, such as Frederick the Wise, Elector of Saxony, his earliest patron and lifelong friend; the Cardinal Archbishop of Mayence, Chancellor of the Empire; and the Emperor himself. His friendship with the chief leaders of the Reformation, Luther, Melanchthon, etc., is well known. His fame extended even to Rome, where Raphael sent him... requesting specimens of his own... in return. He was esteemed no less for his singularly sweet and upright character than for his art. "His art, great as it was, was his least merit," said Melanchthon. His piety was deep and sincere, his religious convictions profound.

A large controversial literature has arisen on the subject whether he was Catholic or Protestant. The expressions of his journal of 1520–21 certainly show the greatest admiration for Luther and approval of his doctrine, and he was also on friendly terms with the principal leaders of the Reformation. On the other hand, his message to the city council of Nuremberg, written on the back of the "Apostles," condemns the excesses of the Reformation. He died at Nuremberg, on April 15, 1528, of consumption, contracted in the Netherlands, and was buried in the churchyard of St. John. A fine monument by Rauch was erected to him in the Fischmarkt, where his house, now used as a Dürer Museum, still stands.

Most of Dürer's works are signed with his qu... and are dated.

most important,  was not only the most representative, but he was the artist that Germany has ever produced. As Michelangelo in Italian art, so Dürer was the man of destiny in German art. Before him it was crude, and its technical qualities had not been perfected. He completely transformed, almost recreated it. Dürer was, above all else, a draftsman, who translated all appearances of nature into lines. He not only executed careful studies for all his pictures and for his copper engravings, but sketched and drew many subjects for their own sake. The finest collection of such drawings is in the Albertina, Vienna, which has above 100. Next to this is the British Museum, and after that Berlin. His drawings were all finished with care and exactness, and they were executed on various materials, with the pen, pencil, and brush. Sometimes they were outlined in water colors, sometimes studies on paper and parchment in body color. In the Augsburg Gallery there is a life-size Madonna in body colors; other famous examples are Dürer's "Mother" (1514, Berlin) and his wife, inscribed "Mein Agnes." He also painted a few water-color landscapes, which show fine observation and technical ability; a noted example is the "Mill" (Berlin). Among his tinted drawings are "Women Bathing" (Bremen) and "Venus with Cupid Stung by Bees" (British Museum). His famous "Green Passion" (Albertina), a series of pen and brush drawings on green paper, ranks with his best engravings. Among his best pen-and-ink drawings are the "Adoration of the Kings" (Albertina), and... the "Prayer Book of the Emperor..." (Munich Library), in which he decorated the borders of 45 pages with drawings in red, green, and violet ink.

Dürer was easily the most prominent engraver of his day and probably the very greatest of all times. In this art his imagination, his facility and invention had room for full play. Before his day woodcuts were mere outlines, and copperplates consisted of dark figures on light backgrounds. Dürer introduced light and shade into engraving, giving it tone and thus making it pictorial. He designed more than 100 woodcuts, four great series, besides many single plates. The "Apocalypse" series (16 blocks, published 1498) shows his mastery of the art, and an extraordinary fantasy in making tangible the mystic visions of St. John. The fourth block, representing the "Four Riders of the Apocalypse," is especially good. His "Great Passion," a series of 12 plates, was produced for the most part in

1500, though published in 1511. His "Life of the Virgin," a charming series of 16 blocks, was executed chiefly in 1504-05 and published in 1511. The "Small Passion" is a series of 37 blocks, executed in his best period (1509-10). We can but wonder at the invention displayed in the different versions of the same event, as compared with the "Great Passion." The "Triumphal Arch of Maximilian," executed after 1512, was a series of 90 plates so engraved as to form a triumphal arch 10 feet high. The subjects of the different plates were laudatory of the Emperor, and of these 24 were by Dürer, including the chief subject, the "Triumphal Car," containing the Emperor and his family.

In line engraving Dürer is equally renowned. His first works are executed in the manner of Schongauer and Mantegna—dark figures on a light background. Another interesting group of his copperplates is identical, except that the figures are reversed and better executed, with those of another engraver, whose signature was "W," probably Wohlgemuth. It is uncertain whether the original design was by Dürer. Among his best engravings of this group are the "Knight and Lady," the "Madonna with the Monkey," the "Dream," the "Four Witches." He soon progressed to a better manner, using a dark background. Among the prints of this description are the famous "Adam and Eve" (1504); "Christmas"; "Family of Satyrs" (1505); and the "Small Passion" (16 plates, 1512-13). Afterward he attempted etchings, but not with equal success. He presently combined both methods, first etching the plates and then going over them with the graver. These are the very best copper engravings he ever did, and in their beautiful silver tones they display the perfection of pictorial charm in an engraving. Among the best are the "Virgin Crowned by Angels," the "Virgin with the Child," and the weird "Death and the Devil" (1513), the well-known "St. Jerome in his Study" and the strange "Melancholia" (1514), the three last being known as his "Master Prints." He also engraved the portraits of celebrated contemporaries, such as the large and smaller portraits of Cardinal Albrecht of Brandenburg (1519, 1523), Frederick the Wise and Pirkheimer (1524—his two finest portraits on copper); Melanchthon and Erasmus (1526). Many of his engravings abound in a delightful humor, like the "Love Offers," "Love Offers," and others mentioned above, which are regarded by some as the foundation of genre in modern art. See Plate of ENGRAVING.

Dürer also occupied himself with sculpture and architecture, but none of the sculptures bearing his monogram are unquestionably genuine. The last years of his life were spent largely in literary activity, in pursuance of a patriotic design for a revival of German art, which he hoped to further by his writings.

Bibliography. DÜRER'S WRITINGS. The best edition of his letters, journals, and verses is by Lange and Fuhse, *Dürers schriftlicher Nachlass* (Halle, 1893); Eng. trans. of some of this material by Conway, *Literary Remains of Dürer* (Cambridge, 1889). His books on geometrical measurements and perspective, fortification, and art, were highly esteemed and translated into Latin, French, and Italian. The most important of them is *Vier Bücher von menschlicher Proportion* (Nuremberg, fol., 1528). On his art theories, see Müller, *Die Ästhetik Albrecht Dürers* (Strassburg, 1910).

LIFE AND WORKS. The copious literature on Dürer has been summed up by Singer, *Versuch einer Dürer-Bibliographie* (Strassburg, 1903). All the earlier lives of Dürer were superseded by Thausing, *Dürer, Geschichte seines Lebens und seiner Kunst* (2 vols., Leipzig, 1884)—the most complete work on the subject. Of great value also are: Springer, *Albrecht Dürer* (Berlin, 1892); and Wölfflin, *Die Kunst Albrecht Dürers* (ib., 1907), the ablest and most critical work on the subject, and Weisbach, *Der Junge Dürer* (Leipzig, 1906). The biographies by Kaufman (Freiburg, 1887) and Weber (Ratisbon, 1893) are controversial from the Catholic point of view; that of Zucker, in *Schriften des Vereins für Reformation Geschichte* (Halle, 1899-1900), is equally Protestant. English works are by Scott (London, 1869), Colvin (ib., 1877), Mrs. Charles Heaton (ib., 1881), Cust, in *Portfolio Series* (ib., 1897), and More (ib., 1905)—the last a very uncritical work. Consult also Nuchter, *Life and Selection from Works* (London, 1912), and Fry, *Journeys to Venice and to the Low Countries* (New York, 1912).

REPRODUCTIONS. Among the most important are the *Publications of the Dürer Society* (fol., London, 1898-1908), with introduction by Dodgson. Good reproductions with text are the works of Knackfuss, in *Kunst und Künstler* (Bielefeld, 1899); Scherz, in *Kunst und Künstler* (Stuttgart, 1904); *The Masters in Art Series* (1901; 1904). Most of his drawings have been published in facsimile by Lippmann (Berlin, 1883); those of the Albertina by Schönbrunner and Hader (Vienna, 1895 et seq.). See also Ephrussi, *Dürer et ses dessins* (Paris, 1882), and Colvin, *Ninety-Three Drawings of Albrecht Dürer* (London, 1898). His engravings have been published by Galichon (Paris, 1846-61) and Duplessis (ib., 1877); his copper engravings by Lübke (Nuremberg, 1876) and Leitschuh (ib., 1900).

DURESS (OF. *durece*, *duresce*, *duresse*, It. *durezza*, from Lat. *duritia*, severity, from *durus*, hard). That degree and kind of coercion, exercised over a person's will, which entitles him to avoid any contract, deed, or transfer of property made during its continuance, or which excuses his criminal acts.

As an excuse for crime, duress is narrowly limited by the common law. The victim of the coercion must show that he was driven to commit the act by threats of personal violence to him which induced a well-grounded apprehension of present death or grievous bodily harm. Even such threats would not excuse his killing an innocent person, for the view of the law was that he ought rather to die himself than escape by the murder of an innocent man. He would be justified, however, in killing his coercer. Modern statutes in some of the United States declare such extreme duress an excuse even for homicide (q.v.).

In civil matters, also, the common-law doctrine of duress is confined within rather narrow limits. Not every form of constraint, unfairly imposed by one party to a contract upon the other, will enable the victim to avoid the contract. Only actual or threatened violence or imprisonment amounts to common-law duress. Moreover, it must be exercised upon the person who makes the contract, or upon the husband, wife, parent, or child of such person; and it must be exercised or instigated or adopted by the one to be benefited by the contract. To amount to duress the

threats employed must be of grievous bodily harm and so made as to terrorize a man of ordinary nerve and courage, or they must be of unlawful imprisonment. The doctrine has been somewhat extended in the United States. According to the prevailing view, a person is under duress who is threatened with lawful imprisonment, provided the threat is made to overcome his will and does overcome it and is such as would naturally overcome the will of an ordinary man. A contract made by him in such circumstances does not have his free and true consent. It is imposed upon him by the threatener and is voidable.

A threat to detain or even to destroy property cannot operate as duress according to the narrow view of the ancient common law. In some of our States, however, duress of goods is recognized, and an owner who promises to pay illegal exactions in order to obtain possession of his property is allowed to avoid the promise. Even where the old common-law doctrine prevails, the owner who has paid such exactions may recover the money on the ground that the defendant had received money which belonged to the plaintiff. There must, however, be actual constraint to justify a recovery in such a case. Payment of an illegal claim "under protest" is a voluntary payment and will stand, unless it was enforced by actual detainer of property or person, or imminent danger thereof. See QUASI CONTRACT. See also INFLUENCE; CONSENT; and consult the authorities referred to under CONTRACT.

DURET, du'rá', FRANCISQUE JOSEPH (1804-65). A French sculptor, son and pupil of François Joseph Duret (1732-1816). He also studied under Bosio, and won the Prix de Rome in 1823. In 1833 he exhibited his "Neapolitan Fisher Dancing the Tarantella," now in the Louvre, a spirited statue in bronze, which established his reputation. In the same class is his "Neapolitan Improvisatore" (1839. Leipzig Museum). His works executed for public buildings include: "France Protecting her Children" (1855), a group in the grand style for the Louvre; two bronze caryatids for the tomb of Napoleon in the Invalides; a colossal Christ in the church of the Madeleine; the statues of "Comedy" and "Tragedy" for the Théâtre Français; marble statues of Dunois, Philippe of France, Chateaubriand, and Richelieu at Versailles; and the group for the fountain of St. Michel, representing that saint wrestling with Satan. He received the medal of honor in 1855 and was made a member of the Institute in 1845. As professor in the Ecole des Beaux-Arts, he was more influential through his teaching than through his works.

DURFÉ, dur'fá', HONORÉ. See URFÉ, HONORÉ D'.

DURFEE, dər'fē, JOB (1790-1847). An American jurist. He was born at Tiverton, R. I., graduated at Brown University in 1813, and was admitted to the bar. In 1814-19 and 1827-29 he was a member of the State Legislature, from 1821 to 1825 he was in the National House of Representatives as a Federalist, and in 1835 he became Chief Justice of the Supreme Court of Rhode Island. He was the author of *What Cheer?* (1832), a poem in nine cantos: of an oration, *The Influences of Scientific Discovery and Invention on Social and Political Progress*, or *Roger Williams in Exile* (1843), under the pseudonym "Theaptes"; and of a philosoph-

ical work in verse, entitled *The Panidea* (1846). Consult *Complete Works of Job Durfee, with a Memoir of his Life* (Providence, 1849), ed. by his son, and also Gibson, *Discourse on the Character and Writings of Chief Justice Durfee* (Providence, 1848).

D'URFEY, THOMAS (known as TOM DURFEY) (1653-1723). An English poet and dramatist, born at Exeter (Devon). He turned from the law to become a dramatist and made his first attempt as such in a comic-bombastic tragedy, *The Siege of Memphis* (1676). He was far more successful with his comedies, of which he wrote a considerable number. His popularity was greatly furthered by the songs written by him for his plays and set to music by Purcell and others. Soon he was called upon to compose occasional verse, much of it in glorification of the triumphs of English arms. By Charles II, James II, William and Mary, and Anne, he was shown marked tokens of favor. Latterly, it appears, he became reduced to poverty, and his friends, Addison and Steele, obtained for him a benefit performance of his *Plotting Sisters* at Drury Lane. He was a mirthful fellow, who, as Addison says, "made the world merry," turned out song after song with slight effort, and himself sang them with good spirit and applause. Several collections and recensions of his songs and poems, some with music, appeared between 1661 and 1720, the first entitled *An Antidote against Melancholy Made up in Pills*. He wrote further *Tales*, *Moral and Comical* (1706). His dramatic works were published contemporaneously, but have never been collected.

DURGĀ, dūr-gā' (Skt., impassable). In Hindu mythology, one of the names by which the consort of the god Siva is known. This is her title when she appears in her terrifying form. Similar is her awful name, Kālī, "Black," a dreadful goddess. Her image is often seen in Hindu temples. In her more pleasing aspect she is the same as Umā, Pārvatī (qq.v.). Her festival is the most popular of Bengal and is the occasion of universal rejoicing. Consult: Dowson, *Hindu Mythology* (London, 1879); Wilkins, *Hindu Mythology* (2d ed., ib., 1902); an article by B. Mazumdar in the *Journal of the Royal Asiatic Society* (1906).

DURHAM, dūr'am. A maritime county of the northeast of England, between the Tyne and Tees (Map: Durham, 12). It has 32 miles of coast, but with some cliffs, and an area of 1,187,474 acres, five-sevenths being arable. Durham is one of the chief counties in England for the production and export of coal and also for the mining of lead. Shipbuilding is an important industry, the establishments on the Tyne ranking next to those on the Clyde. Founding and metal working rank next, and there are also extensive manufactures of chemicals, paper, earthenware, glass, and bottles. More limestone is produced than by any other county in the United Kingdom. The agricultural products are oats, barley, wheat, turnips, beans, and peas. The Teeswater breed of short-horned cattle is well known, and excellent draft and saddle horses are raised. Pop., of the ancient or geographical county, 1901, 1,187,474; 1911, 1,369,860: of the administrative county, on which census returns are based, 1901, 768,624; 1911, 929,340. The capital is Durham (qq.v.).

Previous to the Roman invasion Durham was

DURHAM CATHEDRAL AND THE RIVER WEAR
FROM A PHOTOGRAPH

in the possession of the Brigantes and under Roman rule became part of the Province Maxima Cæsariensis. When the Anglo-Saxons gained control, it became part of Bernicia, and hence of the Kingdom of Northumbria, until the Norman Conquest. Under the Normans it obtained the privileges of a county palatine, and for many years its affairs were administered by the bishops, who enjoyed larger temporal prerogatives than in most of the other counties. In 1536 Henry VIII stripped them of many of their juridical powers, but it was not until 1836, after the death of Bishop van Mildert, that an Act of Parliament removed all temporal jurisdiction forever from the bishopric. *The Tyne and its Tributaries* (London, 1882); Lapsley, *The County Palatine of Durham* (New York, 1900); and the Surtees Society publications.

DURHAM (AS. *Dūnholm*, hill isle, from *dūn*, hill, down + *holm*, island). A parliamentary and municipal borough and ancient episcopal city of England, the capital of the County of Durham, 60 miles north-northwest of York. It is built around a steep rocky hill, 86 feet high, nearly encircled by the Wear, which is here crossed by three bridges (Map: England, E 2). On the top of the hill are the cathedral and castle. Ancient walls partly inclose the hill, from which fine views are obtained of the fertile wooded country and of the suburbs across the river. On the site of a church built by Bishop Ealdhune, in 995, Bishop William de Carlepho, about 1093, began the present magnificent cathedral, one of the finest Norman churches in England, to which additions continued to be made till about 1500. It thus exhibits the gradual changes of style between these periods. It is 510 feet long, 80 feet wide, 170 feet across the transepts, and 70 feet high. The central tower is 214 feet high, and the west towers each 138 feet. It contains the tombs of St. Cuthbert (q.v.) and the Venerable Bede. Among the chief buildings connected with the former monastery are the dormitory, now used as the new library, a magnificent hall in practically its original condition, and the refectory, now the old library. The castle—formerly the residence of the bishops of Durham, but now the seat of the University of Durham—was founded about 1072 by William the Conqueror. It was built in the Romanesque style, but it has since been much altered. The present University of Durham was opened for students in 1833. A royal charter in 1837 empowered the university to have two colleges. It has two colleges—Univ. of Durham and Bishop Hatfield's Hall. The city has many markets and public baths. Durham has long been famous for its mustard. The town sends one member to Parliament. Pop., 1901, 16,151; 1911, 17,550. Durham arose about the year 995, when Bishop Ealdhune brought here St. Cuthbert's bones from Ripon and built a church to enshrine them. It became the seat of the Bishop and Count Palatine of Durham County. Consult: *Bygone Durham*, ed. by Andrews (London, 1898); Low, *Durham* (ib., 1897); Bygate, *The Cathedral Church of Durham* (New York, 1899); Leighton, *Memorials of Old Durham* (London, 1910); Grierson, *Tales of English Minsters* (ib., 1910); Kitchin, *Story of the Deanery* (Durham, 1912).

DURHAM. A city and the county seat of Durham Co., N. C., 26 miles northwest of Raleigh, on the Southern, the Norfolk and West-

ern, the Seaboard Air Line, and the Durham and Southern, and the Durham and South Carolina railroads (Map: North Carolina, D 1). It is an important manufacturing centre for tobacco, cigars, and cigarettes, having one of the largest granulated smoking tobacco factories in the world. There are also cotton mills, sash and blind factories, foundries, a fertilizer factory, and other industries. Trinity College (Methodist Episcopal, South), opened in 1851, is located here. The city has also a school of fine art and a conservatory of music, a public library, and Watts Hospital. The government is administered under a charter of 1899 which provides for a mayor, chosen every two years, and a city council, elected on a general ticket. Settled about 1855, Durham was incorporated in 1869 with a population of 200. Near here General Johnston, with the Confederate army, surrendered to General Sherman on April 26, 1865. Pop., 1900, 6679; 1910, 18,241; 1914 (U. S. est.), 22,863.

DURHAM, JOHN GEORGE LAMBTON, first EARL OF (1792-1840). An English statesman, born in London. After an education at Eton he held a commission in the army for a short period. At 21 years of age he made a runaway marriage at Gretna Green with Harriet Cholmondeley, who died three years after. He married Lady Louisa Elizabeth Grey, daughter of Earl Grey, 18 months later, and by this union strengthened his political position. In 1813 he entered Parliament for Durham as an advanced Liberal. In 1828 he was created Baron Durham of the city of Durham. He was one of the four persons who prepared the Reform Bill and supported it in the House of Lords. In 1833 he was appointed Ambassador Extraordinary to Russia. After a second mission to Russia he was appointed in 1838 Governor-General of Canada, where a formidable rebellion had broken out. In his efforts to suppress the insurrection he exceeded the powers conferred upon him, and Lord Brougham, with whom he had differences, took advantage of the situation to interpellate him in the House of Lords. Incensed at a vote of disapproval, Durham returned to England without being recalled or obtaining the royal consent. The important report on Canadian affairs prepared under his direction by his secretary, Charles Buller, advocated liberal measures in colonial policy which were followed by his successors. He died at Cowes, Isle of Wight, in 1840.

DURHAM BOOK, THE. An edition of the Gospels, with Northumbrian-Saxon glosses, the work of St. Cuthbert, the sixth Bishop of Durham.

DURHAM CATTLE. See CATTLE.

DURHAM LETTER, THE. A letter of Lord John Russell to the Bishop of Durham in 1850, protesting against the invasion of Catholicism in the United Kingdom and especially in the Established church itself. It resulted in the passage of a bill, which, however, was not enforced, against the establishment of a Roman Catholic hierarchy in England.

DURIAN (Malay *duryon*), or **DURION** (*Durio zibethinus*). A fruit tree of the Malayan Archipelago, of the family Bombacaceæ. It is a lofty tree, with leaves resembling those of the cherry and with large bunches of pale-yellow flowers. The fruit is of the size of a large coconut: roundish oblong, with a hard thick rind, covered with soft spines, so that

it somewhat resembles a hedgehog rolled up. The pulp of the fruit is of creamy consistency and delicious taste, but has a smell which is very repulsive until a taste for the fruit is acquired. Persons accustomed to it, however, universally regard the durian as one of the very finest fruits of the East. In the Indian markets it commands a higher price than any other native fruit. It contains 10 or 12 seeds as large as pigeons' eggs, which, when roasted, are not inferior to chestnuts. One tree yields about 200 fruits in a year. For illustration, see Plate of DAHLIAS, ETC.

DURIE, or **DURY**, JOHN (1596-1680). A Scottish Protestant advocate of church unity. He was born in Edinburgh; his education was received at Sedan and Leyden, and most of his life was passed on the Continent. At home he held the position of chaplain to Charles I and Mary, Princess of Orange, and was a member of the Westminster Assembly. His reputation rests upon his though fruitless efforts to unite the Lutheran and Reformed, the Presbyterian and Congregational churches, an object for which he pleaded in every place to which his extensive travels brought him and with every prominent person he met. He died at Cassel, Germany, Sept. 26, 1680.

DÜRING, dū'ring, AUGUSTE. See CRELINGER, AUGUSTE DÜRING.

DÜRINGSFELD, dū'rings-fēlt, IDA VON (1815-76). A German author, born at Militsch, Lower Silesia, whose novels and books of travel were much read in her day. She was the daughter of an army officer and was a diligent student of languages, devoting herself to Italian and Bohemian folklore. She wrote a volume of poems entitled *Gedichte von Thekla* (1835; 2d vol., entitled *Für Dich*, 1850; 2d ed., 1865). Her other productions include: *Schloss Goczyn*, a novel (2d ed., 1845); *Magdalene*, a novel (1844); *Skizzen aus der vornehmen Welt* (1842-45); *Margareta von Valois*, a historical novel (1847); *Böhmische Rosen*, a collection of Bohemian folk songs (1851); *Lieder aus Toscana*, Tuscan folk songs (2d ed., 1859); *Das Buch denkwürdiger Frauen* (5th ed., 1896). Several works, including the celebrated collection of proverbs *Sprichwörter der germanischen und romanischen Sprachen* (2 vols., 1872-75), were also written by her in collaboration with her husband Otto von Reinsberg, who committed suicide on the day after her death.

DURIS (Lat., from Gk. Δούρις, *Douris*) OF **SAMOS** (c.350-c.280 B.C.). A Greek historian, a descendant of Alcibiades, and brother of Lynceus. At one time he was tyrant of Samos. He wrote a number of historical works, of which the most important was *Ἡ τῶν Ἑλληνικῶν Ἱστορία*, or *The History of Greece*, from the battle of Leuctra (371 B.C.) to the death of Lysimachus (281 B.C.). Both the judgments passed on him in antiquity and his remaining fragments support the belief that he was merely a careless and uncritical collector of historical materials. He wrote also on the theatre, on tragedy, and on the history of art. Consult: Müller, *Fragmenta Historicorum Graecorum* (Heidelberg, 1806); Hulleman, *Duridis Samii quæ Supersunt* (Utrecht, 1841); Bury, *The Ancient Greek Historians* (New York, 1909).

DÜRKHEIM, dūr'k'hīm. A town of the Bavarian Palatinate, Germany, on the Isenach, at the foot of the Hartz Mountains, about 13

miles west-southwest of Mannheim (Map: Germany, C 4). It is surrounded by vineyards and frequented as a health resort for the saline springs of Philippsballe, which belong to the town. Its chief industries are the manufacture of paper, oil, leather, and paints, and the preparation of salt, and a considerable trade in grain and sparkling wine is carried on. At the entrance to the Isenach valley are the picturesque ruins of the abbey of Limburg, founded in 1230 by Conrad II. It was destroyed by the French in 1689. Pop., 1900, 6207; 1910, 6523. Consult Schäfer, *Wegweiser für Dürkheim* (Dürkheim, 1896).

DURKHEIM, dūr'k'an', EMILE (1858-). A French philosopher, born at Les Vosges. He was educated at the Ecole Normale Supérieure, traveled in Germany, and made valuable studies of social conditions there. The first French chair in sociology at the University of Bordeaux was founded for him (1887), and he became a full professor six years later. His special aim was to separate sociology from mere psychology and to examine social conditions in relation to other observed social facts. In the field of psychology his writings treat of the distinctions between individual mental phenomena and "folk psychology." They include: "L'Individualisme et les intellectuels," in *Revue Bleue* (1898), and "Représentations individuelles et représentations collectives," in *Revue Métaphysique* (1898). Mention should also be made of his general study: "La science positive morale en Allemagne," in *Revue Philosophique* (1887); and of his books: *De la division du travail social* (1893); *Les règles de la méthode sociologique* (1894); *Le suicide* (1897); *Les formes élémentaires de la vie religieuse, le système totémique en Australie* (1912). He founded in 1898 and thereafter published annually *L'Année Sociologique*.

DURLACH, dūr'lāc. An old town in the Grand Duchy of Baden, Germany, on the Pfalz, 3 miles east of Karlsruhe (Map: Germany, C 4). Durlach manufactures tobacco, chicory, leather, gloves, brushes, chemicals, organs, sewer pipe, and machinery, and has extensive fruit and grain markets. The environs abound in orchards. On the summit of the Thurnberg overlooking the town is a lofty tower believed to be of Roman origin. Remains of ancient walls and fortifications are still to be seen. Pop., 1900, 11,400; 1905, 12,707; 1910, 13,896. Consult Fecht, *Geschichte der Stadt Durlach* (Heidelberg, 1869).

DÜRNSTEIN, dūr'n'stīn. A village of Lower Austria, situated in a highly fertile spot on the left bank of the Danube, about 10 miles west-northwest of Vienna (Map: Austria, D 2). It is noteworthy for the ruins of a castle where Richard Cœur de Lion is said to have been imprisoned three months in 1193. Near by, the French were defeated by the Austrians and Russians, Nov. 11, 1805. Pop., about 700.

DUROC, dūr'rōk', GÉRAUD CHRISTOPHE MICHEL, DUKE OF FRULI (1772-1813). A French soldier and diplomatist, born at Pont-à-Mousson. He was educated at the Military Academy of Chalons, joined Napoleon as sublieutenant of artillery at the siege of Toulon, and became one of his favorite officers. In the Italian and Egyptian campaigns he was Napoleon's aid-de-camp and at Marengo served as a brigadier general. During the Empire he was general of

division, grand officer of the Legion of Honor, and grand marshal of the palace. Because of his shrewdness and the confidence that Napoleon placed in him, he was sent on diplomatic missions to various European courts. He fought at Austerlitz, Aspern, and Wagram, and was killed in a skirmish near Markersdorf after the battle of Bautzen (1813). He was honored by burial in the Invalides at Paris.

DUROVERNUM. See CANTERBURY.

DURRA. See SORGHUM, *Nonsaccharine*; ANDROPOGON.

DURUM WHEAT. See WHEAT.

DURUY, dü'rwe', VICTOR (1811-94). A French historian and educator. He was born in Paris, Sept. 11, 1811, of obscure parents, his father being a workman in the lace works at Gobelins. Duruy did not begin his education until late in life, but was admitted in 1830 to the Ecole Normale Supérieure. He graduated in 1833 and became professor of history in the college at Rheims, but soon received a call to Paris, where for 25 years he held an honorable position in the Lycée Henri IV. An admirable teacher, he employed his spare time in the writing of textbooks on history and geography and soon became prominently known in the field of education. In 1853 he received the degree of Litt.D., but he did not leave the lycée until 1861, when he was made inspector of the Academy of Paris. He became successively *maître de conférences* at the Ecole Normale, Inspector General of Public Instruction, and, finally, professor of history in the Ecole Polytechnique. In 1863 Duruy was made Minister of Public Instruction by Napoleon III, whom he knew personally, having assisted that versatile ruler in collecting material for his *Vie de César*. For six years Duruy presided over the Department of Public Instruction, and to him is due in great part the modern system of education in France, especially the organization of secondary instruction. He was liberal in his views and devised many improvements in the educational system of France, which, however, his opponents, the Clericals and Conservatives, vehemently opposed. On the reorganization of the ministry in 1869 Duruy resigned his portfolio and was given a seat in the Senate. After the events of 1870 he retired into private life. The last years of Duruy's life were spent in historical research, the results of which were his great *Histoire des Romains* (7 vols., Paris, 1879-85), and his *Histoire des Grecs* (3 vols., ib., 1886-91). An English translation of the former of these appeared in London (1883-86). Most of his other works were school histories in Hachette's series *L'Histoire universelle*, the best-known volumes being the histories of Greece and Rome (Eng. trans., ed. by Mahaffy, London, 1888), and his *Student's History of France* (Eng. trans., New York, 1889). He died in Paris, Nov. 25, 1894. His son, Albert Duruy (1844-87), acquired some reputation as an historical writer on the period of the Revolution and as a Bonapartist partisan, while another son, Georges, born in 1853, has written a number of romances, historical and political. Consult Lavissee, *Un ministre, Victor Duruy* (Paris, 1895), and Bigelow, "Lavissee's Life of Duruy," in *American Historical Review*, vol. i (New York, 1896).

DURWARD, dēr'wērd. QUENTIN. The hero of Scott's novel of the same name.

DURYEA, dūr-yā' or dōr-yā'. A borough in

Luzerne Co., Pa., 9 miles south of Scranton, on the Lackawanna River, and on the Erie, the Lehigh Valley, and the Delaware, Lackawanna, and Western railroads. The chief industries are coal mining and the manufacture of silk. Duryea was incorporated as a borough in 1901. Pop., 1910, 7487.

DURYÉE, dur-yā', ABRAM (1815-90). An American soldier. He was born in New York City, was educated in the common schools, and afterward acquired considerable wealth as a dealer in mahogany furniture. He entered the State militia in 1833, became colonel of the Twenty-seventh Regiment (now the Seventh) in 1849, holding that office for 14 years. He took a conspicuous part in the numerous riots which marked that period. At the beginning of the Civil War he raised a regiment which became widely known as Duryée's Zouaves. He was promoted to be brigadier general of volunteers in August, 1861, but resigned from the service in January, 1863, owing to a disagreement over a question of rank. In 1865 he was brevetted major general for service at the battles of Cedar Mountain, Rappahannock Station, Thoroughfare Gap, Groveton, Chantilly, South Mountain, and Antietam. He was appointed police commissioner of New York City in 1873, and in the following year attacked and dispersed a company of communists assembled in Tompkins Square.

DUSART, dü-särt', CORNELIS (1660-1704). A Dutch genre painter and etcher, born at Haarlem. He was a pupil of Adriaen van Ostade (q.v.). His works are very uneven in quality, some of them equaling the work of his master, in whose style he paints; but most of them are inferior in color and draftsmanship. He usually represents kermesses, tavern scenes, and other popular amusements, and his peasant types frequently degenerate into satirical caricatures. The best of his works are in the galleries of Amsterdam, Dresden, Vienna, and Berlin. His etchings and engravings are very numerous, and his drawings much sought after. Dusart was also an art collector of some importance.

DUSE, dōō'zā, ELEONORA (1859-). An Italian actress, born at Vigonza, on the border of Piedmont and Lombardy. She was a family of actors, her grandfather having founded the Garibaldi Theatre in Padua, and she appeared on the stage when 13 years old. Her early stage life in itinerant companies was a succession of privations and hardships, which seriously impaired her health, but she was soon recognized at Naples, and a little later at Milan (1875), as the greatest actress of Italy and one of the greatest of her time. Her subsequent career was one of extraordinary success.

She won an international reputation at Vienna in 1892 and elicited successively enthusiastic responses in the principal cities of Europe. Her American début she made in January, 1893, as Camille, at the Fifth Avenue Theatre in New York City, and she appeared in London for the first time the same year. In 1897 she went to Paris, where she was regarded as the great rival of Sarah Bernhardt. Among her most noted presentations were those of Juliet, Francesca da Rimini, Marguerite, Camille, Fernande, Magda, and Paula in *The Second Mrs. Tanqueray*. To show her unusual versatility, she sometime plays on the same evening such contrasted rôles as Santuzza in *Cavalleria Rus-*

ticana and the rollicking heroine of *La Locandiera*. For several years she was closely associated with Gabriele D'Annunzio, and some of his best-known plays were written for her. Much of his success on the stage was undoubtedly due to her interpretation of his work. They quarreled in 1899, and while she continued to act in his plays, their former friendship never was renewed. Her art is distinguished for its simplicity, yet subtle intensity of expression. Discarding all make-up and many of the customary mannerisms of the stage, she gained her extraordinary dramatic power by the abandonment of much that is conventional but unreal in modern acting. In private life she is noted for her lack of personal publicity. Her marriage did not prove happy, and she separated from Signor Checchi. In 1902 she reappeared in America. After this she acted at intervals in Italy and made brief tours in Germany, but her health was such that she was compelled for the most part to live in retirement. Consult: Bracco, *Life of a Famous Actress*, with American press notices (New York, 1893); Mapes, *Duse and the French* (ib., 1898); Huneker, *Iconoclasts* (ib., 1905); Symonds, *Studies in Seven Arts* (London, 1906).

DUSHAN, STEPHEN. See STEPHEN DUSHAN.

DUSOMMERARD, dū'sôm'rär', ALEXANDRE (1779-1842). A French archæologist, born at Bar-sur-Aube. After serving in the army he was appointed a member of the Cour des Comptes in 1807, where he evinced decided Bourbon proclivities, and in 1831 he was made Master Councillor. He also devoted himself to archæological studies, traveled through France and Italy, and eventually became the founder of the famous Musée Cluny in Paris. This collection of mediæval implements and objects of art was begun by Dusommerard during the First Empire and was continued originally to decorate the dwelling of the Emperor, the so-called Hôtel Cluny. It finally became the greatest collection of its kind in France, and together with the mansion of Dusommerard was after his death bought by the government and converted into a museum, to which, with the adjacent Palais des Thermes was afterward added. Dusommerard began the work subsequently published under the title *Les arts au moyen âge* (1838-46) and containing more than 500 plates, and was the author of *Notices sur l'Hôtel de Cluny et le Palais des Thermes* (1834).

DUSSEK, dōs'shěk, JOHANN LADISLAUS (1761-1812). A Bohemian musician and composer. He was born at Czaslau, Bohemia, and received his earliest musical impulse as a boy singer at the Minorite Church, Iglau. His first teacher was Father Spenar, and his lessons were given during his attendance at the Jesuit College. After this he had a varied career, his reverses being chiefly due to love of luxury, lack of method, and ignorance of business. He has been rightly regarded as the pioneer of national music, and in his pianoforte playing he is credited with rivaling Clementi in the introduction and use of the "singing tone." His compositions, which include 12 concertos, 53 piano sonatas, 80 violin sonatas and much chamber music, were very popular in their day, but are forgotten to-day. A pianoforte method published in London had a very extended vogue. He died at Saint-Germain-en-Laye.

DÜSSELDORF, dū'sel-dōrf. The capital of

the government district of Düsseldorf, in the Prussian Rhine Province, situated in the centre of a fertile district, on the right bank of the Rhine, at the confluence of the Düssel with that river, 24 miles by rail north by west from Cologne, in lat. 51° 13' N., long. 6° 46' E. (Map: Prussia, B 3). Düsseldorf is divided into five main parts: the Altstadt, the original town, on the right bank of the Düssel; the Karlstadt, founded in 1786 by the Elector Karl Theodor, on the left bank; the Neustadt, on the Rhine, laid out between 1690 and 1716; the Friedrichstadt, to the south; and the suburb of It also takes in the suburbs of Bilk, Flingern, and Derendorf. The Altstadt has narrow, irregular streets, but for the most part Düsseldorf is well built and abounds in broad, well-shaded avenues and fine squares. A colossal bronze equestrian statue of the Elector Johann Wilhelm, who founded the famous picture gallery here in 1710—the greater part of which, however, was removed to Munich in 1805—stands in the Altmärkt.

Among the principal buildings of Düsseldorf are the town hall, dating from 1567, with a new wing added in 1885; the Academy of Art; the Kunsthalle with a municipal gallery of modern Düsseldorf artists; the handsome municipal theatre; the Provincial Ständehaus (House of the Rhenish Estates), in the Italian Renaissance style; the palace of justice; the Reichsbank; and the palatial new post office. Of the 37 churches (of which 26 are Roman Catholic), the most noteworthy are St. Lambert's (a Gothic edifice of the fourteenth century), St. Andrew's, Maximilian's, the new Gothic church of St. Mary, and St. Martin's. The latter is one of the finest public gardens in Düsseldorf, in it is situated the War Memorial, erected in 1892 to commemorate the campaigns of 1864, 1866, and 1870-71. Düsseldorf owns and operates a gas plant, its water works, street railways, and, since 1891, an electric plant. The educational institutions include a number of gymnasia and realschulen, a teachers' seminary, and an industrial art school. The town has been for two centuries an art centre and is the home of the famous Düsseldorf school of painters. The historic Academy of Art was founded in 1767. Among its pictures are an Assumption by Rubens, a Madonna by Bellini, and the remarkable fresco series by Janssen. The historical museum has a valuable collection of documents. There are also an industrial museum and a library with 50,000 volumes. Düsseldorf is one of the chief centres of the iron industry in Germany. It has, besides, a number of textile mills, breweries, distilleries, etc. The commerce is extensive. Düsseldorf is the seat of many consuls, including one from the United States. Like most German cities, it has increased in population remarkably during the last three decades, owing in part to the annexation of suburbs. In 1880 it had 95,190 inhabitants; in 1900, 213,711; in 1910, 358,728.

Düsseldorf was known as early as the twelfth century. It received municipal rights from Count Adolf of Berg in 1288 and in 1385 became the residence of the counts of Berg. In 1609 it came into the possession of the counts palatine of Neuburg, and subsequently became part of the Electoral Palatinate, which in 1779 was united with Bavaria. It prospered greatly under the counts and electors palatine, some of the chief buildings and institutions of the city dating

from that period. From 1795 to 1801 Düsseldorf was held by the French; in 1806 it became the capital of the Grand Duchy of Berg and was annexed together with the Grand Duchy to Prussia in 1815. Consult: Ferber, *Historische Wanderung durch die alte Stadt Düsseldorf* (Düsseldorf, 1890); Clemen, *Die Kunstmaler der Rheinprovinz*, vol. iii, part i, *Stadt und Kreis Düsseldorf* (ib., 1894); Brandt, *Studien zur Wirtschafts- und Verwaltungsgeschichte der Stadt Düsseldorf* (ib., 1902).

DÜSSELDORF SCHOOL OF PAINTING.

One of the most important, if not the most important, German schools of the nineteenth century. It was the outgrowth of the Academy of Art, founded at Düsseldorf by the Elector Palatine Karl Theodor in 1767, but did not attain importance until Düsseldorf became part of Prussia. The academy was reorganized by Frederick William III, who made Cornelius director. The latter did not hold his post long enough to impress his views upon the school, which represents rather the tendencies of Schadow, under whom it came into great prominence. While the school of Munich, under Cornelius, was a school of drawing, interested chiefly in frescoes, that of Düsseldorf was a real school of painting, which worked chiefly on panels and canvas, and paid some attention to color. It was technically superior to all the other German schools. More than any other school it represented the Romantic tendencies in Germany. In secluded Düsseldorf the artists lived apart from the world, entirely in the past, and transformed into painting the verses of Goethe, Shakespeare, and the rest. Their works, on the whole, bear unfavorable comparison with those of the French Romantic school, both from the standpoint of feeling and from that of technique. The school suffered much from dissensions between Catholics and Protestants, the former advocating strictly religious subjects, while the latter took a more liberal view. Among the most famous representatives of the school were Lessing, Hildebrandt, Sohn, Rethel, the Achenbachs, Knaus, and Deger (q.v.). It has had a great influence upon art in America, such men as Eastman Johnson, Leutze, and Bierstadt having done much to introduce its methods and style. The fine collection of old masters formerly possessed by the Düsseldorf Academy was transferred to Munich in 1805, but some 14,000 drawings and 24,000 engravings of the great masters still remain. Consult the works entitled *Die Düsseldorfer Malerschule*, by Fahne (Düsseldorf, 1837), Püttmann (Leipzig, 1839), and Rosenberg (ib., 1886); the monographs on *Die Düsseldorfer Kunstakademie*, by Wiegmann (Düsseldorf, 1854) and Woermann (ib., 1880); those entitled *Düsseldorfer Künstler* by Müller (Leipzig, 1854) and Blanckart (Stuttgart, 1877); Schaarschmidt, *Zur Geschichte der Düsseldorfer Kunst* (Düsseldorf, 1902).

DUSSIEUX, du'syè', LOUIS ETIENNE (1815-94). A French geographer and historian, born at Lyons. He became professor of history at Saint-Cyr in 1850. Besides his excellent contributions as a collaborator to the *Encyclopédie Nouvelle* and the *Annales Archéologiques*, he edited the *Mémoires* of the Marquis de Dangeau and of the Duc de Luynes, and the *Lettres intimes* of Henry IV, a work of considerable historical value. His original publications include: *L'Art considéré comme le symbole de l'état social*

(1838); *Essai historique sur l'invasion des Hongrois en Europe et spécialement en France* (1838); *Recherches sur l'histoire de la peinture sur émail* (1839-40); *Géographie historique de la France* (1844); *Le Canada sous la domination française* (1855); *Cours classique de Géographie* (1859-65); *Le Cardinal de Richelieu* (1885); *Etude biographique sur Colbert* (1886); etc.

DUST (AS. *dust*, Ger. *Dust*, connected with Ger. *Dunst*, vapor, OHG. *dunist*, *tunist*, breath, storm, Goth. *dauns*, odor, Skt. *dhvans*, *dhrvas*, to fall to dust, to perish), ATMOSPHERIC. It is a familiar fact that dust is always present in the atmosphere, not merely in houses and near the ground out of doors, but over the ocean and even on the tops of mountains. In order to obtain air absolutely free from dust, it may be filtered slowly through plugs of cotton wool, or it may be suddenly expanded so as to cool below the dew point, when a portion of its moisture will condense upon the particles of dust and cause them to settle quickly to the bottom of the vessel. When a beam of sunlight shines through dustless air, nothing is seen by an observer standing at one side, but if dust is present the sunlight is scattered in all directions and the beam of light is said to become visible. When atmospheric dust is collected and examined under a microscope, it is seen to consist largely of grains of pollen, bits of vegetable fibre, and hairs and all kinds of mineral fragments, including occasionally metallic iron. When, on the other hand, dust is allowed to settle upon properly prepared glass plates or the jellies and broths used for " " in bacteriology, and is kept in a warm room, there usually springs up in a few days a vigorous growth of fungi and bacteria, showing that living germs were present, although they may have been invisible in the ordinary microscope. Such dust gives rise in nature to growths that were formerly spoken of as spontaneous generation; but it is now abundantly demonstrated that they simply prove the previous existence of living germs. Some of these germs are highly injurious to men and animals and are the sources of epidemic diseases; others, when brought to the ground by means of rain, may germinate on the wet soil and produce characteristic fungi. These are sometimes black, giving rise to what is called black rain (q.v.); sometimes red, giving rise to red rain or blood rain and occasionally green snow or red snow. When yellow pollen is brought down and spread on the wet ground, it is often spoken of as a rain of sulphur. No fermentation, souring, festering, or other trouble caused by the development of bacteria and fungi can originate in absolutely pure air.

Showers of dust occur in connection with active volcanoes, prairie fires, forest fires, tornadoes, and strong winds, that elevate the dust in one region only to deposit it in another. Ordinary storm winds sweeping over a forest and robbing the trees of their pollen produce showers of sulphur or other forms of dust within a few hundred miles. Remarkable dust showers originate in the region of the Sahara in north Africa. This dust, which is exceedingly fine and usually red, has been transported 1200 miles to the north across the Mediterranean into Europe. (See the description of the dust storm of Feb. 25, 1879, on page 34 of *Bartholomew's*

Atlas of Meteorology, and that of the red dust of 1901 in *Nature*.) Almost as far to the west and southwest of the Sahara a fine white dust falls on vessels in the Atlantic Ocean during the so-called harmattan (q.v.), or very dry winds blowing out from the interior of the desert region. Examination of this dust shows it to be almost exclusively composed of the tests of diatoms—microscopic organisms, growing on the vegetation in the fresh water of the interior. The formation known in geology as loess (q.v.) is an exceedingly fine, friable soil, easily raised by the wind and carried to great distances. This formation exists in China in layers of several hundred feet in depth, and in the prairie region of North America to a depth of 100 feet or less, and is supposed by many to owe its origin entirely to the dust carried by the wind in certain seasons of the year. A shower of black snow due to this dust is described in the *United States Monthly Weather Review* for January, 1895, pp. 15-19. Among the most remarkable showers of dust and ashes are those that have attended volcanic eruptions, such as those of Vesuvius. The cloud of dust proceeding from Skaptar Jökull in Iceland during the . . . 20 to June 18, 1873, extend . . . 2000 miles, over all of Europe and still farther into Syria. The dust from an eruption of Cotopaxi was calculated by Mr. Whymper to represent 2,000,000 tons of material; that from the volcano Soufrière in the island of St. Vincent, West Indies, on April 30, 1812, fell on Barbados, 50 miles to the east, to the depth of 1 inch, and extended thence eastward beyond the horizon during May 1. The great eruption of ashes and vapor from Krakatoa in the Straits of Sunda, during Aug. 26 and 27, 1883, spread a cloud of dust and vapor over the whole globe between lat. 10° S. and 60° N., some of which, remaining at a great height, was observable three years later. The dust collected 900 miles west of the volcano was similar in composition to that collected only 100 miles distant. . . . of dust attended the eruptions . . . and St. Vincent in 1902 and produced striking sunset glows, similar to those that were developed by the ejected ashes from Krakatoa. Dust falls and atmospheric phenomena but slightly less marked than those of 1902 resulted from the great explosion of Katmai volcano, Alaska, June 6-10, 1912. (Consult H. H. Kimball in *Monthly Weather Review*, 1913, vol. xli, pp. 153-159.)

The great importance of dust in the formation of cloud and rain has been especially elucidated by the labors of Mr. John Aitken, of Falkirk, Scotland, who has shown that in the ordinary process of the formation of cloud or fog by cooling air the condensation of the moisture takes place first upon the particles of dust as nuclei; that, in fact, every particle of dust collects moisture, and that every particle of cloud or fog implies a nucleus of dust. On this fundamental principle Aitken has based the construction of his so-called dust counter, which he has made quite portable, and which enables one to determine with close proximity the relative and the absolute dustiness of any sample of air. He has made such determinations in many parts of Europe and in a great variety of places. The dustiest air is found in the cities; thus, in London, Edinburgh and Paris there are from 80,000 to 200,000 particles per cubic centimeter

(about the fifteenth part of a cubic inch). The air having least dust, so far as yet observed, is that of the western Highlands of Scotland—viz., from 7600 down to 10 particles per cubic centimeter; the air of the Swiss mountain tops has a similar small content of dust. Aitken's investigations have explained quantitatively that which was before known only qualitatively—viz., that the air most soothing to those who are troubled with delicate lungs is that which has the least dust. According to these results the presence of dust makes it easier for cooling air to form cloud or fog. Cloudy or foggy air must be considered as dustless air in which the dust previously existing is now replaced by minute floating globules of water. If, now, this dustless but foggy air is still further cooled, its surplus aqueous vapor, which does not easily condense upon the globules already present, supersaturates the dustless air, thus bringing about a condition of unstable equilibrium. This condition has been especially investigated by C. T. R. Wilson of the Cavendish Laboratory, Cambridge, England, who has shown that condensation eventually takes place, but only after a considerable additional cooling and with violence. In this process latent heat is set free and phenomena produced which imitate those observed in the interior of thunderclouds from which rain is falling. It would seem plausible to conclude, therefore, that, whereas dusty air is necessary for the formation of clouds, dustless air is necessary for the formation of rain.

When dust is very fine and uniform in size, it gives rise to beautiful optical phenomena due to the diffraction and interference of light, such as the wonderful red, green, and yellow sunsets and sunrises, and the blue suns visible during the daytime in the years 1883-85. These occurred in connection with the vapor dust from the Krakatoa eruption, but similar phenomena have been observed on numerous other occasions after volcanic eruptions.

Among the important works on this subject may be mentioned C. G. Ehrenberg, on *Infusoria* (Leipzig, 1838) and *Microgeology* (Berlin, 1856); J. W. Bailey, numerous papers in the *American Journal of Science*, from 1838 to 1856; John Aitken, numerous papers in the *Transactions of the Royal Society of Edinburgh*, and his paper, *Observations of Atmospheric Dust*, read before the Chicago Meteorological Congress of 1893 (see *United States Weather Bureau Bulletin No. 11*, pp. 734-754); Carl Barus, on *Cloudy Condensation* (see bulletins and reports of the United States Weather Bureau); G. J. Symons, *The Eruption of Krakatoa* (London, 1888); H. H. Kimball, "Meteorology of the Smoke Problem," in *Monthly Weather Review*, vol. xlii, pp. 29-35 (January, 1914).

Cosmic or Meteoric Dust. The fact that meteors entering the earth's atmosphere from interplanetary space are burned up and disappear leads to the rational conclusion that the resulting debris must remain in the atmosphere in the shape of very fine dust, or larger particles gradually descending to the earth's surface. In many cases the cloud left behind a meteor has remained visible for a relatively long period—in some cases three or four hours—during which it changes shape and diffuses, probably being illumined by the sunlight of a distant twilight like the so-called phosphorescent clouds. In a few cases the dust collected by Nordensk-

jöld from the surface of snow has been found to contain metallic iron and nickel. In still fewer cases hailstones have had a metallic nucleus. Arago first suggested that these metallic dusts are the remnants of the shooting stars or meteors; they have therefore been spoken of as cosmic or meteoric dust, but in all cases except those of metallic iron or nickel the ordinary mineral dusts undoubtedly come from the earth itself. Many volcanic eruptions send immense volumes of dust into the air; in 1883 Krakatoa sent up 4 cubic miles of solid rock ground into impalpable dust, the finest particles of which floated about for several years. Besides the larger shooting stars and aërolites, there may well exist even the dust in the interplanetary space, some of which must frequently enter the earth's atmosphere; but except in the case of the nickel-iron compounds it seems at present impossible to distinguish such cosmic dust from that which originates on the earth itself.

Dust Whirls and Dust Storms. The eddies of wind, especially those on a hot summer afternoon, that form small whirls of ascending hot air, carry up leaves and dust to a considerable height. Under most favorable circumstances these may be elevated to the level of the clouds, but under ordinary circumstances they are characteristic of the driest weather and scarcely rise 1000 feet before they subside. On the hot plains of India and the western arid regions of the United States, which are subject to very high temperatures in the sunshine, the dust column becomes a very tall column, with a rapid whirling motion, having a thin hazy axis, due to the condensation of aqueous vapor in the region of low pressure that must mark the central axis. The dust storms of India have been pictured and described best by Baddeley in his book under that name, published in London in 1880. He figures not merely isolated dust whirls, but groups of many such dancing around a central region, whence they are known as "dancing devils," or remarkable combinations of many whirls into figure " ", " ", " ", most complex forms of vortex " ", " ", of which are stable and some unstable. These are all caused by the rapid ascent and whirl of air that is heated intensely by contact with the hot soil and hot dust.

Dust Counter. An instrument invented by John Aitken for counting the total number of particles of dust in a small volume of air. In this instrument a definite quantity of air is suddenly and forcibly expanded, whereby it is cooled below the dew point, and immediately a fog or haze is formed within it whose density depends upon the quantity of moisture and the quantity of dust that is present. Within a short time these particles of fog descend to the bottom, falling upon a plate of black glass ruled off into small squares. With the help of a hand lens it is easy to count the number of particles per square, whence we calculate the number per cubic centimeter of air. Instead of this dust counter one may use Aitken's koniscope, in which we estimate the apparent cloudiness due to the dust. These instruments are described in his report in *Bulletin No. 11 of the United States Weather Bureau*.

The investigation of dust is an important branch of work in meteorology and in bacteriology, and the whole subject is known as kionology. Consult: P. Hubbard, *Dust Preventives*

and *Road Binders* (New York, 1910); T. M. Prudden, *Dust and its Dangers* (2d ed., ib., 1910); Robert Hessler, *Dusty Air and Ill Health* (Indianapolis, 1912).

DUST'AN, HANNAH (1657-?). A heroine of the early Indian wars in New England. At the time of the attack on Haverhill, Mass., March 15, 1697 (see HAVERHILL), the Indians captured Mrs. Dustan and her nurse, Mary Neff, and killed the youngest Dustan child, an infant only a week old. Mrs. Dustan's husband, Thomas Dustan, with their other seven children, however, managed to escape death. The captives were assigned to an Indian family consisting of two men, three women, and seven children, and were led off towards one of the larger Indian villages. On an island (now called Dustan's Island) 6 miles above the present Concord, N. H., Mrs. Dustan and her nurse, assisted by a captive English boy, Samuel Leonardson, killed and scalped all of their captors except one squaw and a small boy. After a toilsome journey they reached their homes in safety. The story of their exploit spread rapidly, was told and retold at New England firesides for several generations, and has furnished the theme for much romance and verse. The name is also spelled Dustin and Duston. Consult Mirick, *History of Haverhill* (Haverhill, 1832).

DUST BRAND. See SMUT.

DUSTYFOOT (OF. *piepoudreux*, ML. *pedepulverosus*, peddler). A court of summary jurisdiction established at fairs and markets in England for the speedy determination of commercial disputes arising between those who resorted to the same. Such courts, which were common in the Middle Ages on the Continent as well as in England, were also known as courts of piepowder. See COURT; LAW MERCHANT; PIEPOWDER; STAPLE.

DUSYANTA, dōō-shyān'tā. In Kalidasa's drama *Sakuntalā*, the husband of the heroine. He is of the lunar race, a descendant of Paru, and father of Bharata.

DUTCH EAST INDIA COMPANY. A trading company composed of smaller companies which were united in 1602. Its privileges included a monopoly of trade beyond the Cape of Good Hope and the Strait of Magellan and the power of making treaties, maintaining military forces, and founding forts. Batavia, in Java, became the capital of the Dutch East Indies in 1619. During the seventeenth century the company was very powerful in the Indian Archipelago and in South Africa. Its existence was terminated in 1798. See EAST INDIA COMPANY.

DUTCH EAST INDIES. The Dutch possessions in the Malay Archipelago constituting by far the greater part of that group and lying between lat. 6° N. and 11° S. and between long. 95° and 141° E. (Map: Australasia, D 3). They consist administratively of two main divisions: (1) Java (16 residencies) and Madura (Madoera) (one residency); (2) the "outposts," or "outpost provinces" (17 provinces). The division Java and Madura is a civilized region, densely populated and completely under Dutch control. In the outpost provinces some districts are under the direct supervision of Dutch officials, while others are administered through the medium of native chiefs; still other districts refuse to acknowledge Dutch sovereignty, as Achin (Atjeh) in northern Sumatra; and some in great part are virtually unknown, as

large areas of New Guinea and of the South and East districts of Borneo. The colony, as a whole, is administered by a governor-general appointed by the crown and assisted by a council, partly legislative and partly advisory in character. The capital is Batavia, a seaport city on the north coast of western Java. The area of the 16 residencies of Java, the one residency of Madura, and the 17 outpost provinces is shown in the table below. The population figures (the latest available in 1914) relate to the end of 1905 and are probably fairly accurate for Java and Madura; for the outpost provinces they are mostly approximations, in some cases merely official guesses.

DIVISIONS	Sq. miles	Pop., 1905
Java and Madura		
Java	48,686	28,604,719
Madura	2,090	1,493,289
Outpost Provinces		
Sumatra:		
Sumatra, West Coast ..	31,788	...
Padang Highlands		403,431
Padang Lowlands		905,040
Padang (Tj. Jelli) ..		413,301
Benkulen (Benkoelen) ..	9,437	204,269
Lampung Districts	11,338	156,518

Timor	17,782	308,600
Bali and Lombok	4,063	523,535
Total	739,559	37,979,377

* Consists of Indragiri in Sumatra and the Riouw and Billiton Islands, a part of eastern Celebes island, and a part of the Moluccas; the rest of the Moluccas are in the Dutch New Guinea extends to 141° E., with estimated area 152,428 square miles and estimated population 262,000.

The large towns are as follows, with population at the end of 1905: Batavia, 138,551; Surabaya (Soerabaja), 150,198; Surakarta (Soerakarta), 118,378; Samarang (Semarang), 96,600; Jokyakarta (Djokjakarta), 79,567; Pekalongan, 41,719 (the foregoing are in Java); Palembang, 91,440 and 60,985 (in Sumatra); Banjermasin (Bandjermasin), 16,708 (in Borneo); Macassar, 26,145 (in Celebes).

The total population exclusive of Dutch New Guinea was about 37,717,000. Of these the indigenes numbered 37,020,460 (Java and Madura, 29,715,903); Europeans, 80,910 (64,917); Chinese, 563,449 (295,193); "Arabs," 29,588 (19,148); other nonindigenous Orientals, 22,970 (2842). Exclusive of Dutch New Guinea, population by religion was returned as follows (Java and Madura in parenthesis): Mohammedan, 35,079,765 (29,627,557); Christian, 460,000 (26,000); Chinese and Japanese cults, 463,002 (293,844); Hindu, 170,444 (536); Animists, 789,187 (20,465); Jewish, 347 (236); other, 644,630 (67,880); total, 37,717,377 (including, in the outpost provinces, 34,139 indigenes unclassified).

In 1911 the imports of the Dutch East Indies were valued at 400,514,000 guilders and the ex-

ports at 521,600,000. Of these amounts, the private commerce, as distinguished from government, showed imports of 386,243,000 guilders and exports of 477,350,000. The share, in private commerce, of Java and Madura was 270,805,000 guilders imports and 299,863,000 exports. Value, in thousands of guilders, of the leading exports: sugar, 134,336; tobacco, 74,110; copra, 53,316; tin, 48,975; petroleum, 29,236; coffee, 25,025; tea, 13,610; pepper, 12,635; gums, 10,721; rice, 8300; hides and skins, 7445. The budget for 1913 showed estimated receipts of 273,608,208 guilders and estimated expenditure of 313,096,644 guilders. In 1913 the army consisted of 1178 officers and 31,762 men (9769 European and 21,993 native). The navy consisted of 24 vessels, aggregating 33,065 tons. See articles on separate islands and groups.

DUTCH GUIANA. See GUIANA.

DUTCH LANGUAGE. Dutch is the language of the inhabitants of the Netherlands and, in a strongly marked dialectic form, of the Boers in South Africa. It was also in general use in and about New York long after the cession of the province to the English, and is still current in two or three communities in New Jersey. The name Dutch is derived from *Dietsch*, meaning the vernacular, as distinguished from Latin. It is the same word as the German *Deutsch*, with which it is sometimes confounded, as in Pennsylvania Dutch and in the ordinary speech of uneducated persons. The Dutch themselves call their language *Nederlandsch*, while in German it is called *Holländisch*. Dutch belongs to the Low Frankish division of the Low German and is very closely related to the Flemish, with which it is now practically identical in its written form. Like the other Germanic languages it may be divided into three main periods: 1. Old Dutch, extending to about 1100. The only important monument of this period that has been preserved is a translation of the Psalter, with which it is now practically identical in its written form. Like the other Germanic languages it may be divided into three main periods: 1. Old Dutch, extending to about 1100. The only important monument of this period that has been preserved is a translation of the Psalter, with which it is now practically identical in its written form. 2. Middle Dutch, from 1100 to 1550. The language during this period suffered similar changes in sounds and inflections to those that can be observed in the contemporary English. As in English, no standard written form of the language was at first recognized, but each writer used his own dialect. In the thirteenth century a determined effort was made to assert the claims of a literary Dutch, the leader in the movement being Jacob van Maerlant (1235-1300). But in spite of all efforts the use of individual dialects continued. 3. Modern Dutch extends from 1550 to the present day. The most important single event in the history of the language during this period was the publication (1619-37) of the *Statenbijbel*, the authorized version of the Scriptures, which did much to spread the use of this form of Dutch in the Low Countries. The effect of this translation was similar to that of Luther's version upon High German, in establishing a standard of language and orthography that was

generally recognized as authoritative. During the eighteenth century the efforts to purify the language were carried to an absurd extent, and it therefore suffered greatly from the mistaken zeal of its users. During the nineteenth century a saner view of its spirit, based upon a more intelligent study of grammar and philology, has given greater freedom of expression. During the past 40 years efforts have been made to reform the language, and to effect uniformity of usage in Holland and Belgium, the present system having been adopted in Belgium in 1864 and in Holland in 1883.

The Dutch language is in its structure practically the same as the other members of the Germanic group of dialects. It belongs in its phonology to the Low German division, so that its consonants agree in general with the English (Dutch *te*, English *to*, German *zu*). Its orthography is somewhat awkward and does not represent the sounds of the language (e.g., *oe* = *ü*). In inflection and in syntax Dutch corresponds closely to German. It is written in the Roman alphabet and coincides in the use of capitals almost exactly with English.

The standard modern Dutch dictionary is *Woordenboek der Nederlandsche Taal*, ed. by M. de Vries, te Winkel, and others (The Hague, 1882 et seq.). For the older period of the language, Verwijs, *Middelnederlandsch Woordenboek* (The Hague, 1885-1912). The best etymological dictionary is Joh. Franck's (2d ed., 1912). Other dictionaries that deserve to be mentioned are: Verdam, *Middelnederlandsch Handwoordenboek* (ib., 1911); Dale, *Groot Woordenboek der Nederlandsche Taal*, ed. by Kuiper, Oppel, and Van Malssen (4th ed., ib., 1904); Nijhoff, *Woordenboek der Nederlandsche Taal* (ib., 1882-1913). For English students, there are Bomboff's (Arnheim, 1877), Calisch's (Leyden, 1890), and Bruggencate (The Hague, 1910). Of grammars in English may be mentioned Ahn's (London, 1891) and Hoogvliet's (7th ed., The Hague, 1908). The best account of the language outside of Holland is Jan te Winkel's in Paul, *Grundriss der germanischen Philologie*, vol. i, pp. 419-520 (2d ed., Strassburg, 1901-09). For the pronunciation of the Dutch language, see Ternerst, *Uitspraakleer der Nederlandsche Taal* (3d ed., Ghent, 1882).

DUTCH LIQUID (so called as being first prepared by an association of Dutch chemists), or ETHYLENE DICHLORIDE. An oily liquid obtained by passing ethylene gas into a warm mixture of 4 parts of water, 5 parts of sulphuric acid, 3 parts of common salt, and 2 parts of manganese dioxide, until the mixture assumes a yellow color, whereupon distillation yields the desired product. The mixture just specified produces chlorine, and the latter combines directly with ethylene to give ethylene chloride. Under normal atmospheric pressure ethylene chloride boils, according to Stadel, at 84.1° C. (183.4° F.). At the temperature of freezing water its specific gravity is about 1.28. It acts as an anæsthetic and has been shown to be safer than chloroform. Besides being very costly, however, it is liable to cause irritation of the throat and is therefore not used and little known. See CHLORIC ETHER.

DUTCH LITERATURE. The dawn of Dutch literature appears in the Middle Dutch sagas of Charlemagne and Arthur in the thirteenth century, adapted from the French epics and obviously intended for the nobility. Such

are Klaas van Haarlem's *William of Orange* (1911-1217), Dederic van Assenede's *Floris and Blanchefleur* (about 1250), an anonymous *Roland Song*, a *Gavein*, and a *Lancelot of the Lake*. *Reynard the Fox* was also done into Dutch about 1250. (See also MAERLANT.) The Dutch hymns of the thirteenth century are perfunctory, but there are folk songs and historical ballads of the fourteenth century of some merit. The general tendency in the first half of this century, here as in France, was towards commercial democracy. This appears in Maerlant (q.v.) and in his chief disciple, the moral chronicler Boendale (1280-1365), in Weert (died 1362), and Melis Stoke. With 1350 there is an aristocratic reaction, apparent before in the epics of Jan van Heelu and Hein van Aken (c. 1255-1330); but this movement expires in the early fifteenth century with Dirk Potter's *Course of Love*.

The *Levenswijze* was cultivated for the vulgar, and the *Levenswijze* was translated about 1300, a *Life of Jesus*, the gospel story popularly rendered; and the drama, sacred and semi-profane, shows characteristic traces of the Dutch genius for low comedy. During the fifteenth and sixteenth centuries literature in the Netherlands was dominated by the literary guilds, as burgher in tone as were the Meistersingers (q.v.). These, by public festivals, popular dramas, and social influence, made literature at once democratic and conservative. A new spirit came from the renaissance of classical learning in which Dirck Coornhert (1522-90) and Houwaert (1533-99) led, and Cornelis van Ghistele (fl. 1555-83) followed, but with less effect on letters than was exerted by the Reformation, through translations of the *Psalms* (1540, 1566, 1567) and hymns (1562 and 1569), and most of all by the battle songs of liberty and bitter political scorn of the *Geusen Liederen Boeckken* (1588). The stylistic reformers of this period were the Catholic Anna Bijns (1494-1567?) and the Protestant Van Marnix (1538-98).

From the close of the sixteenth century Amsterdam becomes the literary centre, for here only is thought free. Humanism is fostered by Hendrik Spiczer (1549-1612) and Roemer Vischer (1513-1620), and by the Latin scholars Grotius, Drusus, and Vossius. In the next generation the beautiful and accomplished daughters of Vischer, Anna (1584-1661) and Tesselschade (1594-1649), poets both, were the friends, admirers, and critics of the poets of the Dutch Augustan age, Vondel (q.v.), Hooft, Huygens (q.v.). In their salon the comedies of Bredero and his rival Coster, afterward a diligent cultivator of the dramatic shudder, were first discussed, and here Starter (born 1594), an emigrant from England, introduced to the Netherlands the Elizabethan lyric (1612-14). Cats (q.v., 1577-1660) escaped at Middelburg the Visschers's genial influence; nor is it recorded in the Amsterdam Bekker (1634-98), the most philosophical of writers in Dutch.

The immediate pupils of the classical generation were the dramatists Vos (died 1667), Brandt (1626-85), Van der Goes (1647-84), and Oudaen (1628-92), the epic poet Anso (1626-69), the didactic Dekker (1610-66), Vollenhove (1631-1708), the lyric Luiken (1649-1708), and Jonctijs (1600-52). Fiction was cultivated by Heemskerk, who emulated d'Urfé in his *Batavian Arcadia* (1637) and was himself imitated by Zoeteboom (*Zaanlandsche Arcadia*, 1658) and

Bos (*Dortsche Arcadia*, 1662), while Heinsius (q.v.) preferred to imitate Le Sage (*Mirador*, 1675).

Drama by 1700 was completely Gallicized and its influence and lyric poetry rapidly declined. Prose is the normal vehicle of the eighteenth-century thought. Here the first conspicuous figure is Van Effen, with his *Hollandsche Spectator* (1731-35), and the next ones the ladies Betjen Wolff (1738-1804) and Aagjen Deken (1741-1804), who in 1780 issued *Letters on Diverse Subjects* and followed this with three novels unrivaled in Dutch literature (*Sara Buigerhar*, 1782; *Willem Leevend*, 1785, *Cornelia Wildschut*, 1792).

The first signs of the contagion of German romanticism appear in Nieuwland (1764-94), but more obviously and effectively in Bilderdijk (q.v.), though he affected to scorn it as he did Shakespeare. Feith (q.v.) showed himself an avowed disciple of Goethe, and Simons (1755-1812) of Klopstock, though Dutch realism was not without its protesting witnesses in Perponcher (1741-1819) and Van Zon (Bruno Dallberg, 1758-1818). More national in his expression of romanticism is Loosjes (1761-1818), a novelist who continues the good tradition of Mesdames Wolff and Deken. Nationally romantic, too, are the poets Tollens (q.v., 1780-1856), Messchert (1790-1844), and Bogacrs (1795-1870), whose *Jochebed* (1835), *Voyage of Heemskerk to Gibraltar* (1836), and *Romances and Ballads* (1846) are probably the most significant Dutch poetry of his generation. Name-worthy, too, are the songs in lighter vein of Antoni Staring (1767-1840).

Since the middle of the century the achievements of Dutch scholars, especially in theology and history, deserve special recognition. The most striking novelists are Lennep (q.v.), E. D. Dekker (q.v.), and Maartens (q.v.); the best essayist, Hasebroek; noteworthy poets, Potgieter (1808-75), Nikolaas Beets (1814-1903), Pieter Genestet (1830-61), Da Costa (1798-1860), Albrecht Thijm (1820-89), Ten Kate (1819-89), and Emants (born 1848), and Louis Couperus (born 1863). Among critics are Reinier van den Brink (1810-65), Jan ten Brink, Jonckbloet, Huet, and Thijm.

About 1880 a new movement began as a part of the general European awakening. *De nieuwe Gids* was founded as the organ of the new school, which had no access to the old, conservative journal *De Gids*. The forerunners of this movement were the young lyricist J. Perk (1860-81), the celebrated M. Emants, and Helene Lapidother-Swarth. Willem Kloos, one of the foremost, issued his collected poems in 1894 and his critical essays in 1896. H. Gorter, A. Verwey, the more important F. Van Eeden, lyricist and dramatist as well as author of charming fairy tales, H. J. Boeken, the critic and novelist, K. J. L. A. Thijm (pseudonym, L. van Deyssel), E. J. de Meester, F. Netscher under French influence, A. Aletrino, Henriette R. Holst van der Schalk in socialistic novels, H. Heijermans in realistic dramas, and perhaps Steijn Streuvels in peasant stories, are among the most important. J. ten Brink has written a serviceable *Kleine Geschiedenis der Nederlandischen Letteren* (1877); Dr. Jonckbloet, a *Geschiedenis der Nederlandische Letterkunde* (2d ed., 1873); and Van Vloten, a *Schets van de Geschiedenis der Nederlandischen Letteren* (1879). Consult: Mone, *Uebersicht der niederländischen Volksliteratur älterer Zeit* (Tübingen, 1838); Hellwald, *Geschichte der niederländischen Literatur* (Leipzig, 1887); Kalf, *Geschiedenis der Nederlandische Letterkunde* (Groningen, 1906); L. Schneider, *Geschichte der niederländischen Literatur* (1887). For the new school, consult Willem Kloos, *Veertien Jaar Literatuur-Geschiedenis* (2 vols., 1880-96), and J. ten Brink, *Geschiedenis der Noord-Nederlandische Letteren in de XIXe Eeuw* (1904).

DUTCH WEST INDIA COMPANY. A trading company established in 1621, to which was granted monopoly of trade on portions of the American and African coasts, with the right of colonizing and maintaining military and naval forces, with which it plundered the Spanish and Portuguese settlements. It established the Dutch colonies of Brazil, New Netherlands, Guiana, the West Indies, and the Gold Coast. After its dissolution in 1674 a new company was formed which lasted until 1794.

DUTENS, du'tän', LOUIS (1730-1812). A French miscellaneous writer, born at Tours. After having spent his youthful years as tutor and later engaged in diplomacy, he finally settled in England, where he took Anglican orders and obtained a living of £800 and a pension. Mackenzie, the English Minister at Turin, left him £15,000. He devoted his affluent leisure to *Recherches sur l'origine des découvertes attribuées aux modernes* (1766), to an *Appel au bon sens* (1777), against the French "philosophic" vagaries of the time, and to *Considérations théologiques sur les moyens de réunir toutes les* . . . (1798), with many archaeological treatises, and three volumes of anecdotal *Mémoires d'un voyageur qui se repose* (1806). His most valuable service to letters was a collection and scholarly edition of the *Works of Leibnitz* (6 vols., Geneva, 1769).

DUTERTRE, du'tär'tr', JEAN BAPTISTE (1610-87). A French Dominican missionary, born at Calais. For 17 years he lived in the French West Indies, and he described them and their history in a *Histoire des Antilles habitées par les Français* (1667-71).

DUTIES. See CUSTOMS DUTIES.

DUTREUIL DE RHINS, J. L. See RHINS.

DUTROCHET, du'trô'shá', RENÉ JOACHIM HENRI (1776-1847). A French physiologist, born at Château de Néon (Indre). In 1808 he was appointed by Joseph Bonaparte head physician to the military hospital at Burgos, Spain, then devastated by typhus fever. He returned to France, however, in the following year and gave himself up exclusively to the study of physics and physiology. In 1831 he became a member of the Institute. The results of his researches are contained in his *Mémoires pour servir à l'histoire anatomique et physiologique des végétaux et des animaux* (1837).

DUTT, dü't, MICHAEL MADHU SUNDAR (1824-73). An Indian poet, born at Sagandari, in Bengal, India. He was educated at the Hindu College of Calcutta and, having become a Christian, at the Bishop's College. He began writing verses

in English while at Madras in 1848, but it was not until after his return to Calcutta in 1856 that he turned his attention to literary composition in his native Bengali. Between 1858 and 1861 he produced three classical dramas, *Sarmishtha*, *Padmavati*, and *Krishna Kumari*. The influence of the Greek and Latin epics, of Milton, and of Dante led Madhu Sudan to give up the traditional Bengali rhymes for blank verse, in which he produced *Tilottama*, and (1861) the epic which brought him recognition as the greatest Indian poet of his century, the *Meghanad-Badha*. Afterward he lived in England for a time, returning to Calcutta in 1867 to practice as a barrister.

DUTT, dūt, TORU (1856-77). A Hindu poet, born in Calcutta. From 1869 to 1873 she studied in Europe. She translated into English the *Vishnupurana* and wrote original verse in Hindustani, French, and English. Her first volume was *A Sheaf Gleaned in French Fields* (1876). It was followed by *Le Journal de Mlle. d'Arvers*, a romance published in Paris in 1879. Her *Ancient Ballads and Legends of Hindustan* (with *Memoir* by Edmund Gosse) appeared in 1882. Consult E. W. Gosse, *Critical Kitkats* (1896).

DUTTON, CLARENCE EDWARD (1841-1912). An American geologist, born at Wallingford, Conn., and educated at Yale, where he graduated in 1860. He was an officer in the volunteer forces during the Civil War, after which he began the study of geology, and in 1875 was detailed to assist in Major John W. Powell's survey of the Rocky Mountains. He was connected with the United States Geological Survey in 1880-91 and in 1887 was put in charge of the division of volcanic geology and seismology. His investigation of the Charleston earthquake of 1886, published in the reports of that survey, attracted wide attention and helped to develop scientific interest in the study of earthquake phenomena. Of particular value was the discovery of a method for determining the depth of the focus and also his observations on the nature and speed of surface wave motion. He was promoted to the rank of major in the army in 1890 and retired at his own request in 1891. In 1884 he was elected to the National Academy of Sciences. His publications include: *High Plateaus of Utah* (1880); *Tertiary History of the Grand Cañon District* (1882); *Hawaiian Volcanoes* (1884); *Mount Taylor and the Zuñi Plateau* (1886); *The Charleston Earthquake of 1886* (1889); *Earthquakes in the Light of the New Seismology* (1904).

DUTTON, EDWARD PAYSON (1831-). An American publisher, born at Keene, N. H. He was educated at the Boston Latin School. In 1852 he became a member of the Boston book-selling firm of Ide and Dutton, which in 1858 became E. P. Dutton & Co., with Dutton as president. In 1861 this company bought the retail business of Fisk and Fields and later also the business of the General Protestant Episcopal Sunday School Union and Church Book Society of New York. The main business, publishing and retail, was finally concentrated in New York. One of the firm's notable enterprises has been the *Everyman's Library* (J. M. Dent, English publishers), an important series of inexpensive reprinted classics in all departments of literature.

DUTTON, HENRY (1796-1869). An American

can jurist. He was born in Plymouth, Conn., and graduated in 1818 at Yale, where he became professor of law in 1847. He was Governor of Connecticut in 1854-55 and from 1861 to 1866 was judge of the Superior Court and of the Supreme Court of Errors. He published an analytical digest of the Connecticut Reports in 1833, was a member of the committees of 1849 and 1866 appointed by the Legislature to revise the statutes of the State, and in 1854 was chairman of a committee which compiled the State statutes.

DUTY OF WATER. The ratio between a given quantity of water used in irrigation and the area of crop to which it is applied. See IRRIGATION.

DUUMVIRS (Lat. *duumviri* or, more correctly, *duoviri*, from *duo*, two + *vir*, man). A committee of two; a general term in Roman administration, applicable to several officers. Most important was the function of *duoviri iure dicundo*, or 'duumvirs with judiciary powers,' the chief officers of many municipal towns. Every fifth year the duumviri exercised special censorial powers and were called *duoviri quinquennales*. In Rome there were *duoviri sacrorum* in charge of the Sibylline books, *duoviri navales* for the recruiting of the navy, etc.

DUVAL, dū'vāl', ALEXANDER VINCENT PINEUX (1767-1842). A French dramatist, born at Rennes. In his youth he was by turn sailor, engineer, actor, and finally director of the Odéon and member of the Academy (1812). As dramatist, he is considered a good painter of the life of his time. A collection of his plays is included in his *Oeuvres* (9 vols., 1822-23). Besides his plays, he wrote a romance, *Le misanthrope du Marais* (1832); *De la littérature dramatique* (1833), a critical study; *Le théâtre français depuis cinquante ans* (1838).

DUVAL, CHARLES ALEXANDRE AMAURY PINEUX (1760-1838). A French writer, brother of the preceding, born at Paris. He was Secretary of the French Legation at Rome, and upon his return to Paris was made a member of the Institute (1811) and of the Academy of Inscriptions (1816). His principal works are: *Des sépultures chez les anciens et les modernes* (1801); *Précis de la méthode d'éducation de Pestalozzi* (1804); *Monuments des arts du dessin chez les peuples tant anciens que modernes* (1829).

DUVAL, CLAUDE (1643-70). A notorious highwayman. He was born in Domfront, Normandy, but went to England as a follower of the Duke of Richmond at the time of the Restoration. Here he soon took to the life of a highwayman and became famous no less for his gallantry to women than for the extent and audacity of his robberies. He was finally captured, while intoxicated, and on Jan. 21, 1670, was executed at Tyburn. His body was buried in Covent Garden Church, where a memorial was erected bearing an inscription beginning with the lines:

"Here lies Du Vall: Reader, if male thou art,
Look to thy purse; if female, to thy heart."

Consult Smith, *Lives of the Highwaymen* (London, 1720), and Harper, *Half Hours with the Highwaymen* (2 vols., New York, 1908).

DU VAL, FRANÇOIS. See FONTENAY-MAREUIL.

DUVAL, MATTHIAS (1844-1907). A French physician and physiologist. He was born at Grasse (Alpes Maritimes) and was educated at

Strassburg, where he directed the ambulance service during the siege of 1870. Subsequently he joined the army of Bourbaki as chief of the medical staff. He was made professor of anatomy at the Ecole des Beaux-Arts, director of the anatomical laboratory of the Ecole des Hautes Etudes in 1880, and professor of histology and director of the Anthropological Institute in 1887. His more important publications (chiefly researches in anatomy and embryology) include: *Cours de physiologie* (trans. by E. Kuess, as *A Course of Lectures in Physiology*, 1876); *Précis de technique microscopique et histologique* (1878); *Manuel du microscope* (with Lereboullet, 1873); *Manuel de l'anatomie* (with Morel); *Atlas d'embryologie* (1889); *Eléments d'histologie* (1896).

DUVENECK, dū've-nĕk. FRANK (1848-). An American painter, sculptor, and etcher. He was born at Covington, Ky., and studied under Diez at Munich, where he lived for more than 10 years and formed a school of wide influence, composed chiefly of Americans, who accompanied him to Venice, Florence, and elsewhere on painting trips. After 1881 he spent much of his time in Florence; but he undertook the directorship of the McMicken Art School in Cincinnati. One of the first to introduce the style of the Munich school into America, he created a sensation in Boston in 1875 with five pictures, painted with unctuous brushwork and rich bituminous colors and with much brilliancy and dash. In later years his art changed in character and became lighter and cooler in color. Among his paintings are "A Circassian" (1875), a portrait of Dudley Warner (1877), "The Professor" (1878), "Turkish Page and Recumbent Figure" (Pennsylvania Academy), and nine paintings in the Cincinnati Museum. At the St. Louis Exposition in 1904 he exhibited a portrait of his mother and "The Yacht Harbor." The fine monument to his wife in the English Cemetery at Florence, Italy, contains deep emotional qualities and reveals a sculptor of great ability. He was elected to the National Academy of Design in 1906.

DUVERGIER DE HAURANNE, du'vâr-zhyá'de ô'rân', JEAN (1581-1643). A French theologian. He was born in Bayonne, studied at Louvain, where Jansen was his fellow student, and in 1620 was made Abbot of Saint-Cyran. He is often called "de Saint-Cyran." In Paris he formed a connection with the influential Arnauld family, and together with Angélique Arnauld, directress of the Convent of Port Royal, he completely reformed that institution. He made influential enemies and was imprisoned by Richelieu at Vincennes in 1638. After Richelieu's death he was released. See Jansenism; and consult the biography (Cologne, 1738) by Lancelot, his secretary.

DUVERGIER DE HAURANNE, PROSPER (1798-1881). A French publicist, born at Rouen. He was the son of Jean Marie Duvergier de Hauranne, a publicist and man of politics, and while still young collaborated with Rossi and Guizot on the *Globe* and later on the *Revue Française*. As deputy from Sancerre, he supported the views of Casimir-Périer and Thiers and became greatly opposed to the policy of his old friend Guizot. In 1848 he was elected a member of the Constitutional Assembly, and his Royalist opinions caused him to be arrested and exiled in the coup d'état that

followed. In 1852 he returned to France and wrote his *Histoire du gouvernement parlementaire en France de 1814 à 1848* (10 vols., 1857-70). For this and other writings he was elected a member of the Academy (1870). His articles contributed from time to time to the *Revue des Deux Mondes* are among the most important of his publications.

DUVERNEY, du'vâr'nâ', GUICHARD JOSEPH (1648-1730). A French anatomist, born at Feurs (Loire). His notably successful lectures on anatomy in the hall of Saint-Côme in Paris secured for him an appointment in 1679 to the professorship of anatomy at the Jardin du Roi. Perhaps no other Frenchman since Riofan did so much to advance the interests of the science, especially as regards the physiology of sight and the relation between the external and the internal ear. His researches are mainly embodied in his work entitled *Traité de l'organe de l'ouïe* (1683; frequently reprinted). His works also include *Traité des maladies des os* (1751), and *Œuvres anatomiques* (1761).

DUVERNOIS, du'vâr'nwâ', CLÉMENT AIMÉ JEAN BAPTISTE (1836-79). A French journalist and editor, born in Paris. He wrote considerably for various newspapers—*La Liberté*, *Le Courrier de Paris*, *L'Epoque*, and others. In 1868 he founded and became editor of *Le Peuple* (from 1869 *Le Peuple Français*), a journal inspired by Napoleon III, subsidized by government funds, sold cheaply, and made an important agency in strengthening the cause of the Empire among the masses. He was in 1869 elected a deputy from Hautes-Alpes in the Corps Législatif. In 1870 he moved a vote of lack of confidence in the Ollivier cabinet, thereupon succeeded by the Palikao ministry, in which he assumed the portfolio of Commerce and Agriculture. After the revolution of the Fourth of September, he withdrew to England, but returned in 1871 and founded *L'Ordre*, an Imperialistic sheet, conducted after the fashion of *Le Peuple*. The failure for large amounts of the Territorial Bank of Spain, of which he was a director, brought upon him two years' imprisonment for fraud. He published several works on contemporary politics.

DUVERNOY, du'vâr'nwâ', GILLES LOUIS (1777-1855). A French naturalist born at Montbéliard. He was invited to assist him in his work on comparative anatomy, and edited the last three volumes of Cuvier's *Leçons d'anatomie comparée*. After practicing medicine for 20 years, he was chosen professor of natural history at Strassburg in 1827, and from 1837 until his death was a professor in the Collège de France, first of natural history and afterward of comparative anatomy. His publications include *Leçons sur l'histoire naturelle des corps organisés* (1839), and *Mémoires sur le système nerveux des mollusques acéphales lamelli-branches ou bivalves* (1853).

DUVEYRIER, du'vâ'ryâ', HENRI (1840-92). A French explorer. He was born in Paris, studied geography and Arabic in Germany, and for a time was associated with the African traveler Heinrich Barth, in London. He subsequently returned to Paris, and devoted himself to the study of the natural sciences. He explored the northern Sahara, and finally penetrated to the centre of the Sudan. On his return he published *Exploration du Sahara: Les Tûdreg du Nord* (1864); and received from the Société de Géographie in Paris its gold medal. His

works also include *La Tunisie* (1881), and *La confrère musselmanne de Sidé Mohammed Ben Ali-Es-Senóusi* (1884).

DUX, dŭks (Bohemian *Duchcov*). A town of Bohemia, situated about 18 miles west-southwest of Aussig. The castle of Count Waldstein, kinsman of Wallenstein, contains a picture gallery, a library, and many relics of Wallenstein. It has a school of mines. The town has manufactures of glass, pottery, porcelain, sugar, flour, and beer. Near by are lignite mines. Pop., 1900, 11,921; 1910, 12,399.

DUYCKINCK, dŭ'kĭnk, EVERT AUGUSTUS (1816-78). An American editor, born in New York City. He was educated at Columbia College; traveled in Europe, and made early contributions to periodicals. From 1840 to 1842 he edited, with Cornelius Mathews, the monthly *Arcturus*. From 1847 to 1853, with a year's break, he edited, with his brother George Long (1823-43), the *Literary World*, an important weekly review. In 1854-55, again with his brother, he prepared the two volumes of the well-known *Cyclopædia of American Literature*, a most useful publication. A full list of his voluminous biographical works and of his literary compilations is unnecessary, but a few titles may be given: *Wit and Wisdom of Sydney Smith* (1856); *History of the War for the Union* (1861-65); *Poems Relating to the American Revolution* (1865); *Poems of Philip Freneau* (1865); *National Portrait Gallery of Eminent Americans* (1866). Consult W. C. Duyckinck, *Duyckinck and Allied Families* (1908).

DUYCKINCK, GEORGE LONG (1823-63). An American editor and author, born in New York City. He graduated at the University of New York in 1843; was admitted to the bar, but never practiced law; and was associated with his brother (E. A. Duyckinck) in the preparation of *The Cyclopædia of American Literature* (2 vols., 1855; 3d ed., 1875). His strong interest in all that pertained to the Protestant Episcopal church induced him to undertake a series of biographies of English clergymen of that church. The volumes are *George Herbert* (1858), *Thomas Ken* (1859), *Jeremy Taylor* (1860), *Hugh Latimer* (1861). Consult W. C. Duyckinck, *Duyckinck and Allied Families* (New York, 1908).

DUYKER. See **DUKER**.

DUYSE, doi'ze, PRUDENS VAN (1804-59). A Flemish poet, born at Dendermonde. He served as archivist in his native town, and afterward at Ghent; was a member of many learned societies in Belgium and France, and contributed greatly to the revival of Flemish literature, both by his poems and dramas and by studies in the history and literature of Flanders. He was less remarkable for genius than for fertility, though several of his productions in both prose and poetry obtained prizes from literary societies. His more important poetical publications, issued at various dates from 1836 to 1859, are: *Vaderlandsche Poëzy* (Patriotic Poetry); *Natalia* (Birthday Poetry); *Elgiën*; *Gedichtjes voor Kinderen* (Poetry for Children); *Het Klaverblad* (The Cloverleaf), and *Nieuwe Kindergedichtjes* (New Poems for Children). His comic works were edited by F. de Potter (Brussels, 1861).

DVINA, dvé-ná'. An important river of north Russia, formed by the union of the Sukhona and the Jug, at the town of Veliki Ustug, Government of Vologda (Map: Russia, F 2). It flows northeasterly to its junction with the

Vitcheгда, and then, turning to the northwest, enters the White Sea by a wide estuary, about 26 miles below Archangel. Its length is over 760 miles from the source of the Sukhona and over 1100 miles from the source of the Vitcheгда. It is navigable from its junction with the Vitcheгда, a distance of over 400 miles. The basin has an area of over 140,000 square miles. The chief tributaries are the Vitcheгда, which exceeds in the volume of its waters the upper course of the Dvina, the Pinega, and the Vaga. The Vitcheгда, Jug, and Sukhona are navigated by steamers. The Dvina is connected by canals with the Volga and the Neva. The river freezes in winter, and is closed to navigation from the last week in October to the first days of May. Fish abound; the lower course of the river is the home of the navaga, a variety of cod unknown elsewhere.

DVINA, SOUTHERN. See **DŮNA**.

DVOŘÁK, dvor'zhák, ANTONÍN (1841-1904). A famous Bohemian composer, born at Mühldhausen, Sept. 8, 1841. He was to follow the occupation of his father, the butcher and innkeeper of the village, but, upon the advice of Dvořák's schoolmaster, his first teacher in singing and violin, he was sent, at the age of 12, to Zlonitz to study the piano, organ, and theory of music, and, two years later, to Kamenitz, where he remained for a year with the organist Hancke. In 1857, on his father's promise of a small allowance, he entered the organ school of the Society for Church Music at Prague. Shortly afterward the meagre pittance was cut off, and the composer had to make a living by playing the viola in small bands and cafés, until, in 1862, the orchestra of which he was a member was engaged at the newly opened Bohemian Theatre in Prague, which in 1871 became the National Theatre. Here he became acquainted with Karl Bendl, and through him first obtained access to orchestral scores of Beethoven's compositions. The study of original scores induced him to try his hand in the larger forms, and he wrote symphonies, an opera, and chamber music, though his first important work to be heard, the cantata *Die Erben des weissen Berges*, was not given until 1873. Its success was quite out of the ordinary, and the Austrian Government, after a time, granted him, for his *Sounds from Moravia*, an annual stipend of \$160, later increased to \$240. The composer now heard *Die Meistersinger*, and set out to write a comic opera, *The King and the Collier* (1874). The score proved such an unproducible monstrosity that it had to be rewritten from the first bar to the last, and then it won quite a success (1875). About this time, through the offices of Hanslick and Brahms, the judge who had awarded him the stipend, Dvořák received an order from Simrock, of Berlin, and the resulting set of *Slavonic Dances* for pianoforte duets rivaled Brahms's *Capriccio*. In their sudden and continued popularity. But his greatest success awaited him in England. In 1883 his *Stabat Mater*, once rejected by the Austrian Government jury, stirred up a genuine furor, and thereafter England became the home of his musical activity. *The Spectre's Bride* (cantata, Birmingham, 1885) repeated the success of *Stabat Mater*. *St. Ludmilla* (oratorio, Leeds, 1886) and the *Requiem Mass* (1891) were other works written for English festivals. In 1892 he was engaged as director of the New York National Conservatory at a salary of \$15,000 a year, a

post which he held for three years. While in the United States he grew interested in the music of negroes and Indians to the point of introducing their melodies into his symphony *From the New World*, and the overture *In Nature*. After 1895 he lived in Prague, writing in 1899 the opera *Der Teufel und die wilde Kathe*. He was made an honorary member of many musical organizations, and the degree of Doctor of Music was conferred upon him by the universities of Prague and Cambridge. Later he was called to the Austrian House of Peers. Besides much chamber music, he wrote five symphonies, many sacred compositions, and a number of operas which enjoy great popularity in his native land. His pianoforte compositions are the least significant portions of his contributions to contemporary music. After his death (May 1, 1904) there were found among his papers three more completed symphonies, which were edited by his son-in-law Josef Suk (q.v.). With Smetana (q.v.) and the Young Russian School, Dvořák has called the world's attention to the inexhaustible wealth of folksongs possessed by the Slavs. While strongly national in the character of their music, the Slavic composers, and Dvořák among them, as a rule do not transplant the folk themes bodily, as did Liszt with the Magyar melodies. They imbue their music with the national spirit, which is most striking in rhythms and harmony; and in this line Dvořák's themes, though at times cheap in texture, carry the musician away by the sheer force of their originality and freshness. A master of orchestral color after long years of practical apprenticeship in the orchestra, Dvořák reveals his weakness when he writes within the boundaries of the new forms, in which he had little training beyond his own studies of scores. Yet to this very independence the world is indebted for the introduction of new forms—the Dumka (literally a little musing, a sort of intermediary between elegy and ballad) for the slow movement, and the Furiant (a sharply accented Bohemian dance of vertiginous rapidity and everchanging rhythm) for the scherzo. Consult: Zubatky, *Dvořák* (Prague, 1886); D. G. Mason, *From Grieg to Brahms* (New York, 1902); W. H. Hadow, *Studies in Modern Music*, vol. ii (New York, 1904).

DWALE. See BELLADONNA.

DWAMISH. See SALISHAN STOCK.

DWARF (AS. *dweorg*; *dweorh*, Icel. *dvergr*, OHG. *tuwerg*, Ger. *Zwerg*). In general, an undersized (and usually stupid) human being. The term is sometimes applied to the Akka (q.v.) tribe, and some other peoples in Central and Southern Africa, the Andaman Islands (see MINCOPIES), the peninsula of Malacca (see SEMANGS), and the Philippines (see AETA). The dwarf tribes that are grouped around the lowest limits of human stature have always been a subject of great interest, both to laymen and to scientific men. However, the term Pygmy is now generally applied to people whose shortness of stature is a racial trait and not the result of pathological conditions. A large part of this interest is probably due to the widespread curiosity with regard to the abnormal, such as has from time immemorial centred in those rare departures from average height occurring among civilized races. Dwarfs, according to current terminology, are really the result of an anomaly of development, and usually manifest what are known as pathological characters.

Thus, most cases of dwarfism show traces of rickets (q.v.), which is a disorder of nutrition, where the process of ossification is arrested at a period when the bony tissue is about to become thoroughly ossified. In many instances dwarfs are well formed, and, to all appearances, perfectly normal in physical and mental characteristics. It has been observed that, in contrast with the giants, the mind of dwarfs is acute and active; in character they are often sensitive and revengeful.

Pathologically dwarfism or microsomia includes two classes, the pure dwarfs, miniature but well-formed people, and the common infantile dwarfs, sometimes called "type Lorain," following congenital or acquired diseases.

Dwarfism, as seen in Europe and the United States is due in a large majority of cases to cretinism (q.v.) or infantile myxedema. This is a disease of the thyroid gland. The cretin dwarf is abnormal mentally as well as in physical proportions. The head is relatively large, the lips thick, the skin and hair coarse, the spine bent, and pelvis deformed. Mentally he is inferior and may be idiotic. Other diseases resulting in dwarfism are Mongolian idiocy, achondroplasia (characterized by great shortening of the extremities), severe types of rickets, and spinal tuberculosis.

Formerly dwarfs were attractions in the entourage of kings; since then they have generally been exhibited for gain. Perhaps the most remarkable of these little folk is the feminine dwarf Hilany Agyba, of Sinai, 15 inches in height. The height of the celebrated Bébé of King Stanislas, of Poland, was 89 centimeters; another, 25 years of age, and 56 centimeters in height, was presented to Henrietta of France in a pie. The hunchback dwarfs of Philip IV were immortalized by the great Spanish painter Velazquez. Topinard has observed dwarfs that weighed as low as from 4 to 8 kilograms. The infrequency of dwarfs among the lower races of mankind is probably due to natural selection, as well as to the custom of destroying abnormalities.

Stories of dwarfs, brownies, elves, etc., are familiar in the folklore of nearly every tribe on earth, though the greatest development of these myths seems to be among the peoples of Aryan descent. Lately a theory has been advanced that the belief in brownies in England is a survival from ancient times, when a small, dark race of aborigines inhabited the country, and that the folk tales have an actual basis of fact. See PYGMIES.

Bibliography. Man, *Aborigines of the Andaman Islands* (London, 1873); Schweinfurth, *Heart of Africa* (ib., 1885); Junker, *Travels in Africa*, trans. by Keane (3 vols., ib., 1890-92); Tyson, *Philosophical Essay Concerning Pygmies of the Ancients*, ed. by Windle (ib., 1894); Guettard, de Bréau, *The Pygmies*, trans. by S. A. N. York, 1895; Burrows, *The Land of the Pygmies*, with introduction by Stanley (ib., 1898); Brinton, "Dwarf Tribe of the Upper Amazon," in *American Anthropologist* (Washington, 1898); Picard, "Les pygmies," in *Science sociale*, vols. xxvii, xxviii (Paris, 1900); Lloyd, *In Dwarf Land and Cannibal Country* (New York, 1911); Wollaston, *Pygmies and Papuans* (London, 1912); Rawlings, *The Land of New Guinea Pygmies* (Philadelphia, 1913).

DWARF LEMUR. One of four species of small seminocturnal lemurs inhabiting Madagascar, belonging to the genus *Microcebus*. They

live in the highest trees and make a nest of dried leaves, sometimes on a branch or again in a hollow tree. The food consists of fruit and insects, especially butterflies and moths. See CHIROGALE.

DWARF SNAKE. Any of a large variety of

DWARF SNAKE (*Carphophiops vermis*).

(Top, face, and side view.)

small, slender, seclusive serpents, forming the colubrine group Calamariinae, and represented in the warmer parts of the whole world. The typical genus, *Calamaria*, belongs to the East Indies, where these snakes are numerous under logs and in similar hiding places and form a considerable part of the food of other snakes. Several genera and numerous species are to be found in tropical America and Mexico; and one species, *Haldea striatula*, usually included in this group, though considered by Cope a nearer ally of the water snakes (*Natricinae*), is common in the southern United States. It is a pretty little creature, about the size and shape of a lead pencil, brown above and yellow or reddish beneath, with a chestnut band across the head. It hides from view, lives upon insects, and is perfectly harmless. The representatives of the calamarine dwarf snakes in the United States belong to the genus *Carphophiops*, or *Carphophis*, several species of which occur in the warmer half of the country, inhabiting rotten logs and similar hiding places. The general colors are glossy brown above and yellowish or salmon color below. They feed upon earthworms, the pupæ of ants and soft-bodied grubs, and often make their home under half-rotten bark. They are oviparous and deposit a few eggs late in July. The newly hatched young are $3\frac{1}{2}$ inches in length and less than $\frac{1}{2}$ of an inch in diameter.

DWARKA, dwärkä. A town of Baroda state, India, on the Arabian Sea, on the west side of the Kathiawar Peninsula, 270 miles west of Baroda City (Map: India, A 4). It is celebrated as the birthplace and residence of Krishna, to whom the great temple of Dwarakanath is here dedicated. It is a resort for Hindus, over 10,000 pilgrims visiting the shrine annually. Pop., 1901, 7535; 1911, 6548.

DWELSHAUVERS-DERY, dvél'zô'vâr-dä'rê', VICTOR (1836-). A Belgian engineer and physicist, born at Dinant. He was educated at the universities of Brussels and Liège and obtained the chair of engineering at the latter institution in 1869. He was the commissioner of the Belgian government at several international expositions. His writings are devoted chiefly to the regulation of machinery and to the theory of heat engines. He has reduced the modern theory of steam energy to exact figures, basing his calculations largely upon the calorimetric methods of Hirn. His publications include: *Le monde ou nous vivons* (trans. by Anstey, 1871); *Principes de la résistance des matériaux* (1878); *Exposé succinct de la théorie des moteurs à vapeur* (1880-82); *Etude expérimentale thermique de la machine à vapeur* (1892); *Etude expérimentale calorimétrique de la machine à vapeur* (1894).

DWERNICKI, dvr-nits'ké, JOZEF (1779-1857). A Polish general, prominent in the

revolution of 1830-31, born in Warsaw. In 1826 he became a Russian general of brigade. Upon the outbreak of the revolution of 1830-31 he was appointed to organize the Polish cavalry service and on Feb. 14 and 19, 1831, defeated the Russians at Stoczek and Novawicz. He was subsequently taken prisoner by the Austrians and deported to France, where he resided under surveillance. His *Memoirs* were edited by Plagowski (1870).

DWIGHT, BENJAMIN WOODBRIDGE (1816-89). An American educator and author. He was born in New Haven, Conn., and was educated at Hamilton College, New York, and at Yale Theological Seminary, where he graduated in 1838. In 1846 he founded the Congregational church at Joliet, Ill., and, after acting for two years as its pastor, removed to Brooklyn, N. Y., where he established the Dwight High School, which he conducted for 12 years. From 1858 until 1867 he conducted similar schools at Clinton, N. Y., and in New York City. His publications include: *The Higher Christian Education* (1859); *Modern Philology* (1864); *History of the Dwight Family in America* (1874); *Woman's Higher Culture: The True Doctrine of Divine Providence* (1887).

DWIGHT, EDMUND (1780-1849). An American merchant. He was born in Springfield, Mass., and attended Yale in 1799, where he studied law. He practiced at Ames. The firm of Ames, which he established in Boston, was in business at Falls in 1822, Chicopee in 1831, and Holyoke in 1847. Dwight was instrumental with Horace Mann (q.v.) in establishing the Massachusetts State Board of Education and the present normal-school system of the State.

DWIGHT, HARRISON GRAY OTIS (1803-62). An American Congregational missionary. He was born at Conway, Mass., graduated at Hamilton College in 1825, studied theology at Andover, and was afterward sent by the American Board to assist in the Armenian missions. Among his works are: *Christianity Revived in the East* (1850) and a "Catalogue of Armenian Literature in the Middle Ages," in the *Journal of the American Oriental Society* (Boston).

DWIGHT, HENRY OTIS (1843-). An American Congregational missionary, born in Constantinople, Turkey, the son of H. G. O. Dwight. He entered Ohio Wesleyan University, but left in 1861 to serve in the Civil War. He was treasurer of the Northampton (Mass.) Street Railway Company (1866-67) and business agent at Constantinople of the American Board of Commissioners of Foreign Missions (1867-72), edited missionary publications in the Turkish language for seven years, and from 1875 to 1892 was also Constantinople correspondent of the *New York Tribune*. Meanwhile (in 1880) he had been ordained to the ministry. After resigning his commission as a missionary in 1901 he was connected prominently with various missionary and Bible societies in the United States. He edited *Report of the Ecumenical Conference on Foreign Missions* (1900) and the *Encyclopedia of Missions* (1904) and wrote *Turkish Life in War Time* (1881); *Treaty Rights of American Missionaries in Turkey* (1893); *Constantinople and its Problems* (1901); *Blue Book of Missions* (1905; 2d ed., 1907); *A Moslem Sir Galahad* (1913; 2d ed., 1914). He contributed to the *NEW INTERNATIONAL ENCYCLOPEDIA*.

DWIGHT, JOHN SULLIVAN (1813-93). An American music critic, born in Boston, Mass. While at Harvard (class of '32), he aided in founding the Harvard Musical Association, of which he was president for many years. He became a Unitarian minister, but later joined the Brook Farm Community, where he was musical editor of the *Harbinger*. In 1852 he founded *Dwight's Journal of Music*, which he conducted with such ability and consistency of purpose that at one time it enjoyed wide influence. Dwight was, however, a classicist and unable to keep up and sympathize with the tendencies of modern music, especially with Wagner. The *Journal* gradually lost its circulation, and in 1881 it was discontinued.

DWIGHT, JONATHAN, JR. (1858-). An American physician and ornithologist, born in New York City. He graduated from Harvard University in 1880 and from the College of Physicians and Surgeons of Columbia University in 1893. From 1894 to 1904 he was assistant surgeon in the department of laryngology at the Vanderbilt Clinic. In 1886 he became a fellow, and in 1905 treasurer, of the American Ornithologists' Union; and he served as president of the Linnean Society.

DWIGHT, NATHANIEL (1770-1831). An American physician. He was born in Northampton, Mass., and was the brother of the elder Timothy Dwight, president of Yale. He was probably the first to propose the present system of retreats for the insane, and his *Short System of the Treatment of the World* (1795; rev. ed., 1814) was a school geography published in the United States. He also wrote *A Compendious History of the Signers of the Declaration of Independence* (1831).

DWIGHT, SERENO EDWARDS (1786-1850). An American clergyman and writer, a son of President Timothy Dwight, of Yale. He was born at Greenfield Hill, Conn., graduated at Yale in 1803, studied and practiced law, and afterward devoted himself to the study of theology and was pastor of the Park Street Church, Boston, 1817-26. From 1833 to 1835 he was president of Hamilton College. He published the *Life of David Brainerd* (1822); the *Life and Works of Jonathan Edwards* (his great-grandfather) (10 vols., 1830); and a volume entitled *The Hebrew Wife* (1836), written to prove the unlawfulness of marrying a deceased wife's sister. Consult *Select Documents* with a memoir by his brother, William Theodore Dwight (New York, 1851).

DWIGHT, THEODORE (1764-1846). An American lawyer and journalist. He was born at Northampton, Mass., and was the brother of Timothy Dwight, president of Yale, and the grandson of Jonathan Edwards. He was a distinguished lawyer and a leader of the Federalist party, was a member of Congress in 1806-07, and was secretary of the famous Hartford Convention in 1814. His talent as a writer made him a brilliant editor in turn of the *Hartford Mirror*, the *Albany Daily Advertiser*, and the *New York Daily Advertiser*, which he founded in 1817. Among his publications are *Life and Character of Thomas Jefferson* (1839), and a *History of the Hartford Convention* (1833).

DWIGHT, THEODORE (1796-1866). An American author. He was born in Hartford, Conn., the son of Theodore Dwight (1764-1846), graduated at Yale in 1814, and devoted himself to editorial work on various papers and maga-

zines, besides taking an active interest in the work of Sunday schools. Among his publications are: *Tour in Italy* (1821); *The Northern Traveler* (1825; 6th ed., 1841); *First Lessons in Modern Greek* (1833); *The Roman Republic of 1849* (1851); *History of Connecticut* (1841); *The Kansas War: or, the Exploits of Chivalry in the Nineteenth Century* (1859).

DWIGHT, THEODORE WILLIAM (1822-92). An American jurist of distinction. He was born at Catskill, N. Y., graduated at Hamilton College, and afterward studied law at Yale, and was professor of law in Hamilton College, where he established a school of law. In 1858 he was appointed professor of municipal law in Columbia College and became the founder of the law school of that institution and administered it as warden till his resignation in 1891. He was deservedly famous as a law teacher of remarkable lucidity and persuasiveness. In 1868 he became nonresident professor of constitutional law in Cornell University and in 1869 lecturer in Amherst College. He was a member of the New York Constitutional Convention in 1867 and in 1874 became a member of the Commission of Appeals, a court created by act of the Legislature to relieve the congestion of the Court of Appeals; was president of the New York Prison Association; and was an active member of the well-known "Committee of Seventy" of New York City. His publications include *Trial by Impeachment* (1867), *Argument in the Rose Will and Charity Cases* (1863), and papers reprinted from the *American Law Register*, of which he was an associate editor. With Dr. E. C. Wines, the eminent penologist, he also published *Prisons and Reformatories in the United States*, and he edited Maine's *Ancient Law* (New York, 1864).

DWIGHT, TIMOTHY (1752-1817). An American clergyman and educator. He was born at Northampton, Mass., graduated at Yale College in 1769, was a chaplain in the army during the Revolutionary War, pastor and principal of a well-known boys' school at Greenfield, Conn., from 1782 to 1795. In the latter year he was chosen president of Yale College and filled the position till his death, Jan. 11, 1817. His *Travels in New England and New York* (1821) is important for historical purposes. His *Theology Explained and Defended* (1818) is an important work in the development of the New England theology. Consult his memoir by his son, Sereno E. Dwight, in the latter's edition of his *Theology* (New York, 1846).

DWIGHT, TIMOTHY (1828-1916). An American clergyman and educator, born at Norwich, Conn. He graduated at Yale in 1849, studied at Yale Divinity School, and in 1856-58 at the universities of Bonn and Berlin; in 1858 was appointed professor of sacred literature and New Testament Greek and Exegesis in Yale Divinity School, and in 1861 was ordained to the ministry of the Congregational church. In 1886 he was elected president of Yale; his grandfather, Timothy Dwight, had been president of Yale in 1795-1817. He resigned this office in 1899. During his administration Yale took the title of university and assumed proper status as such. He was particularly successful in obtaining the numerous gifts and endowments necessary to an increase in equipment. In 1878-85 he was a member of the American Committee for the Revision of the English Bible. From 1866 to 1874 he was an editor of the *New*

Englander (later the *Yale Review*), in which he published, in 1870-71, a series of articles on "The True Ideal of an American University." He wrote also annotations to the translation of the volumes "Romans," "Philemon," "Timothy-Hebrews," and "James-Jude," in Meyer's *Kommentar zum neuen Testament* (1832 et seq.); a translation of Godet's *Commentaire sur l'évangile de St. Jean* (Paris, 1864-65); an *Address Delivered at the Funeral of President Porter* (1892); a *Commemorative Address* in honor of W. D. Whitney and J. D. Dana (1895), sermons entitled *Thoughts of and for the Inner Life* (1899); *Boston at the Beginning of the 19th Century* (1903); *Memories of Yale Life and Men* (1903).

DWIGHT, WILLIAM BUCK (1833-1906). An American geologist and naturalist, born in Constantinople, the son of Harrison Gray Otis Dwight, the American missionary (q.v.). He came to this country in 1850 and graduated at Yale (1854), Union Theological Seminary (1857), and Sheffield Scientific School (1859). After two years (1865-67) spent in examining West Virginia mines he entered educational work. He was principal of the officers' family school at West Point from 1867 to 1870 and in 1894 was appointed one of the two university examiners for New York State. In 1878 he was appointed professor of natural history and curator of the museum at Vassar College. His most important work as a geologist included investigations of the Cambrian and Ordovician stratigraphy and paleontology, and an exploration of Dutchess Co., N. Y., and the limestone district of the Wappinger valley. He became a frequent contributor to geological papers, but the results of much of his more important paleontological researches are still unpublished. Professor Dwight was editor of the department of geology in the *Standard Dictionary*. He invented the "petrotome," a machine for cutting thin sections of minerals and fossils.

DYAK, or DAYAK. A general name applied by the Malay invaders to the peoples inhabiting the interior and a considerable portion of the coast of the great island of Borneo, who seem to be its aborigines. Physically and linguistically they all belong to the Malayan race, but there are numerous variations from the characteristic type. Dyak culture runs all the way from the savagery of the mountainous interior to the civilization of the coast, where, under Javanese, Bugi, and Chinese influences, the artistic and industrial abilities possessed more or less by all the tribes are seen to better advantage, and many states and sultanates have from time to time flourished. The Dyaks have taken to Islam less kindly than their kindred, the Malays proper, and some of the uncivilized tribes of the interior probably preserve traits of original Malayan heathenism elsewhere lost. Intellectually, morally, and socially the Dyak at his best is perhaps superior to the typical Malay, as he also exceeds him in stature and often in good looks. The Dyaks are also less restrained and more given to physical exercise than the Malays proper. The paddle, the spear, the blow gun, bamboo bridges, cloth weaving, and metal work represent some of the outcroppings of Dyak genius. Among the more savage Dyak tribes are the Olo-out of the central interior; the Punan, farther to the northeast; the Kayans; the Kenyas; the Bahau; Segai, etc. Of these

the Punan (including the Ukits and a few closely allied minor groups) are the only people who do not cultivate rice and do not make boats. They support themselves by hunting and gathering wild jungle fruits. Except for basketry and matting, nearly all their manufactured articles are secured from the other tribes. Thus, they represent the crudest culture of the natives of Borneo. The Milanos about the Redjang River; the Land Dyaks; the Sea Dyaks of Sarawak, Brunei, etc.; the Dusun (Idaan), of the northeast, are all more or less civilized. Some of the Dyaks take well to agriculture, and head hunting and cannibalism, for which the Dyaks were once so famous, are rapidly disappearing. The traditional home of the Dyaks is in the mountains of the central interior, from which the so-called "Sea Dyaks," once famous as pirates, have wandered farthest. The results of the Haddon exploring expedition of 1898-99 have added much to our knowledge of the tribes of the interior. Besides the general works on Borneo, consult: Bock, *Head Hunters of Borneo* (London, 1881); Klein, *Die bildenden Künste bei den Dayaks auf Borneo* (Vienna, 1890); Roth, *The Natives of Sarawak and British North Borneo* (London, 1896); W. H. Furness, *The Home Life of Borneo Head-hunters* (3d ed., Philadelphia, 1902); Edwin H. Gomes, *Seventeen Years among the Sea Dyaks of Borneo* (Philadelphia, 1911); A. W. Nieuwenhuis, *Quer durch Borneo* (2 vols., Leiden, 1904); Hose and McDougall, *The Pagan Tribes of Borneo* (2 vols., London, 1912).

DYAS. See PERMIAN SYSTEM.

DYAS, ADA (?-1908). An Irish actress, both of whose parents were on the stage. She made her London début in 1861 in *Henry IV*. She created the part of Phœbe in Robert's *Lady Audley's Secret* and that of Clara in *Hunted Down* (1866), and she was selected by Wilkie Collins himself to play the double rôle of Anne and Laura in *The Woman in White* (1870). Her first American appearance was under the management of Augustin Daly in 1872 at the Fifth Avenue Theatre, New York, in *Man and Wife*. Later, at Wallack's, her most successful rôles were those of Kate Harcastle, Lady Teazle, Lady Gay Spanker, Lydia Languish, and especially that of Claire Ffolliott in Boucicault's *The Shaughraun*. She toured as Esther Eccles in *Caste* and subsequently as Mrs. Ralston in *Jim the Penman* and as Mrs. Seabrooke in *Captain Swift*. In 1892 she played Goneril in Sir Henry Irving's revival of *King Lear* at the London Lyceum.

DYCE, ALEXANDER (1798-1869). An English scholar and critic, born in Edinburgh. He was educated at the high school of that city, and at Exeter College, Oxford. After officiating for some time as curate, he settled in London in 1825. His literary reputation is chiefly based on his editions of the older English poets and authors—George Peckle, Robert Greene, John Webster, Shirley, Thomas Middleton, John Skelton, Beaumont and Fletcher, Ford and Marlowe, with biographies of the authors and instructive notices. He also edited the poems of Shakespeare, Pope, Akenside, and Beattie, for Pickering's Aldine Edition of the Poets. Two old plays discovered by him, called *Timon* and *Sir Thomas More*, were published by the Shakespeare Society. In conjunction with Collier, Halliwell, and Wright, he founded the Percy Society for the publication of old English ballads.

lads, plays, and poems. His ability as a commentator on Shakespeare is proved by his *Complete Edition of the Works of Shakespeare; the Text Revised; with Account of the Life, Plays, and Editions of Shakespeare, Notes, etc.* (1857). The *Glossary* to this edition, in its day the best and largest—a volume of 500 pages—was issued (New York, 1902) as *General Glossary to Shakespeare's Works*.

DYCE, WILLIAM (1806–64). A Scottish historical painter. He was born in Aberdeen, Sept. 19, 1806, the son of a distinguished physician. At the age of 16 he graduated from Aberdeen University with the degree of M.A. and went to London to study painting at the Royal Academy. He made two visits to Rome, in 1825 and in 1827, and during the second developed strong Pre-Raphaelite tendencies, his work meeting with the enthusiastic approval of Overbeck and the Nazarene painters. Not finding his Madonnas appreciated on his return to Aberdeen, he devoted himself to scientific pursuits and afterward to portrait painting, in which he succeeded especially well with women and children. He settled in London in 1830 and was made associate of the Royal Academy in 1835. His pamphlet upon the application of design to manufactures, in 1837, led to his appointment as superintendent of the School of Design, then recently established at Somerset House, London, and the publication of his report upon French and German schools of applied art, in 1840, resulted in the reorganization of the London school and the establishment of provincial schools in accordance with his ideas. In 1844 he was made professor of fine arts in King's College, London, and in 1848 a member of the Royal Academy.

In the competition for the frescoes of the new Houses of Parliament, held in 1844, Dyce was one of the successful competitors. His "Baptism of Ethelbert," in the House of Lords, was deemed so successful that the other artists were instructed to adapt their design and coloring to his. He executed for the Prince Consort, at Osborne, an impressive fresco, "Neptune Giving the Empire of the Sea to Britannia," and was intrusted with the decoration of the Queen's robing room at Westminster. The subjects, which he himself had suggested, were from the legend of King Arthur, typifying "Chivalry," and the five which he lived to finish are his masterpieces. He died in London, Feb. 14, 1864.

Dyce's art represents a revolt from the eclectic principle of the Academy, similar to that more definitely inaugurated at a later period by the Pre-Raphaelites. It is refined and tasteful, but rather a learned art than one which appeals strongly to the senses. It resembles that of the German Nazarenes, except that the color is better. Besides the frescoes mentioned above, among his chief paintings are "Bacchus Nursed by the Nymph" (1827); "Joash Shooting the Arrow of Deliverance" (1844); "Madonna and Child" (1846, Royal Academy); "Meeting of Jacob and Rachel" (1850, Hamburg Kunsthalle). He also designed some fine cartoons for stained-glass windows in Ely Cathedral and other churches. The National Gallery of Scotland contains a number of his pictures. He was deeply learned in theology and patristic literature and one of the leaders of the "High Church Movement." He was also a fine organist and the composer of anthems. For a publication of the Book of Common Prayer, set to the

ancient music, he received the Prussian gold medal of science and art. He also published numerous pamphlets on art.

Consult the article "William Dyce," in the *Dictionary of National Biography* (London, 1888), and in Redgrave, *Dictionary of Artists in the English School* (ib., 1878).

DYCK, dik, VAN. See VAN DYCK.

DYEA, də'a or dī'a (American Indian, pack, load). Formerly a village in the southern district of Alaska, on Chilkoot Inlet, the east fork of Lynn Canal (Map: Alaska, N 6), and at one time important as a starting point for the upper Yukon and the gold fields of the Klondike; but it has been outstripped by Skagway (q.v.), owing to the opening of the White Pass and Yukon Railroad. The Dyea, or Chilkoot, route began at Dyea.

DYEING (OF. *dyeen*, to dye, AS. *dēagian*, from *dēag*, color; connected with AS. *dēaw*, dew). The art by which various substances, especially textile fibres, are impregnated with coloring matters with sufficient tenacity to resist the action of light, water, or ordinary wear.

History. The art of dyeing was practiced in some form by all ancient peoples. It is mentioned in the Bible that Jacob gave his favorite son Joseph a coat of many colors, and Moses tells how the skins of the ram and the badger used in the tabernacle were dyed red. The so-called Tyrian purple was known in the early days of the Roman Empire. It was such an expensive dye that the Emperor and the Imperial family were practically the only users of it, which gave rise to the expression "born to the purple." By an edict of the Emperor Diocletian, issued 301 A.D., the price of wool well dyed with this color was fixed at the equivalent of \$350 in gold per pound. According to Pliny, the purple color was derived from certain shellfish, a species of snail, found along the coast of Phoenicia. In time the shellfish became almost exterminated, and by the Middle Ages the dye had been lost to commerce. Recently a German color chemist, Dr. Friedländer, collected a sufficient number of the shellfish, which are still to be found along the shores of the Mediterranean, to extract the coloring matter and analyze it. It proved to be a combination of indigo and bromine. Neither the natural color nor its synthetic reproduction is of present-day importance. Pliny is also the authority for the statement that methods of dyeing black, yellow, and green were brought into Greece from India on the return of Alexander the Great. Some dyes probably of Indian origin are indigo, similar to the wood which Julius Cæsar found in use among the Britons; turmeric, or Indian saffron; cutch; and gambier. Towards the close of the Middle Ages the art of dyeing was greatly developed in northern Italy, especially in Florence, where the dyestuff archil (q.v.) was discovered about 1300. The early voyagers to America brought back with them new and valuable dyestuffs, such as cochineal, logwood, quercitron, and fustic. Subsequently dyeing developed according to the discoveries of new dyestuffs such as the mineral dyes, and the application of improved processes until 1856, when the first artificial dyestuff, mauve, was discovered by William Henry Perkin in experimenting with aniline. Many aniline colors and other coal-tar dyes followed, until now dyes of this class have almost entirely superseded the natural dyestuffs. (See COAL-TAR COLORS.) The

NATURAL DYESTUFFS	ARTIFICIAL DYESTUFFS THAT HAVE DISPLACED THE NATURAL ONES FOR COTTON	ARTIFICIAL DYESTUFFS THAT HAVE DISPLACED THE NATURAL ONES FOR WOOL AND SILK
Quercitron (Still used along with logwood for printing).	Diamine fast yellow, B. A. (C.), Chloramine yellow (C.), Chrysophenine (C.), Auramine (H. G.), Diamine yellow (H.), Chrysinamine (H.), Thioflavine (G.).	The different shades of yellow; also, Naphthol yellow (H.).
Persian Berries (Still much used in cotton printing and with tin salts, but little for wool).	For direct printing, Auramine, Thioflavine, T. (C), the latter exclusively for discharges; also, Chloramine yellow; important are also Diamine yellow (H.).	For silk: Tartrazine, Fulling yellow (C.), Naphthol yellow, S. (H.).
Weld		Naphthol yellow, S., Fast yellow (C), Tartrazine, Fulling yellow (C.), Citronine (G.), Jasmine (G.), Azoyellow (H.), Fast yellow (H.), Alizarin yellow (H.).
Fustic (Still used for printing in connection with logwood and for dyeing wool).	Same as for Quercitron; also: Sun yellow (G.), Diphenyl fast yellow (G.), Cresotin yellow (G.), further, Alizarin yellow and its homologues (H.).	Anthracene yellow (C. G.), Chrome yellow (C. G.), Morant yellow (C. G.), Pulling yellow (C.), Azoyellow (H.), Fast yellow (H.), Alizarin yellow (H.).
Logwood (Still used as extensively as before, for silk).	Aniline black, Diamine black (C.), Columbian black (C.), Vidal black, and similar sulphated products.	Naphthol and Naphthylamine black (C. G. H.), Diamine black (C. G.), Diamond black (C. G.), Anthracene black (C. G.), Alizarin black (G. H.), Chromotrope, S. (H.).
Brazilwood	Diamine fast red, F. (C.), Congorubin (C.), Diamine bordeaux (C.), Diamine red (G. H.), Fu... Hessian purple (G.), Safran... amtranline red (H.), Alizarin red (H.).	Cloth red (C.), Wool red (C.), Acid fuchsin (G.), Fast red (H.), Archil substitute (G.), Ponceau (H.), Apollo red (G.), Rocellin (G.); in the fulling industry, Alizarin red (C. H.), Diamine fast red (C.), Chromotrope (H.).
Cochineal (Still used to some extent).		Vivid acid wool colors such as Azorubine (G.), Chromazon red (G.), Brilliant cochineal (C.); and the different Ponceaux, etc.
Archil (Almost entirely displaced).		Acid fuchsin (C.), Azorubine (C. G. H.), Archil... H.), Azofuchsin (C. G. H.), Azorubin (C.), Azoacid... Rosindulin (G.), Apollo red (G.), Chromotrope (H.).
Annatto	Orange colors, as Chrysophenine (H.), Minkado yellow and orange (H.).	
Safflower	Rhodamine (C. G.), Erica (C.), Diamine rose (C.), Geranine (C.), Safranine (H.), etc.	
Berberin (Still used to some extent for dyeing silk).		Same as for WELD.
Catechu (Still much used, especially in combination with logwood, for silk).	Diamine colors, Benzo and Congo colors with supplementary treatment with chrome and copper, recently computed successfully (C.) and Chrysoidin (H.), Resurin (H.) etc. Alizarin colors (partly in calico printing).	
Indigo	Synthetic indigo, Indoin (C. G. H.), Naphthindon (C.), Fast cotton blue (C.), Methylen blue (C. H.), Indamine blue (H.), Janus blue (H.), ... zable blue ... related colors (H.), Diaminogen blue, C. H., A new product, Immedial blue (C. H.), belonging to the sulphated colors, seems to be among the most important substitutes. In calico printing natural indigo has been in part replaced by the Synthetic Indigo preparations and by the different basic blues including Nitroso blue, Alizarin blue, etc. (C.).	Alizarin blue (C. G. H.), Synthetic indigo, Alizarin cyanin (C. G. H.), Anthracene blue (G. H.), Chromotrope, F. B. (H.), Gallamate blue (G.), Gallocyanin (G.), Sulphocyanin (C.), Lanacyl blue.

most important natural and artificial coloring matters may be found described in articles under their special names. Mineral and artificial dyes were formerly considered more the artificial ones, but this view has in most cases positively no foundation in fact. The accompanying table shows which artificial substances are partly or completely displaced natural ones in the dyeing of animal and vegetable fibres.

Dyestuffs may be divided into "basic colors," which dye vegetable fibres only after the use of an acid mordant, and "acid dyes," which require basic mordants for the same fibres. Both classes dye animal fibres direct without a mordant. A newer class known as "substantive dyes" can be used with both vegetable and animal fibres without mordant. Most of the older aniline dyes belong to the first class; alizarine and sulphurated dyes to the second class; the newer azo dyes to the third class. (See *Azo Colors*, under the article COAL-TAR COLORS.) Based on their methods of application, most of the dyestuffs used at the present time fall into the following classes: acid, basic, substantive, mordant, after-chromed, developed, naphthol, coupled, sulphur, indigo or vat, oxidized, and mineral pigment dyes.

Mordants. These are substances capable of combining with other substances (the commercial dyestuffs) to form insoluble colored compounds. Thus, aluminum salts make an insoluble red compound with alizarin and are therefore used as mordants in calico printing. Ferric salts make, with alizarin, an insoluble dark purple compound and are likewise employed as mordants in calico printing. Soluble mordant salts must themselves be transformed into insoluble compounds before they are allowed to form the dyes in order to prevent the mordanting material from being dissolved out of the fabric when the latter is introduced into the dye bath. Therefore, after the fabric has become impregnated with the soluble mordant salt, it is treated with ammonia, lime, or hot steam—with a view to transforming the soluble salt into an insoluble hydroxide or an insoluble basic salt; or else the fabric is treated with sodium phosphate or sodium arsenate—with a view to transforming the soluble salt into an insoluble phosphate or arsenate. In the case of animal fibres the same end is often attained by simply immersing the fabric in a boiling dilute solution of the soluble salt, the insoluble mordant being then deposited in the fibre directly. The fabric containing the insoluble mordant is ready to be treated with the dyeing substance, the resulting color of the fabric being evidently that of the compound formed by the latter with the mordant. Another method of dyeing with the aid of mordants, extensively employed in calico printing, consists in mixing the dye directly with the soluble form of the mordant and with starch, dextrin, gum, or some other thickening substance, printing the mixture on the fabric, and then subjecting the latter to a process of steaming. The result is of course the same as in case the other methods are employed; for the steaming process has the effect of transforming the soluble into an insoluble form of the mordant, the latter then combining with the dyeing substance. Mordants may be either basic or acid—the former combining with "acid dyes," the latter with "basic dyes." The mordants mentioned above are

basic, and their compounds with dyes are termed "lakes." Among the acid mordants may be mentioned tannin, or tannic acid. After the fibre has been impregnated with this mordant in its ordinary, soluble form, it is passed through a weak solution of chloride of tin or of tartar emetic. These produce respectively the tannate of tin or the tannate of antimony (tartar emetic is a compound of antimony), and these insoluble tannates further combine into insoluble colored compounds with dyes.

Theories of Dyeing. The question as to whether dyeing involves true chemical combination of the fibres with the dyestuffs or not has not yet been definitely answered. Some investigators believe that dyed fibres are merely mechanical mixtures; others hold that dyed fibres are true chemical compounds; finally, still others hold that they constitute what are now termed "physical mixtures," or "solid solutions." Those who accept the chemical theory argue that if the dyestuff did not combine chemically with the fibre, then there would be no reason why chemically neutral-colored substances should not act as dyes; yet true dyes are generally either acid or basic, while the fibres themselves may be either basic or acid, or else may include both basic and acid constituents. In support of the chemical theory is the fact that some substances, while themselves colorless, are capable of coloring fabrics when directly applied, the view being that colored substances must be transformed chemically in order to produce color. The principal arguments in favor of the "physical mixture" theory, advanced by O. N. Witt in 1890, are as follows: 1. Solid fuchsin is green, with a metallic lustre; solutions of fuchsin are colored red; and fabrics dyed with fuchsin are likewise colored red. 2. Solid rhodamine shows no trace of fluorescence; its solutions are fluorescent; and silk dyed with rhodamine likewise shows distinct fluorescence. The fact that the same dyestuff may impart different colors to different fabrics is compared with the fact that iodine gives different colors in different solvents, and yet there is no reason for assuming that iodine forms chemical compounds with its ordinary solvents. Finally, in accordance with Witt's theory, the function of mordants is explained by the assumption that solutions of these substances in fibres are much better solvents for the dyestuffs than are the pure fibres. However, while interesting because capable of development and quantitative verification, this physicochemical theory is yet far from being definitely established or generally accepted by chemists.

Dyeing Processes. Cotton, silk, artificial silk, and wool are the textile fibres that are subjected to processes of dyeing. Before being dyed, fibres are first cleaned so as to remove all natural and artificial impurities such as grease and dirt, which tend to produce spots or uneven shades of color, in consequence of improper fixing of the mordant and color. Whenever light and delicate tints are to be dyed on the fibre, bleaching becomes necessary. The preliminary steps in the preparation of cotton include boiling the fibre in a weak solution of caustic lye, after which it is rinsed and then steeped in a solution of bleaching powder and again rinsed. A further step consists in steeping it in dilute sulphuric, hydro-

chloric, or acetic acid, after which it is again cleansed by washing, and dried. Silk is boiled in soap solution in order to remove the natural silk glue which accompanies the crude fibre and is then bleached either by exposure to sulphurous acid fumes produced by burning sulphur or by the use of the peroxides of hydrogen and sodium. Wool is cleansed by washing in warm soap solution, frequently combined with sodium or ammonium carbonate, by means of which the natural grease of the fibre is removed. It is then bleached with sulphur dioxide.

Apparatus. The apparatus of the dyer is very simple, consisting of vats, kettles, and cisterns, which may be of wood, stone, or metal. In Europe the kettles are still heated over open fires, but in America a steam coil is universally used. A pure water supply is absolutely essential to successful dyeing. When the available water supply is contaminated by sewage or the water is hard because of lime salts, artificial purification must be employed. Suspended matter may sometimes be removed by sedimentation or filtration, or the two combined, but chemical treatment may be required to remove these and other impurities.

Dyeing may be done in various stages of fabric manufacture, depending upon the material and the purpose for which it is intended. Some of the methods employed are:

1. *Raw-Stock Dyeing.*—This is also known as dyeing in the wool. The wool is dyed after scouring, and after bleaching if the latter is necessary, but before it is carded or spun. The dye penetrates the fibre well, giving a permanency of color desirable in garments destined for hard wear. In the Oxford mixture the black is generally dyed in the wool.

2. *Dyeing in the Slub.*—The slub, or top, is the soft rope of fibres formed in the process preparatory to twisting and spinning. Dyestuffs penetrate it readily. A special machine is in use which prints the dye upon the slub at regular or irregular intervals. Later drawing and twisting give a well-mixed effect to the yarn. Such yarns are used for the Vigoureux mixture.

3. *Skein Dyeing.*—The yarn is dyed in the skein. Gingham and woollen plaids are skein dyed.

4. *Piece Dyeing.*—The material is dyed after weaving.

5. *Cross Dyeing.*—This method is applied to wool and cotton mixtures. Dyes are used for wool which are fugitive on cotton; therefore the wool takes the dye, and the cotton remains unchanged. White hair-line or check effects are produced in this way. If a single color is desired, the cotton is dyed first to the right shade, then the material brought up to uniform color in a wool bath.

6. *Resist Dyeing.*—This is a form of cross dyeing. Certain yarns, or parts of fabrics, are treated to resist the dye which colors the remainder of the material. The Javanese employ this method in their Batik work.

7. *Discharge Dyeing.*—By the use of chemicals the color is discharged from dyed material, in polka dot or other pattern effects.

In all dyeing operations considerable attention must be paid to the permanency of the dye used. Dyes may be fast to light, to washing, or to both. The choice of dyestuff as to fastness is determined by the purposed use of

the material to be dyed. A color is considered fast to light if it does not fade with four weeks' exposure to the sun; moderately fast if only a slight fading is observed after three weeks, and fugitive if it fades in one week.

Bibliography. The literature of dyeing is very extensive, and reference should be had to the articles in the various technical cyclopædias as well as to the following works: Crookes, *A Practical Handbook of Dyeing and Calico-Printing* (London, 1874); Hurst, *Silk Dyeing, Printing, and Finishing* (Glasgow, 1892); Knecht, Rawson, and Lowenthal, *A Manual of Dyeing, for the Use of Practical Dyers, Manufacturers, Students, and All Interested in the Art of Dyeing* (London, 1893); Fraps, *Principles of Dyeing* (New York, 1903); Dyer and Color-Maker's Companion (Philadelphia, 1898); *Recent Progress in the Industries of Dyeing and Calico-Printing*, being a supplement to Sansone, *The Printing of Cotton Fabrics* (Manchester, 1895); id., *Dyeing* (ib., 1897); Sadtler, *Industrial Organic Chemistry* (Philadelphia, 1900); Cain and Thorpe, *The Synthetic Dye Stuffs* (London, 1905); Pellaw, *Dyes and Dyeing* (New York, 1913); Matthews, *Laboratory Manual of Dyeing and Textile Chemistry* (ib., 1913); and Yearbooks issued by the various color houses. See TEXTILE PRINTING; COAL-TAR COLORS; MINERAL COLORS; MORDANTS; and special articles on dyestuffs.

DYER, ALEXANDER BRYDIE (1817-74). An American soldier. He was born in Richmond, Va., graduated at West Point in 1837, and was assigned to the Third United States Artillery. He served in the Florida War in 1837-38 and as lieutenant of ordnance in the war with Mexico in 1846-48, being brevetted captain for gallant conduct. At the beginning of the Civil War he did much to increase the efficiency of the Ordnance Department and in 1864 was appointed chief of ordnance at Washington, with the rank of brigadier general—a position which he held until his death. From 1861 to 1864 he had charge of the Springfield (Mass.) armory and in 1865 was brevetted major general in the regular army.

DYER, ELIPHALET (1721-1807). An American legislator and soldier. He was born at Wethersfield, Conn., graduated at Yale in 1740; and was admitted to the bar in 1746. He held several Colonial offices, originated the plan of establishing a Connecticut colony in the Susquehanna valley, and was sent to England in 1763 as the agent of the Susquehanna Land Company. He was lieutenant colonel of a Connecticut regiment in the French and Indian War, was the first commissioner sent by Connecticut to the Stamp Act Congress in 1765, and was a member of every Continental Congress excepting those of 1776 and 1779. From 1776 to 1793 he was a judge of the Superior Court and for the last four years was Chief Justice.

DYER, GEORGE (1755-1841). A prolific writer, inveterate student, and amiable eccentric, who will live at least in Lamb's letters and in his essay, "Amicus Redivivus," where Dyer's absent-minded and well-nigh fatal plunge into the New River is described with gentle humor. Born a poor boy, he found friends who helped him to an education at Christ's Hospital and Cambridge (Emmanuel College). He became an insatiable bibliographer, and he wrote notably: *Poems* (London, 1792); *Poems and*

Critical Essays (ib., 1802); *History of the University and Colleges of Cambridge* (2 vols., ib., 1814); *Privileges of the University of Cambridge* (ib., 1824). His editorial labors over Valpy's 141-volume edition of the classics were so excessive as to induce total blindness.

DYER, HENRY (1848-). A Scottish engineer and educator. He studied at Anderson's College (later called Glasgow and West of Scotland Technical College) and at Glasgow University. In 1873 he was chosen principal and professor of civil and mechanical engineering in the newly founded Japanese Imperial College of Engineering. He lived in Japan for 10 years, teaching and directing large engineering projects. Upon his return to Glasgow he took an active part in movements for social and educational reform, writing especially on industrial education. He published: *The Evolution of Industry* (1895); *Dai Nippon: The Britain of the East* (1904); *Japan in World Politics* (1909).

DYER, ISADORE (1865-). An American physician, born at Galveston, Tex. He graduated from Sheffield Scientific School (Yale) in 1887, studied at the University of Virginia, and took his M.D. in 1889 at Tulane University, where, after three years as interne and lecturer in New York, he served in various capacities, becoming professor of diseases of the skin and dean of the medical department in 1908. He also actively identified himself with the work of New Orleans hospitals and with the care of lepers, in 1894 founding the Louisiana Leper Home. In 1908 he was appointed a lieutenant in the United States Army Medical Reserve Corps. He was vice president of the American Medical Association (1903) and of the New York Medico-Legal Society (1908-10), and president of the Louisiana State Medical Society (1902-03) and of the Southern Medical Association (1910-11). In 1896 he became editor of the *New Orleans Medical and Surgical Journal*, and he is also author of articles in various medical text and reference books.

DYER, JOHN (c.1700-58). An English poet, born at Aberglasney, Carmarthenshire, Wales. He took up the study of poetry in pursuit of his art wandered in Wales and the English counties. After studying art in Italy he returned to England, took orders, and held several livings. His writings include chiefly: *Grongar Hill* (1727), still found in many anthologies; *The Ruins of Rome* (1740), of which Johnson well remarks that "the title raises greater expectation than the performance justifies"; *The Fleece* (1757), referred to by Wordsworth in his sonnet "To the Poet, John Dyer."

DYER, LOUIS (1851-1908). An American educator and author, born in Chicago, Ill. He graduated at Harvard in 1874, and at Balliol College, Oxford, in 1878, and was assistant professor of Greek at Harvard from 1881-87. In 1889 he was a lecturer at Balliol College, Oxford. He was acting professor of Greek in Cornell University, and in 1896 a lecturer before the Royal Institution. In 1900 he gave at the University of California a series of lectures which was repeated at many colleges and universities. His publications include: a translation of Cossa's *Introduction to the Study of Political Economy* (1893); *The Greek Question and Answer* (1884); *Studies of the Gods in Greece*

(1891); *Oxford as it is* (1902); *Machiavelli and the Modern State* (1904).

DYER, or DYAR, MARY (?-1660). One of the victims of the persecution of the Quakers in early Massachusetts. She and her husband, William Dyer, a milliner, emigrated from London to Boston, Mass., in 1635, but in 1638, owing to their support of Anne Hutchinson in the Antinomian controversy, were forced to remove to Rhode Island. She spent the years 1652-57 in England, where she was converted to Quakerism, and in 1658 was expelled from the Colony of New Haven for preaching Quaker doctrines. In September, 1659, she was arrested and imprisoned in Boston, whither she had gone to visit three Quakers who had already been thrown into prison, and soon afterward she was banished with the others on pain of death should she remain in the Colony or return to it. In October she returned to Boston and was promptly sentenced to death, but was reprieved after being forced to witness the hanging of two other Quakers, Robinson and Stephenson. In May, 1660, she again visited Boston, was again condemned to death by Governor Endecott for "rebellious seditious and obtruding herself after banishment upon pain of death," and this time was publicly executed by hanging on Boston Common, June 1, 1660. Consult Rogers, *Mary Dyer, the Quaker Martyr* (Providence, 1896), and Jones, *The Quakers in the American Colonies* (New York, 1911).

DYER, NEHEMIAH MAYO (1839-1910). An American naval officer, born at Provincetown, Mass. He volunteered in the army in 1861; but was transferred to the navy, in 1864 was promoted to be acting master and placed in command of the *Randolph*, in 1868 became lieutenant commander and in 1883 commander. Promoted to be captain in 1897, he commanded the protected cruiser *Baltimore* in the battle of Manila Bay, May 1, 1898. In 1901 he received the rank of rear admiral and was retired. He was chairman of the commissioners of the Massachusetts Nautical Training School in 1903-04.

DYER, THOMAS HENRY (1804-88). An English historian, born in London. In 1841 he published his *Tentamina Æschylea*, the result of his studies in the emendation and restoration of passages. Most important among his works are: *Life of Calvin* (1850); *History of Modern Europe* (4 vols., 1861-64; 2d ed., revised and enlarged, 5 vols., 1877); *The History of the Kings of Rome* (1868). His *History of the City of Rome* (1865) was the first connected narrative on that subject, and his *Pompeii: Its History, Buildings, and Antiquities* (1867) contained a careful description of the remains so far as known up to that time. His works were scholarly, drawn from authentic sources, and clear in their structure.

DYER, SIR WILLIAM TURNER THISTLETON (1843-). An English botanist. He was born at Westminster and was educated at King's College, London, at Oxford, and at Göttingen. He became professor of natural history at the Royal Agricultural College, Cirencester, in 1868, and professor of botany at the Royal College of Science for Ireland in 1870. From 1885 to 1905 he was director of the Royal Gardens at Kew. He was a fellow of the University of London from 1887 to 1890, Royal Commissioner to the Paris International Exhibition (1900) and to the St. Louis Exposition (1904), botanical adviser to the Secretary of State for

the Colonies (1902-06), and became a member of the court of the University of Bristol in 1909. His principal works are an English edition of Sach's *Text-Book of Botany* (1875), editions of the *Flora Capensis* and of the *Flora of Tropical Africa*, and *Index Kewensis* (1905). With Trimen he published *The Flora of Middlesex* (1869).

DYER'S BROOM (*dyer* + *broom*, plant), DYER'S GREEN WEED, or WOADWAXEN (*Genista tinctoria*). A perennial shrub of European origin, bearing small yellow flowers and simple leaves, and said to be the bush Genet, from which the Plantagenet family took its name. In Europe its tops were formerly used for a yellow dye. It was extensively cultivated in New England and has escaped and become established in portions of New York and Massachusetts.

DYERSBURG. A city and the county seat of Dyer Co., Tenn., 77 miles north-northeast of Memphis, on the Illinois Central, the Birmingham and Northwestern, and the Chicago, Memphis, and Gulf railroads, and on the Forked Deer River, at the head of navigation (Map: Tennessee, A 2). It is in a fertile agricultural region, producing cotton, wheat, and corn, and has cotton gins, a compress, a cottonseed-oil mill, saw, planing, and flour mills, wagon factories, a grain elevator, pressed brick, tile, and stave and heading factories, a tobacco factory, a foundry, a machine shop, a wooden-bowl factory, etc. The water works, sewage system, and electric-light plant are owned by the municipality. Pop., 1890, 2009; 1900, 3647; 1910, 4149.

DYER'S ROCKET, or DYER'S WEED. See WELD.

DYES, DYEING. See COAL-TAR COLORS.

DYESTUFFS. See ANIMAL COLORS; COAL-TAR COLORS; MINERAL COLORS; VEGETABLE COLORS; DYEING; TEXTILE PRINTING.

DYING DECLARATION. See DECLARATION, DYING.

DYING GAUL. A famous statue, probably a Greek original, in the Capitoline Museum, Rome. It was formerly erroneously called "The Dying Gladiator" and was beautifully described as such by Byron in *Childe Harold's Pilgrimage*. In reality, it represents a dying Galatian and belongs to one of two groups dedicated respectively at Pergamum and Athens by Attalus I, King of Pergamum, to commemorate his victory over the Galatian tribes who invaded Asia Minor in the second century B.C. In this statue a tragic idea is expressed with powerful realism and remarkable technique.

DYKE. See DIKE.

DYKES, JAMES OSWALD (1835-1912). A Scottish Presbyterian clergyman and educator, born at Port Glasgow. He studied at the universities of Edinburgh, Heidelberg, and Erlangen, was ordained to the Presbyterian ministry in 1859, and in 1861 became copastor with Dr. Candlish of Free St. George's Church, Edinburgh. In 1869 he was appointed pastor of the Regent Square Church, London, and in 1888 principal of the Theological College of the Presbyterian church of England. His publications include: *From Jerusalem to Antioch* (1875); *The Law of the Ten Words* (1884); *The Gospel According to St. Paul* (1888); *Plain Words on Great Themes* (1892); *The Christian Minister and his Duties* (1908); *The Divine Worker in Creation and Providence* (1909).

DYLISK. See DULSE.

DYMOND, JONATHAN (1796-1828). An

English writer. He was a member of the Society of Friends and was prominent as an expositor of the principles of his sect. In 1823 he published anonymously an *Inquiry into the Accordance of War with the Principles of Christianity*, which attracted wide attention. His chief work is his *Essays on the Principles of Morality* (1831), which is devoted to the application of moral principles and attacks war and slavery.

DYMOV, OSIP (the pseudonym of OSIP ISIDOROVITCH PERELMAN) (1878-). A popular Russian writer. He was born at Bialostock, but removed to the United States and settled in New York. His short stories and plays, some of them dealing with Jewish life, are of considerable merit. He excels, however, in his briefer sketches and parodies, which are full of humor. A collection of his humorous stories appeared in 1910 under the title *Merry Melancholy*. His plays include *Cain* (1906), *Hear Israel* (1907), *Every Day* (1908), and *The Eternal Wanderer* (1913).

DYNAMETER (contracted from *dynamometer*, from Gk. *dύναμις*, *dynamis*, power + *μέτρον*, *metron*, measure). An instrument for measuring the magnifying power of a telescope. The power of a telescope is found by dividing the focal length of the object glass by the focal length of the eyepiece; which quotient equals that obtained by dividing the diameter of the object glass by the diameter of its range formed at the focus, and seen through the eyepiece. The object of the dynameter is to measure the diameter of this image. Practically the magnifying power may be measured as follows: The telescope is directed to the daylight sky. A small, round, bright spot is then seen on looking at the end of the eyepiece. This spot is an image of the object glass. The diameter of the spot is measured with a dynameter, or any micrometric instrument capable of measuring small objects accurately. The object glass being then also measured, a simple division of the object-glass diameter in inches by the diameter of the spot, also in inches, gives the magnifying power.

DYNAMICS (Gk. *δυναμικός*, *dynamikós*, powerful, from *δύναμις*, *dynamis*, power, from *δύνασθαι*, *dynasthai*, to be able). That branch of mechanics (q.v.) which treats of the motion of matter. It embraces the discussion of the conditions under which the motion of matter is changed and the mathematical properties of this motion. Dynamics is sometimes divided into the two great subjects *statics* and *kinetics*, statics being the discussion of conditions under which there is no change in the motion; kinetics, those under which there is change. Dynamics of a "particle" treats the motion of a geometrical point endowed with mass. "Rigid" dynamics treats the motion of large, rigid bodies; i.e., those made up of particles so connected that they have no relative motion.

DYNAMIC UNITS. See MECHANICAL UNITS.

DYNAMITE (from Gk. *δύναμις*, *dynamis*, power). Any explosive substance consisting of nitroglycerin and an absorbent which is fired by detonation, is styled dynamite. The original one, consisting of nitroglycerin and an absorbent such as infusorial earth (*Kieselguhr*) or diatomaceous silica, tripoli, rotten stone, etc., was invented in 1866 by Alfred Nobel. The quantity of nitroglycerin in their mixtures varies from 75 per cent down to 30 per cent of nitro-

glycerin, but 40 per cent of nitroglycerin is given as the average amount. Nobel also made use of gunpowder as an absorbent. In the United States the absorbent often is an aid to combustion, and consists of a mixture of wood pulp and sodium nitrate, with small quantities of magnesium or sodium carbonate to neutralize any acid which may be present in the mixture. The product when thus formed is known as a straight dynamite, but nitrates, charcoal, and wood fibre may be used for the absorbing material. Perhaps the most powerful form of dynamite is the explosive or blasting gelatin also invented by Nobel, in 1875, where pyroxilin or soluble cellulose nitrate is dissolved in water and a jelly-like mass produced. When this material is mixed with wood pulp and potassium nitrate, the resulting product is known as gelatin dynamite. We have therefore dynamites with an inert base and dynamites with an explosive base or dope.

When ammonium nitrate is used in the composition, we have ammonia dynamites. When di- and tri-nitroglycerin or nitrochlorhydrin or nitrosubstitution compounds are put in the dope, we have so-called L. F. (low-freezing) dynamite. For commercial use the dynamite is usually made up in sticks or cartridges 8 inches in length and 1 to 3 inches in diameter, which are packed in sawdust or cartons in cases containing 50 pounds each. See EXPLOSIVES; NITROGLYCERIN.

The United States census gives statistics for the production of dynamite in the United States as follows:

YEAR	PRODUCTS	
	Pounds	Value
1880.....	30,626,738	\$622,671
1890.....	30,626,738	4,253,032
1900.....	85,846,456	8,247,223
1904.....	130,920,829	12,900,193
1909.....	195,155,851	18,699,764

DYNAMITE CRUISER. See ORDNANCE, *Classes of Cannon.*

DYNAMITE FARMING. A term which has come into popular use, designating more particularly that use of dynamite on a farm which enters into soil operations for the direct improvement of cultural conditions, as distinguished from the more established uses of the explosive in the removal of trees, stumps and bowlders, the removal of stumps and logs, excavating for foundations, digging wells and post holes, and in other similar kinds of work. This particular use has for its purpose the loosening of the soil as a means for the removal of difficulties in drainage, aëration, and moisture absorption resulting as a rule from hardpan or otherwise similarly compacted conditions near or within a few feet of the surface. Many soils have the tendency to become compacted just below the depth of plowing, and the dense and hardened layer formed there is as impervious to water as are the typical hardpans. To remove these unfavorable conditions in a quick and effective manner the land is subsoiled by means of dynamite if the cost of the operation does not outweigh prospective returns. The manner of procedure is largely determined by the character of the sub-

soil to be broken, its thickness, and its depth below the surface. Holes $1\frac{1}{2}$ inches in diameter are made with a soil auger or an iron bar at such intervals that the effect in the soil produced by one explosion meets that of the ones next to it. For this reason the holes are generally placed the same distance apart in both directions. When the holes are spaced 8 to 10 feet apart, they are made from $2\frac{1}{2}$ to 3 feet deep and half a stick or a whole stick of dynamite is used in each. Sometimes the holes are spaced only from 4 to 8 feet apart and made only about 2 feet deep. With this depth, a charge of $\frac{1}{4}$ of a stick of dynamite will generally have the desired effect. In thick hardpan the distance between holes ranges from 15 to 30 feet and the charge, consisting of 1 to $1\frac{1}{2}$ sticks, is placed about a foot above the bottom of the hardpan. The downward action of the dynamite explosion is quite marked, a charge placed $2\frac{1}{2}$ feet deep shattering even in heavy soils to a depth of about 4 feet. The best results with the holes 15 feet or more apart are secured by exploding a number of charges at the same time by means of electricity, but at the closer distances the explosion of each charge by itself with fuse and blasting caps serves the purpose. In preparing soil for tree planting the holes are made where the trees are to stand and the charges are most readily exploded individually. Before setting the trees, any cavity that may have formed is filled to prevent the possible gathering of water, the more rapid drying of the soil, or the sinking of the tree with the probable settling of the soil. Dynamite is also used in opening the underlying soil of swampy places to allow the water to pass into the lower layers. It is also used in the construction of drainage and other ditches. In all this work a slow-acting or low-strength dynamite, designated as 25, 30, or 40 per cent, carries the shattering effect to greater distances in the soil and gives better results than a quick-acting or high-strength dynamite.

DYNAMITE GUN. See AIR GUN.

DYNAMO-ELECTRIC MACHINERY. Machinery in which mechanical energy is converted into electrical energy, or vice versa, by means of magnetic induction. According to this definition, every dynamo-electric machine is capable of serving either as a generator or as a motor according to whether it is supplied with mechanical or electrical energy and whether it is therefore giving out electrical or mechanical energy respectively. In an electric generator mechanical energy is converted into electrical energy by means of continuous relative motion between electrical conductors and a magnetic field, or fields, such motion causing the conductors to cut the lines of force of the fields. In an electric motor electrical energy is transformed into mechanical energy by means of continuously supplying a system of electrical conductors with an electric current, which causes a magnetic force to act between the conductors carrying it and the magnetic field, or fields, thereby producing continuous relative motion between the conductors and the magnetic fields.

The preceding definitions are general and necessarily technical. To comprehend them fully a knowledge of the fundamental principles involved in the operation of dynamo-electric machines is necessary. They may, however, be in a measure elucidated by a descriptive defini-

tion as follows: All generators consist essentially of one or more electromagnets between the poles of which an armature, consisting of a soft iron core wound with coils of insulated copper wire, is made to revolve very rapidly by means of a steam engine, a water wheel, or other prime mover. The current produced in the generator may be transmitted by wires to a considerable distance and there be converted into mechanical energy again by being made to pass through another machine, similar and often identical in construction, and there cause the armature to revolve, and this revolution may be employed to do any kind of mechanical work. This second machine, working in reverse order from the first, is an electric motor. This description makes it clear, as definitions, that to understand dynamo-electric machine requires a knowledge of three great branches of electricity, and mechanics.

This special knowledge makes the subject of dynamo-electric machines a difficult one to discuss in universally familiar terms. At best, therefore, only an indication of the structural details and operating principles involved is possible under such conditions.

Fundamental Principles. To understand the fundamental principles involved in the operation of dynamo-electric machines, consider first two magnetic poles, *N* and *S*, of opposite polarity placed near to each other, as in Fig. 1. Between the poles *N* and *S* is a field of magnetic force

FIG. 1.

composed of so-called lines of magnetic force, which may be pictorially indicated by parallel lines, as is done in the illustration. If a conductor, e.g., a round copper bar *C*, is placed in the magnetic field, with its axis horizontal and perpendicular to the lines of force, and is raised and lowered along the path *CD* so as to cut the lines of force, an electromotive force is set up or induced in the conductor. The magnitude of the electromotive force produced in the conductor depends upon the rate at which the lines of force are cut. Owing to this electromotive force, one end of the conductor is raised to a higher electrical potential than the other, in consequence of which there is a tendency for electricity to flow along the conductor, and if its two ends are electrically joined by a conductor exterior to the magnetic field, a current will flow through this circuit. If the gap between the poles *N* and *S* were infinite in extent in the direction *CD*, and if the conductor *C* in its motion along this infinite path were supplied with some sort of sliding contacts, so that a closed circuit would be maintained, the device would possess all the essential features of a generator or of a motor. An equivalent condition is secured (1) if the magnet is bent so that the *N* and *S* poles face each other across a narrow gap; (2) if the conductor *C* is arranged so as to rotate in the gap between the *N* and *S* poles as a radius pivoted on the common axis of *N* and *S*; and (3) if sliding contacts are provided at the centre of rotation and at the extremity of the conductor outside of the polar forces; the device then be-

comes a homopolar generator or motor. The conductor *C* may be replaced by a rotating metal disk with similar contact devices.

The form of machine just described is noteworthy chiefly because of its simplicity and the fact that it was the first form to be invented. All commercial machines now in use operate in such a manner that the conductor moves alternately forward and backward through the field of force. To illustrate, if the conductor *C*

FIG. 2.

(Fig. 2) be attached to the circumference of a cylinder or other round body, which rotates about an axis \perp perpendicular to the paper, it will cut the lines of force by alternate downward and upward motions. An electromotive force in one direction will be generated in the conductor *C* as it is going up, and in the opposite direction as it is coming down. If the ends of *C* are brought to the shaft *A* and formed into rings around it, brushes bearing on these rings, if connected to an external circuit, will receive an alternating current, i.e., one which flows first in one direction, then in the opposite direction. Machines of this description are called *alternators*; the rotating part is called the armature; the pole *N* and *S*, with the remaining magnetic circuit, are called the field; and the rings around the shaft are called collector rings. If the current collected is to flow always in the same direction in the circuit which is external to the machine, some device must be provided to change automatically the connection between the armature circuit and the external circuit. Such a device is called a commutator. Its operation may be explained as follows: If in Fig. 2 the ends of the conductor *C* are brought down to the shaft *A* and extended across to the opposite side of the shaft, and then parallel to it so as to make the complete loop shown by Fig. 3, it will be obvious that the electromotive forces generated in the two sides of the loop will be opposite in absolute direction as indicated by the arrows, but in the same direction as regards the conductor itself.

If now the two ends *m* and *n* of the loop are attached to two half rings upon which brushes *b* and *b'*, composed of thin strips of metal or other conducting material, rest, and these brushes are placed at such points that they pass from one half ring to the other at the same moment that the conductor *C* ceases cutting lines of force in one direction and begins to cut them in the other direction, the current in the external circuit *c* will always be in one direction. Machines of this description are called *direct-current ma-*

FIG. 3.

chines. When the machine is operated as an alternator as first described, the direction and intensity of the current may be represented by the ordinates or vertical distances from the axis OX of the curved line $ABCD$ in Fig. 4, of

FIG. 4.

which the abscissæ or distances along the axis represent time. To illustrate, the distance AE represents the time of one complete revolution of the conductor. For half this time the current

FIG. 5.

is in one direction represented by the curve above the axis and has an intensity rising from nothing at A to a maximum at B and then falling to nothing at C . For the other half of this time the current is represented by the curve below the axis and has an intensity increasing from nothing at C to a maximum at D and then decreasing to nothing again at E . When the machine is operated as a direct-current machine, the current produced may be represented by the curve $ABCDE$ in Fig. 5, of which the ordinates and abscissæ have the same significance as in the curve previously explained. It will be noted that the curve being always above the axis shows the current to flow always in one direction, but to fluctuate in intensity. This excessive fluctuation is due to the fact that there is but one rotating coil, as shown by Fig. 3. Were another coil at right angles to the first to be added to the armature, the maximum electromotive forces in it would occur at the moments when there were no electromotive forces acting in the first coil. Likewise, if many coils are employed, the maximum electromotive forces of the several coils will occur at different instants, and if these coils are so connected that their electromotive forces are added to one another, the fluctuations will neutralize each other and the current obtained will be more uniform.

FIG. 6.

Thus far in this discussion the existence of a magnetic field has been assumed without inquiring in what manner it was provided. The manners in which such fields may be provided will now be described. In the earliest machines, and in many used for ignition purposes and the ringing of telephone signals, the field is provided by a permanent magnet which may be of the form shown by Fig. 6. In all machines of any considerable

size, however, the permanent magnet is replaced by an electromagnet. The method of producing such a magnet is indicated diagrammatically by

FIG. 7.

Fig. 7, in which the cast-iron or steel yoke A is wound with a coil of wire, aa . If a current flows through the winding in the direction indicated by the arrow, magnetic poles will be produced at N and S , and a magnetic field will exist between them. The parts of the magnet may differ much in form and arrangement, but a magnetic circuit ANS interlinked or wound with an electric circuit aa , is an essential feature. A direct current is required for exciting the field.

FIG. 8.

This may be obtained from some external source, or, in the case of a direct-current generator, from the machine itself. There are three ways in which this self-excitation may be accomplished. If current is taken from the positive brush and led directly through the magnet winding and back to the negative brush, as shown by Fig. 8, the magnet is in parallel or shunt with the external circuit, and the machine is called shunt wound. In a shunt-wound machine only part of the current generated passes through the magnet winding. If, however, all of the current coming from the armature passes through the field magnet and then goes to the external circuit, as shown by Fig. 9, the machine is called series wound. If both shunt and series windings are employed, the machine is defined

FIG. 9.

As shown by Fig. 9, the machine is called series wound. If both shunt and series windings are employed, the machine is defined

as compound wound. Compound windings are of two classes, defined as long shunt and short shunt. In the former the current used in the

Fig. 10.

shunt windings is also passed through the series winding along with the main current, as shown by Fig. 10. In the latter the current from the shunt coils passes directly back to the armature, avoiding the series turns, as shown by Fig. 11. The field magnets of alternators are excited by a current from a source exterior to the machine, usually from

an auxiliary direct-current dynamo, called the exciter. The relative arrangement of the field-magnet winding and the exterior circuit in separately excited generators is shown by Fig. 7. The machines shown in these various diagrams, and in fact all the machines so far mentioned, have had but two magnetic poles. It is evident, however, that there may be as many pairs of poles as is desired, so long as the armature connections are arranged to correspond. Machines having only one pair of poles are called *bipolar machines*; machines having two or more pairs of poles, are called *multipolar*. Most machines now built, except those of very small size and those driven at very high speed, are multipolar machines, a typical form being shown in Fig. 12. There are usually as many brushes bearing on the commutator as there are field poles, but this is not absolutely

Fig. 11.

Fig. 12.

usually composed of cast iron or steel. The pole pieces may be of the same material as the field, or they may be composed of soft iron laminae or sheets, placed edge on to the shaft of the machine. In small and medium-sized machines

the base and pillow blocks of the armature shaft are nearly always cast in one piece with the field. The body of the armature upon which the conductors are wound is always built up of iron laminae placed edge on to the shaft. The object of using laminae here and in the pole pieces is to prevent electric currents from flowing in the iron of the armature itself. Such currents would absorb power and needlessly heat the armature. The conductors themselves in both the field and the armature windings are copper wires or bars carefully insulated from the iron parts and from one another by cotton thread, or cloth, paper, cardboard, mica, etc. The commutator of direct-current machines is built up of copper segments separated by strips of mica. The brushes bear upon the commutator in the most modern machines take the form of blocks of carbon. In alternating-current machines there is no commutator, it being replaced by copper, brass, or iron rings.

Historical Development. In the preceding paragraphs the several parts of dynamo-electric machines and the functions which they exercise have been described, and the attempt has been made to elucidate briefly and nontechnically the principles at the basis of their operation. An account will now be given of their development, and afterward the several types of machine in commercial use will be described.

The principle of electromagnetic induction, upon which the operation of the dynamo-electric machine is based, was discovered by Michael Faraday in 1831. In his first experiments Faraday produced a current in a coil of wire by starting or stopping a current in a neighboring coil. He then generated currents in a coil by moving it before the poles of a magnet. His first electric motor was a homopolar machine. A disk of copper was so mounted that it could rotate between the poles of a permanent magnet transversely to the direction of the lines of force. When a current was applied at the axis of the disk and led off at the periphery, the disk rotated continuously. Faraday constructed a number of machines upon this principle, one of which consisted of a copper hollow cylinder closed at one end and hung over and inclosing a bar magnet. The cylinder rested upon a vertical pivot at the closed end and the open end dipped into a cup of mercury. When a current was caused to traverse the cylinder lengthwise, the cylinder rotated continuously about the magnet. Faraday's next machine employed a rotating rectangle of wire like that shown in Fig. 3 above, except that no magnet was used such as is shown in the drawing. When the axis of the rectangle was placed east and west and the rectangle was rotated, alternating currents could be drawn from slip rings attached to the coil, or, by employing a commutator, direct current could be obtained. It will be noted that the only magnetic field employed was that of the earth. The first machine to give a continuous current was constructed by Sir Charles Wheatstone, an Englishman, in 1841. The armature of his machine was wound with six coils, each of which was connected to the brushes only at the instant when it was at its greatest activity. The use of electromagnets instead of permanent magnets for the field was patented by Wheatstone and Cooke in 1845. A self-excited machine was constructed by Jacob Brett in 1848. The drum-wound armature in which the conductors are wound on the outside

of an iron cylinder or drum was introduced by Werner Siemens at about the middle of the last century. At about the same time or a little later a type of armature constructed in an entirely different fashion was introduced by Gramme. Instead of winding the wires on the outside of a cylinder placed between the magnet poles, he wound them upon an iron ring. The Gramme-ring type of armature was at one time extensively used, but it has almost entirely disappeared from use at the present time. Designs of multipolar machines began to appear about 1880, and it was at that time also that engineers began to study the principles entering into the design of dynamo-electric machines for commercial purposes. Since 1880 the greatest development has been in the direction of improving details of design and of mechanical construction.

Commercial Types. Turning now to the different types of dynamo-electric machines in use, it may be said in general that as they are now built in Europe and in America such machines differ in very few and in nonessential particulars. Only what may be called the standard types of dynamo-electric machines now in commercial use are described below.

Constant-current, direct-current machines were formerly much used for series arc lighting (see ELECTRIC LIGHTING). The essential feature of such a system is to maintain a constant current through the lamps, independent of the number of lamps in circuit, which of course necessitates a variation in pressure or voltage at the terminals of the dynamo. The required regulation of pressure in the old types of arc-lighting machines was accomplished by an automatic shifting of the brushes, causing some of the coils to act in opposition to other coils, thus counteracting each other and reducing the voltage, or vice versa. In modern practice, the direct-current series arc is extensively used in conjunction with constant-current mercury-arc rectifiers which convert alternating current from standard constant potential sources into a direct current of constant value. Alternating-current series lamps are supplied through constant-current transformers. See RECTIFIER; TRANSFORMER.

By far the greater number of direct-current machines are constant-potential machines and these are not separately excited, either shunt wound or compound wound. Generators of this type are used for supplying current for electric street railways, incandescent lighting, electrolytic work, and other purposes for which a direct current of comparatively low voltage is desired to be supplied at a constant potential irrespective of the load. In separately excited or shunt-wound machines the regulation of the current to constant potential is usually performed by means of a rheostat or variable resistance in series with the field winding. By increasing or decreasing this resistance, usually by hand, the field current and therefore the electromotive force are decreased or increased. In compound-wound machines the regulation is accomplished as follows: When there is no load upon the generator, the excitation of the magnets is produced entirely by the shunt winding, but as the load is increased the current flowing through the series coils aids that in the shunt coils, thus producing stronger fields and increasing the electromotive force at the generator terminals. The exact regulation of generators to

the proper terminal voltage is now largely accomplished by an automatic device which connects across the terminals of the control rheostat a low-resistance shunt at intervals whose frequency varies with the degree of regulation required. Small direct-current generators, whether operated at constant current or constant potential, are usually driven by belting from the engine or other prime motor, but large machines, in modern practice, are connected directly to the shaft of the prime motor. Typical direct-current constant-potential generators are shown on the adjoining pages.

The direct-current machine used as a motor will now be considered. If a dynamo-electric machine which has been connected for working as a generator be supplied with a current from an exterior source instead, it will run as a motor, the direction of the rotation depending upon the manner of the field excitation. A series machine, since both the armature and field currents are then reversed, will run in the opposite direction from that in which it was driven as a generator with the same electric polarity. A shunt-wound machine will rotate in the same direction when run as a motor as it did when driven as a generator, for, while the armature current is reversed, the field current remains unchanged in direction. A compound-wound machine will rotate in the same direction or in the opposite direction as a motor that it did as a generator, according as the shunt or the series winding is the more important; and while the field excitation as a generator was the sum of the series and the shunt windings, the field excitation as a motor is their difference. Another peculiarity of the dynamo-electric machine when operated as a motor which requires to be noted is that in such a machine operating as a generator there is only one electromotive force acting, but in the same machine operating as a motor there are two opposed electromotive forces acting. The reason for this is that the armature of a motor revolving in a field has an electromotive force induced in it exactly as in a generator. The direction of this induced electromotive force is, however, such as to oppose the current flowing through the armature under the influence of the external supply of electromotive force. Therefore this pressure, which is induced in the armature of a motor, is called counter electromotive force.

The current in the armature is due and proportional to the difference between the applied electromotive force and the counter electromotive force. The counter electromotive force is proportional to the product of the speed of the conductor and the field strength. It is evident that when the armature of a motor is at rest there is no counter electromotive force acting, and that the highest speed it may reach is that at which the counter electromotive force equals the applied electromotive force. In starting up a motor an external resistance has therefore to be provided to take the place of the counter electromotive force in order to resist an excessive inrush of current to the motor and prevent possible destructive action from it before the inertia of the armature has been overcome and rotation begun. This exterior resistance is commonly provided by a starting box, or rheostat, which is a device by which the current is gradually applied. Destructive currents may also arise during operation from various causes, and, to prevent damage from these, automatic attachments

are often provided, which open the circuit and stop the current. The turning effect or moment of an armature, technically known as its torque, is proportional to the product of the armature current and the strength of the magnetic field.

The effect of changes of load on the performance of a motor will be briefly considered. An increase in the mechanical load demands a torque greater than that being developed and tends to reduce the speed of the motor. The falling speed reduces the back electromotive force of the armature and so causes it to take an increased current sufficient to provide the required torque at steady speed. Conversely, if the load is reduced, an increase of speed occurs, and the current through the armature is reduced. If the field strength is only slightly affected by the changes in armature current, as in the shunt motor, the natural changes of speed with load are small, and the motor is adapted to service requiring approximately constant speed. In the series motor, however, the field strength varies greatly with the armature current, and an increased torque requirement involves a marked speed reduction. Conversely, the series motor increases greatly in speed with a fall of load and may rise to a dangerous speed if the load is entirely removed. The series motor finds its field where heavy torque at low speed and high speeds at light loads are desired, as in railway operation.

The regulation of the speed of a shunt motor rests upon the principle that at any load the speed must be such as to cause the armature to develop the proper counter electromotive force. If the field strength is reduced, the speed tends to rise. If the voltage applied to the armature is reduced while the field strength is kept constant, less counter electromotive force is required, and the speed falls. Speed-control systems for shunt motors are therefore of two general kinds, viz., those which adjust the field strength and those which vary the voltage applied to the armature. For very wide ranges of control these two systems are often combined. Very wide ranges of speed are apt to cause motors to spark badly at the commutator, and a special form of field structure is often employed to correct this tendency. Narrow poles with series windings are placed midway between the main shunt-wound poles and serve to produce in those armature coils whose connections are being reversed at any instant local electromotive forces which overcome the reluctance of the currents in these coils to reverse.

Probably the form of motor which is used in the greatest numbers is the *direct-current street-railway motor*. A series-wound motor operating on a constant-potential circuit is universally used for street-railway work. These machines have to be unusually sturdy to withstand the conditions of service which require them to endure the shocks and jolts due to rough track, as well as the dust, mud, slush, and rain of storms and dirty streets, and often the abuse of ignorant or careless motormen. Street-railway motors, one of which is illustrated by Fig. 13, are usually constructed with four poles, but use only two commutator brushes, placed in such a position as to be easily accessible. The field frame which carries the poles is made of such shape as to inclose all the working parts and thus protect them from dirt and moisture.

It is general practice to equip each trolley car

with at least two motors and to regulate the speed of the car in the following manner: First, the two motors and a resistance are connected in series. The resistance is then cut out step by step until the two motors are operating in series on 500 volts. This is called a running connection. To increase the speed further, the motors are placed in parallel with a resistance in series with both. This resistance is then cut out step by step until the motors are each operating on 500 volts. This again constitutes a running connection. A further change is sometimes effected by placing a small resistance in shunt with the fields when all the series resistance is out. This reduces the field flux and causes a higher armature speed to maintain the necessary counter electromotive force. A car governed in this way has four running connections. On heavy cars, such as are used in elevated-railway or interurban service, four motors are used on each car. In this case the motors are governed in two series-parallel combinations, as if there were two separate cars governed by one controller. In many of the recently installed interurban systems the trolley voltage is either 1200 or 2400. In such systems the unit of control is a pair of motors connected in series. The different connections are made by a motorman, who operates a handle on top of a controller. Each different combination is called a point, or notch. A pointer fixed to the controller handle indicates at what notch the car is running. A controller is almost invariably placed at each end of the car and is familiar to every one as an upright cylindrical device with a cranklike handle on its top. The interior of an ordinary street-car controller is shown in Fig. 14. The wires from the trolley, from the field, from the armature, and from the different terminals of the series and shunt resistance are brought up under the car to terminals on a connecting board in the bottom of the controller. On this connecting board there is also a switch, which enables an injured motor to be cut out without interfering with the operation of the other. From the connecting board conductors are run to terminals called fingers, or wipers. Mounted on an insulating cylinder,

FIG. 13. RAILWAY MOTOR (G. E. FORM).

which may be revolved by the controller handle, are insulated sectors, which at various angular positions of the cylinder make electrical connections between various wipers and give the proper connections for the various points or notches.

A smaller cylinder connected to a reversing lever is situated to the right of the main cylinder. This has contact sectors which are arranged so as to enable the motorman to reverse the direc-

FIG. 14. CONTROLLER.

tion of rotation of both motors or to cut them out entirely.

For power distribution in factories, both series and shunt motors are used. The series motor is employed where a powerful starting effort is required, as on cranes and hoists, but where close speed regulation is unimportant. The speed of the shunt motor may be controlled by controlling the applied electromotive force, as explained above, and the shunt motor is thus especially adapted for driving machines at constant speed or at speeds requiring definite adjustment. The characteristics of the compound-wound motor are intermediate between those of the shunt and series motors.

Converters, Dynamotors, Boosters, etc. Before passing to the subject of alternating machines proper, some types of machines possessing certain special properties which make them extremely useful devices under certain circumstances will be briefly considered. If the armature winding of any direct-current dynamo be tapped at two points which are opposite in phase, i.e., represented by a distance equal to that between two consecutive field poles, and these taps are led to two slip rings upon the shaft of the machine, alternating currents may be drawn therefrom. If the machine be run as a motor by supplying it with direct current delivered to the direct-current brushes, then alternating currents may be drawn from the slip rings. If, after the machine is brought up to full speed, alternating current of the same periodicity, or the same number of alternations per minute, as the machine will produce when run as a generator at this speed, be supplied to the slip rings, it will run as a synchronous motor, and direct current can be drawn from the regular direct-current brushes. To summarize, then: by simply tapping the armature winding of a direct current dynamo in the manner described,

a machine is produced which will act as an alternating-current generator as well; which will transform direct current into alternating, and which will also transform alternating current into direct current. According as the machine is used for the first, second, or third of these purposes it is called a double-current generator, an inverted converter, or a rotary converter. These machines are most commonly employed to transform alternating current into direct current and are commonly termed *rotary converters*. One of the principal uses of rotary converters is in electric-railway operation, where the distance of transmission is great. For long-distance transmission alternating current is desirable, since it may be raised easily to a higher potential, as will be explained below. The current for operating the car motors is usually, however, direct current, so that, when energy is transmitted in the form of alternating currents, rotary-converter substations are placed at intervals along the line to convert the alternating current to direct current for distribution to the trolley line. Rotary converters are usually operated on the three-phase alternating-current system as described below under *Alternating-Current Machines*. A *dynamotor* is a transforming device combining both motor and generator action in one magnetic field by employing two armatures or one armature having two separate windings. These machines enable one to take direct current from a system of supply at one voltage and deliver it at another voltage to a circuit in which it is to be utilized. They are used in electroplating works and for various minor purposes. *Motor generators* are transforming devices consisting of two machines, a motor and generator, mechanically connected. A *booster* is a machine inserted in series in a circuit to change its voltage and may be driven by an electric motor or otherwise. Boosters are used extensively in street-railway systems.

Alternating-Current Machines. Dynamo-electric machines for generating alternating current have been mentioned several times in the preceding pages. Before proceeding to discuss this type of dynamo it will be desirable to define the terms "single phase," "two phase," and "three phase," which will be frequently used in this discussion. All the alternators so far mentioned have been single-phase machines. If in Fig. 3 slip rings had been substituted for the commutator, the armature winding there shown would deliver a current which would reverse twice during each revolution of the armature. If another winding be added, the position of which on the armature is at right angles to the first, and this winding be also provided with slip rings, it will likewise deliver an alternating current which will be of the same periodicity as that delivered by the first. It is evident, however, that the current in the second winding will come to its maximum value one-quarter period later than in the case of the first winding. The currents in the two windings are said to differ in phase by a quarter of a period, and the machine is spoken of as a quarter-phase or two-phase machine. If the values of the currents are plotted as ordinates (verticals) in a diagram where the abscissæ (horizontal) represent time, the curves produced will be like those shown in Fig. 15, where the distance from *a* to *b* represents the time of one revolution, or two alternations, and the distance from *a* to *c* represents one-quarter of a revolution, or the time elapsing

between the instant when the current in the first winding is zero to the instant when the current in the second winding is zero. If about the circumference of the armature there were three wires spaced at equal distances, and these wires were connected at a common junction at one end of the armature and to three separate slip rings at the other end, the currents flowing in the three wires would reach their maximum at periods one-third of a revolution from each other, and the curve diagram would be as shown by Fig. 15. To apply the explanation given above to multipolar machines, the terms "complete revolution" and "circumference of the armature" should be understood to mean time taken by a conductor to pass by two poles and space upon the armature covered by two poles. Also, while the explanation considers only alternating machines which have stationary fields and rotating armatures, it is evident that the rotative mobility of the two may be reversed. In fact, in most large machines directly connected to the prime motor, the field is the rotating part. In this case the armature connections are merely fixed taps, and the exciting current is supplied to the field through slip rings. In the inductor alternator both the field winding and the armature are stationary, the only revolving part being the inductor—a laminated iron core with

FIG. 15.

polar projections which cause the magnetic lines of force to cut alternately into and out of the armature coils and so induce electromotive forces in them.

The so-called "turbogenerator" is a type of dynamo-electric machine that merits particular mention, as it is becoming more and more extensively used, especially for large alternating-current generators. The lower limit to the size of a generator for a given output is fixed by the maximum speed for which the prime mover can be designed—at least this is true if the generator is directly connected to the engine shaft, and for large units this is the only practical way. The speed of a reciprocating engine of high power must necessarily be slow, and in consequence the size of the generator soon becomes prohibitive, both on account of the difficulties of construction and the space which the finished machine occupies. However, these difficulties are overcome by employing a steam turbine (q.v.) as the prime mover. The characteristic feature of such a machine is that it must be run at exceedingly high speeds, and in consequence the connected generators must be designed to withstand the enormous strains resulting from this high rotative speed. This is accomplished by making the revolving part as small in diameter as feasible and using in its construction only the very strongest material; in case of alternating-current turbogenerators the revolving part is invariably the field, the core of which is usually made of nickel steel and the field winding of insulated copper strap held in place by bars of phosphor bronze.

Alternating-current motors may be classed as *synchronous* and as *nonsynchronous*. The rotary converter above described represents quite well the first class. Such motors are not in extensive use, on account of the fact that they must be

FIG. 16.

brought up to full speed before they can be thrown into circuit. They, of course, run at the same speed as, or keep in step with, the generator which is furnishing the current. Nonsynchronous motors are of two kinds, the induction motor and the recently developed alternating-current synchronous motor. In order to explain the principle of an interesting property of multiphase current must be described. Fig. 17 is shown, diagrammatically, a four-pole synchronous motor. If a current is sent through the two poles A and A', there will be established a magnetic field across from A to A' in the direction of the arrow No. 1. Similarly, if a current is sent around B and B', a magnetic field will be established across from B to B' in the direction of arrow No. 2. If both currents are sent at the same time and are of equal strength, the resultant field will be in the direction of arrow No. 3. Now, if the A current and the B current are alternating and differ in phase 90°, i.e., if the A current has its maximum value when the B current is zero, and vice versa, then starting with the A current at its maximum the magnetic field between the poles will at first be in the direction of arrow No. 1; then, as the B current increases and the A current decreases, the field will change in direction, until when the

FIG. 17.

A and B currents are equal it will be in the direction of arrow No. 3; as the A current continues to decrease to zero and the B current to increase to its maximum, the direction of the field will change into that of arrow No. 2, then as the A current takes a negative value and the B cur-

rent decreases from its maximum, the field will continue to change its direction, until, for a complete cycle of either the A or B current, the field will have taken all possible directions, about the point O ; in other words, the magnetic field will rotate with a period of revolution equal to the period of the current. If then an armature is mounted between the poles, and this armature is provided with a short-circuited coil, the field will induce current in it. These currents will in turn set up a second rotating field tending to oppose the rotating field due to the fixed coils AA' and BB' , and the pull between the two fields will cause the armature to revolve. Such a device is called an induction motor. In actual practice the field, or stator, of an induction motor is provided with a so-called distributed winding similar to that on the armature of a motor, so that there are no polar projections as shown in the figure, but the effect of this winding is equivalent to that of the simple winding discussed. It will be obvious that three-phase currents could be used as well as two-phase currents. Single-phase induction motors are also made in small sizes, but the principle according to which they operate is somewhat more intricate than that governing polyphase motors. Polyphase-induction motors are capable of being used for practically all the purposes to which shunt-wound direct-current motors are applied, and with proper controlling appliances may be used with more or less success in place of the series direct-current motors. They are simple in construction, have no moving contacts, and do not easily get out of order. They have been extensively employed in mills and factories, and in Europe they are used to propel electric-railway cars. Induction motors vary greatly in construction: the simple induction motor, however, is essentially a constant-speed machine. Like all other types of dynamo machine, the induction motor may be employed as a generator. To obtain this result, the armature must be driven faster than the revolving field, and polyphase currents must be supplied to the fixed element from some outside source to produce the requisite excitation.

The development of the alternating-current single-phase series motor is the result of the demand for an economical traction system for long-distance and heavy-railway work. The transmission of large amounts of electrical energy for any considerable distance is most economically accomplished by means of alternating currents. (See POWER, TRANSMISSION OF.) If direct-current motors are used, this energy has to be transformed by means of static transformers and rotary converters into direct current at a comparatively low pressure, and this low-pressure direct-current energy transmitted from the transforming station to the motor. The advantages resulting from the use of a suitable alternating-current motor are the elimination of the rotary converters and their attendant expenses, and an increased efficiency in the secondary transmission, as the final reduction of pressure to the value required at the motor can be accomplished by means of a small transformer carried on the car. Neither the synchronous nor induction motor is suitable for this purpose, for neither of them possesses the two essential features of a traction motor—large tractive force at starting and high effi-

ciency over a wide range of speed. The three-phase induction motor is employed to some extent both in Europe and America, mainly in mountainous regions with fairly long runs between stops. Where starts and stops are frequent, a series type of motor has marked advantages, due to its great torque at low speeds.

An ordinary direct-current series motor will run on an alternating circuit, since the direction of rotation is independent of the direction in which the current passes through the motor (a direct-current motor can be reversed only by changing the connection of the field and armature leads relative to each other), but at a great reduction in efficiency and power factor, due to certain peculiarities of alternating currents of too technical a nature to be considered here. However, these difficulties can be largely overcome by suitably designing the various parts of the machine. Two types of single-phase motors have thus been developed, the "series" motor and the "repulsion" motor. Both these types are alike in having an armature essentially similar in construction to that of the direct-current series motor. In the series type the field winding is similar to that of a direct-current machine, except that the iron used in the poles and yokes is laminated; the field and armature are connected in series. In the "repulsion" motor the field is similar to that of an induction motor; the brushes are short-circuited, and there is no electrical connection between field and armature. The armature acts like the secondary of a static transformer, and the brushes are set so as to maintain a constant repulsion between the primary (field) and the secondary (armature).

The controlling system for alternating-current motors contains no resistance, the necessary variations in pressure to secure a uniform acceleration at starting being accomplished by means of a device called a pole-changing switch which is essentially a static switch. Its coils movable with respect to each other. In an alternate type of control the reducing transformer has a secondary with taps by which the number of turns in the secondary can be altered to give any desired voltage. The efficiency of these controllers is much superior to that of the direct-current resistance system.

For long-distance power transmission alternating currents are used almost exclusively, as a large alternating current of low potential may be transformed into a small current of high potential by a transformer (q.v.), and by this means a great saving in the copper required in the transmission line may be accomplished. At the distant end of the line another transformation may be used to "step down" or reconvert the current to one of low potential. For long-distance transmission work three-phase currents are peculiarly adapted, as a three-phase current of a given potential may be transmitted with only three-fourths of the copper required for a single-phase. two-phase, or direct current working at the same pressure between wires. See POWER, TRANSMISSION OF.

DYNAMOMETER (from Gk. *dynamis*, *dynamis*, power + *μέτρον*, *metron*, measure). A device for measuring the force exerted in overcoming resistance and producing motion. The foot pound, as a unit of work, has for its factors the force acting and the distance through which it acts. The horse power, besides these factors, has a third—the time during which the force is exerted. Hence, in getting the data from which the work of a machine is to be calculated, we are to observe the force, the distance, and the time required to accomplish a certain result. Strictly speaking, the dynamometer indicates the first of these items, but it may be so arranged as to show both the others. Dynamometers are designed to indicate the force of *traction*, of *thrust*, or of *rotation*. A traction dynamometer consisting of some sort of spring balance may be interposed, e.g., between a team of horses and a reaper or a plow, to measure the force exerted by the horses in drawing the machine or on a larger scale may be used to measure the force exerted by a locomotive at the drawbar. A dynamometer for thrust can be connected with the screw shaft of a steamship to measure the force with which the screw is driving the vessel through the water. Rotary dynamometers measure the force of a shaft either by showing what force is required to hold the shaft in check, by absorbing the *energy*, or by ascertaining the force the shaft transmits to other machinery. In testing the Melville-McAlpine turbine reduction gear use was made of a 6000-horse-power hydraulic absorption dynamometer, where by means of vanes the water was heated to boiling temperature by friction. The Prony brake is the most commonly used dynamometer of this form and is found described, with directions for using it, in Kent's *Mechanical Engineer's Pocket-Book* (8th ed., New York, 1913). Consult also Carpenter's *Experimental Engineering* (7th ed., ib., 1912), and particularly the *Transactions of the American Society of Mechanical Engineers*, vols. vii-xv inclusive, under the index heading Dynamometers.

DYNAMOTOR. See DYNAMO-ELECTRIC MACHINERY, *Converters, Dynamotors, Boosters, etc.*

DYNE, *dīn* (abbreviated from *dynam*, from Gk. *dynamis*, *dynamis*, power). The unit of force of the C. G. S. system; i.e., it is such a force that under its action a body of mass 1 gram is given an acceleration unity. Bodies of all masses fall towards the earth with the same acceleration at any one place on the earth's surface, provided they are allowed to fall perfectly freely. (See GRAVITATION.) This acceleration for all places is about 980 on the C. G. S. system; therefore the *weight* of a body whose mass is *m* grams—i.e., the force of the earth acting on it, being the product of *m* and this acceleration of a falling body—is 980 *m* dynes approximately. The weight of 1 milligram is, then, 0.980 dynes, or nearly 1 dyne. Since a dyne is so small, a more common unit of force is a "megadyne," or 1,000,000 dynes, i.e., 10^6 dynes. See MECHANICAL UNITS: FORCE.

DYRENFORTH, ROBERT SAINT GEORGE

(1844-1910). An American soldier and lawyer, born in Chicago. He served at Breslau in 1861, served in the United States army in 1861-66, became major of volunteer cavalry, assistant inspector general and signal officer in the Department of the Missouri, and was several times brevetted. In 1866 he was correspondent of the *Chicago Post and Times* during the war between Austria and Prussia. He studied mechanical engineering at Heidelberg in 1866-69, entered the U. S. Patent Office in 1871, was examiner in chief during the administration of President Hayes, and assistant commissioner during that of President Arthur. He resigned in 1885 and practiced as a patent and corporation lawyer. In 1891 he carried on in Texas a series of experiments for the government, to condense water vapor into rain by violent explosions; he was, in consequence, popularly known as the "Rain Maker."

DYRRHACHIUM, *dīr-rā'ki-ūm*. See DURAZZO.

DYSCHROMATOPSIA, *dīs-krō'mā-tōp'si-ā*. Difficulty in distinguishing colors, or partial color blindness (q.v.).

DYSENTERY (Lat. *dysenteria*, Gk. *δυσεντερία*, *dysenteria*, dysentery, from *δυσ-*, *dys-*, bad + *έντερον*, *enteron*, intestine). A form of disease of the large, rarely also in the small, intestine, attended by frequent and scanty discharges from the bowels, and differing from diarrhoea (q.v.) chiefly in being attended by marked fever and pain, as also by the presence of blood and mucus in the discharges. Two forms of dysentery are recognized by medical authorities—sporadic and epidemic. In *acute catarrhal colitis* an increase in mucus occurs, which is thrown off with epithelial cells, serum, and blood, ulceration occurring, with swelling of the glands and formation of connective tissue. This is the ordinary form of dysentery, which is relieved by saline purgatives, astringent injections, opium, salol, and enemata of starch or hot water. *Acute infectious colitis*, or "tropical dysentery," is either caused by the presence of the *Amœba coli* ("amœbic colitis") or by the presence of *Bacillus dysenteriae*, as shown by Shiga in 1897 and Flexner in 1899. Amœbic dysentery is considered a distinct disease by modern physicians. Its true nature was discovered by Lösch in 1875 and described by Kartulis in 1886. In tropical dysentery necrotic and suppurative processes may be set up in the liver and in the right lung. The symptoms are largely the same as in catarrhal colitis, except that they are more severe; the mortality also is high. Tropical dysentery is rarely seen in immigrants coming to the United States. It is endemic in southern Europe. There is a chronic catarrhal colitis. There is also a form of dysentery, known as "croupous colitis," in which there occurs formation of a false membrane over the mucous lining of the intestine. To the variety of dysentery in which inflammatory changes are the most marked in the lymph nodes, the name *nodular* or *follicular* dysentery is given. If necrosis of the mucous membrane be extensive, the colitis is termed *necrotic*. All cases of dysentery which do not improve under milk or peptonoid diet and injections of starch and hot water should be speedily put into a physician's hands. By the use of a specific serum Shiga reduced the mortality about one-third in bacillary dysentery. In amœbic dysentery ipecac in large doses has

long been considered a specific. Consult L. Rogers, *Dysenteries: Their Differentiation and Treatment* (New York, 1913).

DYSLYSIN (from Gk. *δυσ-*, *dys-*, bad + *λυσις*, *lysis*, soluble, from *λυειν*, *lyein*, to solve). $C_{21}H_{29}O_8$. An organic substance obtained by boiling cholic acid with hydrochloric acid for some time. It is a neutral resinous body, insoluble in water, alcohol, and the alkalis, but moderately soluble in ether. Small quantities of it are sometimes found in feces.

DYSMENORRHEA, *dīs-mēn'ōr-rē'ā*. See MENSTRUATION.

DYSPEPSIA (Lat. *dyspepsia*, Gk. *δυσπεψία*, *dyspepsia*, from *δυσ-*, *dys-*, bad + *πεπτός*, *peptos*, cooked, from *πέπτειν*, *peptein*, to cook). Disordered function of the stomach, resulting in impaired digestion. The symptoms are: feeling of pressure or weight after a meal, burning (*pyrosis*), accumulation of gas, headache, coated tongue, drowsiness, and general weakness and discomfort. There may be a disordered condition of the mucous membrane of the stomach (*gastritis*), with pain and vomiting in addition to the symptoms noted; there may be a deficiency in the hydrochloric and lactic acids in the gastric juice; there may be excessive production of these acids; there may be a rapid fermentation of the food, with the production of gas and toxins, causing great pain in the stomach, severe headache, palpitation of the heart, and frequent raising of gas, this condition being termed flatulent dyspepsia. There may be a general nervous condition, with waste of nerve energy, the stomach being the first organ to fail in its functions; this condition being termed nervous dyspepsia. Gout, or lithemia, may be a cause of dyspepsia. In many cases constipation is also a symptom, and the use of cathartics has made the dyspepsia worse. Treatment must be directed to the cause, and in all cases diet must be regulated and daily out-of-door exercise practiced. Indigestible or irritating food should be avoided, such as smoked or salted meat, smoked or salted fish, hot breads, all fried articles of food, generally potatoes and roots, sweets, pastry, and oatmeal. Tea and coffee and all alcoholic liquors should be avoided, in general. Food should be thoroughly masticated and eaten slowly. In some cases the stomach should be washed out every day or two. Bitter tonics, such as strychnine, are helpful, also creosote, carbolic acid, kola, ginger, and various digestants, such as pepsin and papoid, in certain cases. Management is better than medicinal treatment in many cases. Consult Bigg, *Indigestion, Constipation, and Liver Disease* (London, 1913). See INDIGESTION.

DYSPHONIA (Neo-Lat., from Gk. *δυσφωνία*, harshness of sound, from *δυσ-*, *dys-*, bad + *φωνή*, *phōnē*, voice, from *φάναί*, *phanai*, to speak). Difficult speaking. It is attended with inflammation, huskiness, cough, expectoration, and sometimes ulceration. Rest of the vocal organs, muscular exercise, tonics, and change of air and scene, are helpful towards recovery. *Dysphonia clericorum*, or "clergyman's sore throat," is a glandular pharyngitis and laryngitis arising from the forcible and improper use of the voice. *Dysphonia puberum* is the term given to the changing voice at puberty, when it becomes harsh and inharmonious, and "breaks" when used. *Dysphonia spastica*, or "speaker's cramp," is a spasm of the muscles of phonation or respiration. In this variety of dysphonia there are

sudden changes to a high pitch, the voice becomes jerky, or aphonia occurs.

DYSPNOEA, *dīp-nē'ā* (Lat., from Gk. *δύσπνοια*, *dyspnoia*, from *δυσ-*, *dys-*, bad + *πνοή*, *pnōiē*, breathing). Difficult breathing; in popular speech "shortness of breath." *Dyspnoea* may be due either to lack of oxygen, to excess of carbon dioxide, or to the presence in the blood of certain products of muscular activity (*dyspnoea of exercise*). The condition may be either inspiratory or expiratory, or both, and the chief causes are obstruction of the nose, throat, larynx, trachea, and bronchi; diseases of the lungs or pleura; or pressure upon the diaphragm by gas, fluid, or tumors in the abdomen. It is also a symptom of anæmia, paralysis of the muscles of respiration, or pain in or about the chest. Diseases of the heart and kidneys are often attended with *dyspnoea*.

DYSPROSIUM. A chemical element contained in small quantities in ytterbite and obtained from this, in the form of the oxide (*dysprosia*), by Lecoq de Boisbaudran in 1886. Efficient methods of isolating *dysprosium* from its concomitant elements were discovered by Urbain in 1900, 1904, and 1906. *Dysprosium* (symbol, Dy; atomic weight, 162.5) forms a white oxide of the formula Dy_2O_3 ; a chloride of the formula $DyCl_3 + 6H_2O$; a nitrate (similar to bismuth nitrate) of the formula $Dy(NO_3)_3 + 5H_2O$; a sulphate of the formula $Dy_2(SO_4)_3 + 8H_2O$; and several other salts. The salts have a slight greenish-yellow tint. *Dysprosium* is remarkable as the most paramagnetic element known, its oxide being magnetic; it is more magnetic than the oxide of iron.

DYSTILOLOGY (from Gk. *δυσ-*, *dys-*, bad + *τέλος*, *telos*, end + *-λογία*, *-logia*, account, from *λέγειν*, *legein*, to say). The doctrine of purposelessness, or of the absence of final causes in nature. The term is sometimes used in the sense of frustration of purpose, as when cross pollination in plants is prevented because an insect punctures a nectary instead of entering the floral opening. See TELEOLOGY.

DYSURIA (Lat., from Gk. *δυσουρία*, *dysouria*, from *δυσ-*, *dys-*, bad + *ούρον*, *ouron*, urine). A difficulty of passing urine, which may depend on a variety of causes. See BLADDER; STRICTURE.

DYTISCIDÆ, *dī-tis'ī-dē*. See DIVING BEETLE.

DYVEKE, *dū've-kā* (1491-1517). The mistress of Christian II of Denmark. She was born in Amsterdam, the daughter of Sigbrit Willums, an innkeeper, in whose inn at Bergen Christian first met her. Dyveke followed him to Denmark in 1507 and until her death continued her relations with him. She was hated by the nobles and, it is supposed, met her death by poison administered to her in cherries by one of them. Christian cruelly avenged her death and retained her mother as his chief counselor till his fall. Dyveke has been made the subject of many tragedies, novels, and poems. Consult Hauch, *Ilse og Zübern* (Copenhagen, 1848), and Reikhsch, *Dyveke*, a tragedy (Berlin, 1843).

DZEREN, *džē'rēn*. The Mongolian name for a large Central Asian "goitred" antelope (*Gazella gutturosa*), having extremely pale horns and a protruding crop.

DZIATZKO, *dschäts-kō*, KARL FRANZ OTTO (1842-1903). A German librarian and scholar, born in Neu-Ladt, Silesia. He studied at the universities of Breslau and Bonn; in 1871 he be-

came librarian of the University of Freiburg, in 1872 librarian at Breslau, and in 1886 librarian and professor of library science at Göttingen. Among his publications are a text edition of the comedies of Terence (1884), *Instruktion für die Ordnung der Titel im alpinen Museum* (Breslau (1886), used, with comparison of other works, as the basis of K. A. Linderfelt's *Eclectic Card Catalog Rules* (Boston, 1890), and *Untersuchungen über ausgewählte Kapitel des antiken Buchwesens* (1900).

DZIERZON, dzēr'tsōn, JOHANN (1811-1906). A German apiculturist. He was born at Lobkowitz, Upper Silesia, studied theology at Breslau, and was pastor at Karlsmarkt from

1835 to 1869. Afterward he devoted himself entirely to apiculture, a subject to which he had for many years given considerable attention. In order to facilitate his investigations Dzierzon constructed a hive with detachable cells and thus made the discovery that the eggs for the propagation of the drones required no fertilization, but could be generated by the queens or even by the working bees. (See **PARTHENOGENESIS**.) His publications include *Theorie und Praxis des neuen Bienenfreundes* (1848) and *Rationelle Bienenzucht* (2d ed., 1878).

DZIGGETAI, dzīg'ge-tā or -tāi, or DJIGGETAI. Mongol names of one form of the Asiatic wild ass. See **ASS**.

DZUNGARIA, dzōōŋ-gā'rē-ā. See **SUNGARIA**.

E

E The fifth letter and second vowel in the Roman and most other alphabets. Its form is derived from the Phœnician sign p through the Greek and Roman scripts. The Semitic name for this character, *he*, is not a word with recognized signification, as is the case with most of the other letters. See ALPHABET; LETTERS.

Phonetic Character. The Greeks had two characters to represent the short and the long sound of our *e* in *let* and *they*. The short one, *ε*, was called *epsilon*; the long one, *η*, was designated as *eta*. In Latin also there were both a short and a long *e*, just as there were in primitive Indo-Germanic. In Sanskrit the sound of *e* was long, but it was shortened under certain circumstances in Pāli and in the vernaculars. Historically the Indo-Germanic short *ē* becomes *ā* in Sanskrit, *ē* in Greek and Latin, as in Idg. **bhērō*, 'I bear,' Skt. *bhārāmi*, Gk. *φέρω*, Lat. *fero*. The original long *ē* becomes Skt. *ā*, Gk. *η*, Lat. *ē*; thus, Idg. **plē*, 'fill,' Skt. *prā-ta*, 'full,' Gk. *πλήρης*, Lat. *plēnus*. Both long and short Indo-Germanic *e* appear under certain conditions as long and short *o* respectively. Thus, from Gk. *τρέπω*, 'I turn,' we have the noun *τρόπος*, 'turn'; similarly the long *ē* (*η*) in Gk. *πατήρ*, 'father,' appears as *ō* (*ω*) in *προπάτωρ*, 'forefather.' This phenomenon is called vowel gradation. In English, the single character *e* is used to represent a variety of sounds—*get*, *he*, *her*, *there*, and the like—and its employment to indicate that the preceding vowel is long, as in *ston(e)*, from AS. *stān*, is a device inherited from an earlier period of misspelling in the language. The frequency of *e* in English is largely due historically to its being the indeterminate or indefinite vowel into which the final endings *a*, *o*, *u* of the Anglo-Saxon period were weakened. The case in German is somewhat similar. In words borrowed from the Romance languages mute *e* usually takes the place of Greek or Latin final syllables, e.g., *muse*, Lat. *musa*; *bile*, Lat. *bilis*; *cone*, Lat. *conus*.

As a Symbol. *E* in music is the third tone in the natural scale of C; in the treble clef it is written on the first line or fourth space, and in the third space or the first added line below in the bass clef. As an abbreviation, *E.* stands for *East*.

EA, ENKI, or AE. A Babylonian deity of Sumerian origin. With Anu (q.v.) and Ellil-Bel he forms the highest triad in the Pantheon. He is associated with the ocean, and the earliest

seat of his worship seems to have been Eridu (modern Abu Shahrain) at a time when this city was on the Persian Gulf. Of all the gods he has the highest reputation for wisdom. He is a creator-god, forming man; and a friend of man (see ADAPA; DELUGE). This has led some scholars to identify him with Oannes (q.v.); Damascius gives his name as *ʿAos*, *Aos*, and some texts read *Ae*, which may have been the pronunciation. His consort was Dambina. Consult: Zimmern, *Die Keilinschriften und das Alte Testament: Religion und Sprache* (Berlin, 1902); Jastrow, *Die Religion Babyloniens und Assyriens* (Giessen, 1902-12); G. F. Moore, *History of Religions* (New York, 1914).

EA-BANI, ʾā-bā'nē. See ENGIDU.

EACHARD, ʼech'erd, JOHN (1636-97). An English clergyman and writer. He was educated at Cambridge, where he became master of Catharine Hall (1675), and for two terms was vice chancellor of the university. He published a number of satirical attacks upon the clergy, among them *The Ground and Occasions of the Contempt of the Clergy Inquired into, in a Letter to R. L.* (1670). In a similar vein of satire he attacked the philosophy of Thomas Hobbes in *Mr. Hobbes's State of Nature Considered* (1672).

EADIE, ʼē'di, JOHN (1810-76). A Scottish United Presbyterian theologian, born at Alva, Stirlingshire, and educated at the University of Glasgow and in the Divinity Hall of the Secession church (later United Presbyterian). He was licensed in 1835 and preached in Glasgow from 1835 till his death, June 3, 1876. From 1843 he was a synodical professor of biblical literature in the United Secession Divinity Hall in Glasgow, and his fame rests upon his writings in this department. Many had a very wide sale and are still in use, as his condensed edition of *Cruden's Concordance* (1839); *Biblical Cyclopædia* (1848; new ed., revised, 1902); *An Analytical Concordance to the Holy Scriptures* (1856); *Ecclesiastical Concordance* (1861). He prepared commentaries on the Greek text of Ephesians (1854), Colossians (1856), Philipians (1857), Galatians (1869), 1 Thessalonians (1877). He was a member of the New Testament Company of the Bible Revision Committee and in that connection published his important and well-known work, *The English Bible: An External History of Various English Translations of Scripture, with Remarks on the Need of Revising the English New Testament* (1876). He collected a remarkable library, which is now kept intact as the Eadie

Library in the United Presbyterian College in Glasgow. For his life, consult Brown (London, 1878).

EADMER (ĕd'mēr) OF CANTERBURY (?-1124). An English monk and chronicler of the early twelfth century. He belonged to the Benedictine monastery at Canterbury and was a devoted friend of Anselm, Archbishop of Canterbury, from 1093 to 1109. In 1120, at the request of King Alexander I, he went to Scotland and was chosen Bishop of St. Andrews. The question of lay investiture of ecclesiastical benefices was then a burning one, and there were controversies as to jurisdiction between St. Andrews, Canterbury, and York. The outcome was that Eadmer returned to Canterbury, consecrated. He became precentor at Canterbury and died, it is supposed, in January, 1124. His most valuable works are the *Historia Novorum*, or history of his own times, and his life of Anselm. They are both in the same volume of the "Rolls Series" (London, 1884), ed. by Martin Rule. His verses on St. Dunstan, St. Wilfred, St. Odo, St. Bregwin, and St. Oswald are published in Wharton, *Anglia Sancta*. His *Tractatus de Conceptione Sanctæ Mariæ* is republished (St. Louis, 1904). Consult Grub, *Ecclesiastical History of Scotland* (Edinburgh, 1861).

EADMUND, ĕd'mūnd. See EDMUND.

EADS, ĕdz, JAMES BUCHANAN (1820-87). An eminent American engineer and inventor. He was born in Lawrenceburg, Ind., but removed to St. Louis in 1833, became a clerk first in a dry-goods house and then on a Mississippi steamboat in 1839, and, having studied engineering by himself, set out to solve some of the problems of navigation on that river. By the outbreak of the Civil War he had achieved fame and a fortune and was accounted such an authority on everything pertaining to the Mississippi and its navigation that, soon after the fall of Fort Sumter, he was called to Washington to consult with President Lincoln and his cabinet as to the practicability of maintaining a fleet of light ironclads on the Western rivers. Later in the year 1861 he obtained the government contract for the construction of such a fleet and achieved the remarkable feat of placing in the water, fully equipped, seven ironclad river gunboats, largely of his own designing, in the short space of 100 days. It was with these gunboats, a month before the struggle between the *Merrimac* and the *Monitor*, that the capture of Fort Henry was effected. From 1867 until 1874 Eads was engaged in the construction of the steel arch bridge across the Mississippi at St. Louis, which ranked for many years as one of the finest bridges in the world. After the completion of this work he began studying the problem of deepening the channel at the mouth of the Mississippi and finally persuaded the government to allow him to undertake the enterprise at his own risk. His plan, which provided for the construction of jetties, was carried out successfully and was the crowning achievement of his career. The latter years of his life were spent in extensive engineering operations both in America and Europe, and the planning of a ship railway across the Isthmus of Tehuantepec. In 1884 he received the award of the Albert medal conferred by the British Society for the Encouragement of Arts, Manufactures, and Commerce, he being the first American to receive the award. Consult How,

James B. Eads (Boston, 1900), one of the "Riverside Biographies."

EADWINE; EADWIG. See EDWIN, EDWY.

EAGAN, ĕ'gan, CHARLES PATRICK (1841-). An American soldier, born in Ireland and brought up in San Francisco. He entered the Federal army from civil life in 1862, with rank of first lieutenant, and in 1866 he was appointed to the United States army, with rank of second lieutenant, and by 1900, when he retired, had risen to the grade of brigadier general and commissary general. During the Spanish-American War he issued among rations designed for forces in Cuba canned meats said to be unfit for food. In 1899 he was court-martialed for violent and abusive treatment of the War Investigation Committee. General Miles, commander in chief of the army, and was sentenced to a suspension of six years from duty and military honors. Later he was retired at his own request.

EAGLE (OF. *egle*, *aigle*, Fr. *aigle*, It. *aquila*, from Lat. *aquila*, eagle, from *aquilus*, dark brown; connected with Gk. ἀχλὺς, *achlys*, mist, darkness, Lith. *aklas*, blind). Any member of a group of birds of prey, variously defined, but typified by the genus *Aquila*, which contains the largest and most powerful of the Falconidæ. The subfamily Aquilinæ includes several genera and over 40 species. From the most ancient times the eagle has been universally regarded as the emblem of might and courage, as the lion, it has been fancifully invested with other attributes of greatness such as men thought to harmonize with these. Its extraordinary powers of vision, the vast height to which it soars in the sky, the wild grandeur of the scenery amid which it loves to make its abode, and perhaps also its longevity, have concurred to recommend it to poetic regard. It was associated with Jupiter in the Roman mythology, and its figure on the standards of certain Roman legions has descended to the national ensigns of the United States, Germany, Russia, etc.

True eagles have the beak not curved from the very base, like the true falcons, nor notched on the edge: neither are their wings so long in proportion to their size; their legs are very robust; their claws curved, sharp, and strong. In the most restricted use of the generic term *Aquila*, the true eagles (of which the golden eagle may be taken as a type) have a rather short bill, curved from the cere, with the edge of the upper mandible slightly sinuate, the tarsi short and feathered down to the toes. This last character distinguishes them at once from their nearest allies—the sea eagles of the genus *Haliaeetus*. Nine species of true eagles are well distinguished, although in this, as in allied genera, much confusion has arisen from the diversity of plumage at different ages. Only one of them occurs in North America. This is the golden eagle (*Aquila chrysaëtus*), of which the "ring-tailed" eagle is the young. It is 30 to 35 inches in length, and 6½ to 7 feet in spread of wing; the female is rather larger than the male. The color is dark brown, in some parts almost black; the head and back of the neck in mature birds are covered with pointed feathers of a golden-red color; young birds have a considerable part of the tail white; the bright-yellow cere and feet give it its name. The golden eagle is the largest of the European eagles and is found throughout Europe, Asia (north of the Himalayas), and most of North America. It preys on mountain-

ous districts, and usually only one pair exists within a relatively extensive area. These eagles are rare east of the Mississippi, but are occasionally seen, especially in winter. They build a coarse nest of large sticks on cliffs or rocky ledges in the mountains and lay two or three eggs, dull white, blotched, and speckled with brown. A great quantity of food is required to support a pair of these birds and their two or three young ones; and not only hares, game of every kind, and lambs are carried to the aerie, but larger animals are sometimes attacked.

The imperial eagle (*Aquila heliaca*) is usually regarded as that from which the Greeks and Romans adopted their symbolism and ranges from the eastern Mediterranean to China. It is somewhat smaller and darker than the golden eagle and seems to be less noble in its feeding habits and behavior; indeed, an impartial judgment must concede that the eagles do not nearly so well deserve the admirable qualities attributed to them by poetry and romance as do many of the lesser falcons—they are, in truth, not far removed from vultures in both structure and disposition. Much smaller, not exceeding 25 inches in length, are the spotted eagles (*Aquila maculata* and *Aquila clanga*) of central and southern Europe; while other less-prominent species are the tawny eagle (*Aquila rapax*) of Africa, the Indian tawny eagle (*Aquila vindhiana*), and the vulturine eagle (*Aquila vireauai*) of South Africa, which is marked by a white rump and must be distinguished from the eagle vulture (q.v.). See also HAWK EAGLE.

Sea Eagles. Next in importance come the sea eagles or ernes of the genus *Haliaeetus*, which haunt coasts and large river courses and feed mainly upon fish in all parts of the world. Here belongs the American white-headed or "bald" eagle, the national emblem of the United States (*Haliaeetus leucocephalus*)—an unfortunate choice when its predatory methods are considered. This eagle originally was numerous all over North America and still survives near the coast, around the Great Lakes, and along the larger rivers in considerable numbers, wherever it is not too ruthlessly persecuted. It is nearly as big as the golden eagle, but is not feathered to the toes, and its head, neck, and tail, after the third year, are perfectly white. It does not migrate, except from the most northerly, ice-bound portions of its range, and is indeed a home-keeper, a single pair sometimes occupying the same great nest of sticks, repaired each season, for many years in succession, followed perhaps by their descendants, for nests are known (one is near Cleveland, Ohio) which have not been vacant for nearly a century. Two is the usual number of eggs. This eagle feeds upon fish mainly. For the most part this is picked, dead or dying, from the surface or shore; bald eagles have always abounded in the neighborhood of Niagara Falls, because of the constant supply of fish found there, killed by going over the falls or being caught in the whirlpools below. They also regularly attack fish hawks and compel them to drop what they have caught. When fish are not obtainable, they eat carrion or kill small birds and mammals, as do the buzzard hawks, now and then capturing poultry.

The sea eagles of the Old World are larger than the bald eagle. The most familiar is the white-tailed erne (*Haliaeetus albicilla*), now nearly exterminated from Great Britain, except

in the far north of Scotland, but a familiar sight on the coasts of the Hebrides and thence eastward throughout Europe and most of Asia. In Siberia and Kamchatka still greater species are found, Steller's sea eagle, which ranges from China and Japan to the Aleutian Islands, attaining a length of 41 inches—the largest of its tribe. Africa has several species.

Crested and Other Eagles. Members of several allied genera are usually called eagles. A remarkable one is the "bataleur" (*Helotarsus caudatus*), of Africa, whose plumage is most strikingly variegated with maroon, black, and gray, and whose head is covered with large up-standing feathers; its food is mainly snakes and lizards. The buzzard and harrier eagles of the genera *Buteo* and *Circus*, whose several species are African and South Asiatic, are also fond of a reptilian diet; while the large handsome birds of an Oriental genus (*Spilornis*) are usually called by natives "serpent eagles" (q.v.); among the most conspicuous of these is the Philippine one (*Spilornis holospilus*), the whole plumage being brown, spotted with white. Several forms of handsome crested eagles are African and East Indian, and much that is interesting might be related of them and of the hawk eagles, did space permit. Australia possesses a single and peculiar species in the carrion-feeding wedge-tailed eagle (*Uroaetus audax*); and in the fierce tropical harpies (genus *Thrasaetus*) South America has representatives of this family almost equaling in size and surpassing in courage and power those of all the rest of the world. See HAWK EAGLE.

The literature relating to eagles is little separated from that of birds generally, as outlined under BIRD. For the limited use made of eagles in falconry, where they were counted "ignoble," see FALCONRY. See PLATE OF EAGLES AND HAWKS.

EAGLE. A military standard, used by various nations in ancient times. The Persians, in the time of Cyrus the Younger, bore an eagle on a spear as a standard. The Romans, for some time used the eagle, the wolf, the boar, the horse, and the minotaur for standards, but afterward abandoned the last four and confined themselves to the eagle. The Roman eagle, sometimes of gold, but more frequently of silver, was about as large as a pigeon with extended wings and was borne on the top of a spear or pole, with a crossbar or a metal plate or a shield to support it. Often the eagles were represented as holding thunderbolts in their talons; they usually bore the name of the legion to which they severally belonged. The lower end of the pole was pointed, so that the standard could be set in the ground.

EAGLE. A support of entry on the Yukon River, in Alaska, near the Canadian boundary (Map: Alaska, L 3). It is a trade centre for Fortymile and other mining camps. Fort Egbert, a garrisoned post, adjoins the town. Pop., 1910, 178.

• **EAGLE, BLACK, ORDER OF THE.** An order of chivalry in Prussia. It was founded by the Elector of Brandenburg, Jan. 18, 1701—the day of his coronation as King of Prussia. The number of knights, in addition to the royal family, was originally 30, but it is now unlimited. The order is conferred for distinguished merit in the military or civil service of the state and carries with it a patent of nobility. The insignia consist of a Maltese cross of blue enamel and a black eagle displayed between the

EAGLES AND HAWKS

1. BALD EAGLE (*Haliaeetus leucocephalus*).
2. DUCK HAWK or PEREGRINE FALCON (*Falco peregrinus anatum*).
3. HARPY EAGLE (*Thrasaetus harpyia*).
4. SWALLOW-TAILED KITE (*Elanoides forficatus*).

5. OSPREY or FISH HAWK (*Pandion haliaetus*).
6. NORTHERN ROUGH-LEG (*Archibuteo lagopus sancti-johannis*).
7. MARSH HARRIER (*Circus hudsonius*).
8. SPARROW HAWK (*Falco sparverius*).

arms of the cross. On a circular plaque in the centre is the royal cipher F.R., with a laurel branch below and the words *Sum cuique* (To each his own). The cross is suspended by a broad ribbon of orange color hung across the left shoulder, and with it is worn an embroidered silver star fastened on the left breast. The centre of the star shows a black flying eagle with a laurel wreath and thunderbolt and the same legend as the cross. Only reigning princes and Knights of St. John may wear any other order of eagle, which is the highest decoration in Prussia.

EAGLE, RED, ORDER OF THE. A Prussian order, founded in 1734 by the Margrave George Frederick Charles of Bayreuth, as a reorganization of the *Ordre de la Sincérité*. The order was raised in 1791 by Frederick William II to the rank of second in the monarchy. All the Knights of the Black Eagle were received into this new order, and it was afterward decreed that only those who had been decorated with the Red Eagle in the first instance could receive the Black. In 1810 two more classes were added to the order, and in 1830 the second class was subdivided into two. The badge consists of a white Maltese cross with red eagles between the arms, in the centre a golden plaque with the cipher F.W.R. and the motto *Sincere et constanter*. The ribbon is white, with two orange stripes.

EAGLE, JAMES PHILIP (1837-1904). An American legislator, born in Maury Co., Tenn. He served with distinction in the Confederate army from 1861 to 1865 and had risen to the rank of lieutenant colonel at the close of the war. In 1870 he became a Baptist minister, and he was president of the Arkansas State Baptist Convention for 20 years (1878-98) and also served as chairman of its executive board. He was a member of the convention which framed the constitution of Arkansas (1874) and served four terms in the State Legislature, being elected Speaker in 1885. He was Governor of Arkansas from 1889 to 1893.

EAGLEGROVE. A city in Wright Co., Iowa, 19 miles northeast of Fort Dodge, on the Chicago and Great Western and the Chicago and North Western railroads. (Map: Iowa, D 2). It is in an agricultural region, producing corn, oats, hogs, and cattle. The city contains a Carnegie library, a hospital, and railway shops. Eagle Grove was incorporated in 1882 and is governed by a mayor, elected biennially, and a unicameral council. The water works, comprising numerous artesian wells, are owned by the municipality. Pop., 1900, 3557; 1910, 3387.

EAGLE ISLE. See **ACHILL**.

EAGLE OWL. The name most often given in Europe to the great horned owl (*Bubo bubo*), representing a group of large, fierce owls of the Northern Hemisphere generally, of which the American great horned or hooting owl is a familiar example. They are characterized by a somewhat incomplete facial disk, two tufts of feathers (*horns* or *egrets*) of considerable size on the head, ears with small external openings, legs and toes covered with feathers, short, strong, curved bill, and long, curved, sharp claws. To this genus belong the largest of the nocturnal birds of prey. The eagle owl of Europe approaches in size (26 to 28 inches) the golden eagle and preys on quadrupeds such as hares, rabbits, and young deer, and on grouse and partridges. It seizes its prey with its feet and

seldom touches it with the bill till its struggles are over. It is an inhabitant of many parts of Europe and Asia, but it is rare in Great Britain. The eagle owl of America (*Bubo virginianus*), the great horned owl, is very similar to this species, but of inferior size. It does not scruple to attack wild turkeys and often succeeds in making them its prey. It is found in almost all parts of both North and South America and is not migratory. This sedentary habit has resulted in the fixing of variations and characters which have led to its separation into eight or more races. Eastern Asia has some allied species.

The habits of all these birds are essentially similar and differ from those of the smaller owls (see **OWL**) only in their greater strength and boldness. They lay two or three white eggs, but an East Indian species (*Bubo coromandus*) is remarkable in laying sometimes distinctly spotted eggs. In northern regions the eggs are laid in March or in February and often incubated amid violent snowstorms. This owl is often seen in menageries. Its note is a deep, loud, two-syllabled hoot, but is varied sometimes into a hoarse, neighing laugh. Consult: Dresser, *Birds of Europe* (London, 1879), and other ornithologies (see **BIRD**) for Old World species; Fisher, *Hawks and Owls of the United States* (Washington, 1893); Beebe, *Owls of the Nearctic Region* (New York, 1907); Dawson, *Birds of Washington* (Seattle, 1909); Slater and Hudson, *Argentine Ornithology* (London, 1888). See **PLATE OF OWLS**.

EAGLE PASS. A city and the county seat of Maverick Co., Tex., 169 miles west-southwest of San Antonio, on the Southern Pacific and the Mexican International railroads, and on the Rio Grande (Map: Texas, B 5). It is in a coal-mining, irrigation-farming, and stock-raising region, ships cattle, hides, and wool, and has lumber and brick yards. Being the port of entry for the Saluria district, it enjoys a flourishing international trade, which was important during the Civil War. The city has a fine Federal building. The commission form of government has been adopted. Pop., 1910, 3536.

EAGLE RAY (so called from the winglike shape of the pectoral fins). A large ray of the family *Myliobatidæ*, and especially *Myliobatis freminvillei* of the warmer parts of the Atlantic Ocean. In this genus the disk is broad and sharply angular in outline; the cephalic fins form a soft, convex appendage before the snout; the tail is long and slender, giving the name "whip ray" to some species. The habits and food are similar to those of sting rays. See **RAY**.

EAGLES, ORDER OF. A fraternal organization, founded in 1898 and having its general offices at Kansas City, Mo. In 1914 it included one grand aerie and 1545 subordinate aeries. There were 347,569 members in that year. The benefits dispersed from its organization to the close of 1913 amounted to \$10,797,549, and the disbursements for the fiscal year 1913 amounted to \$1,442,821.

EAGLE VULTURE. A vulturine sea eagle (*Gypohierax angolensis*), placed by some ornithologists between the eagles and kites and by others nearer the true vultures. It is a bird of prey of the West African coast region from Senegambia to Angola and also of a limited district near Zanzibar. It resembles a vulture

in appearance, especially in the shape of the head, beak, and the naked space about the eye, but in habits is essentially a fish-eating sea eagle. (See EAGLE.) It haunts the mangrove swamps of the estuaries, but retires to the forests farther up the streams for breeding purposes. It is 2 feet in length and beautiful, being snowy white, with black wings and tail.

EAGLEWOOD. See **ALGES WOOD**; **CALAM-BUCO**.

EAGRE. See **BORE**.

EAKINS, THOMAS (1844-1916). An American figure and portrait painter and sculptor. He was born in Philadelphia and studied at the Pennsylvania Academy and afterward at the Ecole des Beaux-Arts under Gérôme, also studying sculpture with Dumont. He was for years professor of painting in the Pennsylvania Academy, and he became a member of the National Academy of Design. He excels especially in draftsmanship, but in his forceful realism he often neglects pictorial qualities. In his portraits the personality of the sitter is finely rendered, but the backgrounds are cold and thin. Among the best are those of Louis Kenton, Cardinal Martinelli, Carroll Beckwith (1905), Dr. Gilbert L. Parker (1910), and P. Hayes Agnew (1913). His masterpiece is the "Clinic of Professor Gross" (Jefferson Medical College, Philadelphia), which excels from the realistic as well as from the pictorial point of view. Other good examples of his work are: "Chess Players" (Metropolitan Museum, New York); "The Cello Player" (Pennsylvania Academy of Fine Arts); "The Clinic of Professor Agnew" (University of Pennsylvania); "The Crucifixion" (Overbrook Seminary); "The Mother" (1910); "A Bohemian" (1913). He modeled the horses on the Brooklyn Soldiers and Sailors Monument and two reliefs on the Trenton Battle Monument.

EALDRED. See **ALDRED**.

EALING, el'ing. A town of Middlesex, England, about 9 miles west of St. Paul's Cathedral, London (Map: London, E 5). Charles Dibdin the popular song writer, Henry Fielding the novelist, and Lady Byron were long residents of Ealing, and it is the birthplace of Huxley. The town maintains a fine town hall, two public libraries, public baths, an art school, a hospital, an electric-lighting plant, and about 150 acres of park land. The population increased from less than 4000 in 1851 to 33,031 in 1901 (when it was incorporated) and 61,235 in 1911.

EAMES, emz, CHARLES (1812-67). An American lawyer and journalist, born at New Braintree, Mass., and educated at Harvard. In 1845 he was appointed to the Navy Department at Washington, where he soon afterward became associate editor of the *Washington Union*. He was sent by President Polk as special commissioner to negotiate a treaty with the Sandwich Islands. He was Minister to Venezuela during the administration of President Pierce. During his later years he ranked as an authority in admiralty and international law.

EAMES, amz, EMMA (1867-). An American soprano, born in Shanghai, China. She was brought to Maine at five and a year later began her piano studies in Boston. Her mother, who was an accomplished amateur singer, took care of her promising voice and later secured Madame Picciotti and Clara Munger as her teachers. From 1886 till 1889

she was a pupil of Marchesi, whose intimacy with Gounod secured her an engagement at the Grand Opéra to replace Patti as Juliet in Gounod's opera. She made an instantaneous success and during the two years in Paris sang also Marguerite and created Colombe in Saint-Saëns's *Ascanio* and the title part in *Zaire* by De la Nux. In 1891 she sang in London. There she married Julian Story, the portrait painter. In November of the same year she appeared at the Metropolitan Opera House in New York, and thereafter she appeared frequently in New York, London, Madrid, and Monte Carlo. Her repertoire includes rôles in French, Italian, German, and English. In 1907 she separated from Mr. Story and in 1911 was married to the baritone Emilio de Gogorza.

EAMES, emz, WILBERFORCE (1855-). An American librarian and bibliographer, born at Newark, N. J. In 1885 he became an assistant at the Lenox Library, New York City, and in 1893 librarian. Subsequent to the consolidation, in 1893, of the Lenox Library with the Astor and Tilden trust foundations, to constitute the New York Public Library, he was known as "Lenox librarian." He edited, among other works, a comparative arrangement (1882) of the King James and revised versions of the New Testament; vols. xv-xx (1885-92) of Sabin's *Dictionary of Books Relating to America*; a comparative edition of four Latin texts (with new Eng. trans., 1892; rev. ed., 1893) of Columbus' *Letter to Sanchez on the Discovery of America*; John Eliot's *Logick Primer*, 1672 (1904); *Humble Request of Gov. Winthrop and the Company*, 1630 (1905); and he prepared *Early New England Catechisms: A Bibliography* (1898).

EAMES, WILLIAM S. (1857-1915). An American architect, born at Clinton, Mich., and educated at Washington University, at the Ecole des Beaux-Arts, Paris, and at Rome. After 1862 he was a practicing architect at St. Louis, Mo., where he was also deputy commissioner of public buildings in 1881-83. He was the United States representative at the International Congress held at Madrid, Spain, in 1904, and was president of the American Institute of Architects in 1904-05.

EAR (AS. *ear*, Ger. *Ohr*, Goth. *ausō*, OChurch Slav. *ucho*, Lith. *ausis*, Lat. *auris*, Gk. *oûs*, *ous*,

FIG. 1. THE ORGAN OF HEARING (RIGHT) FROM IN FRONT.

ear). The organ of hearing as it exists in man and the mammalia. It is composed of three parts: the external ear; the middle ear, or tympanum; and the internal ear, or labyrinth.

The External Ear. This consists of two portions: the auricle, or pinna (the part popularly recognized as the ear); and the auditory canal, or external auditory meatus. The auricle, on its outer or more exposed surface, presents various eminences and depressions resulting from the form of its cartilaginous framework. The rim, called the helix, incloses a narrow groove—the fossa of the helix—of which the inner boundary is a longitudinal ridge, parallel to the helix and known as the antihelix; usually the antihelix is divided above into two ridges which inclose a shallow depression termed the fossa of the antihelix. The large central hollow containing in its bottom the opening of the auditory canal is called the concha. In front of the external auditory meatus there is a pointed process directed backward and known as the tragus; corresponding to this is the similar process behind the meatus and pointing forward, termed the antitragus. The low-

FIG. 2. THE AURICLE, OR PINNA.

est and pendulous portion of the auricle is called the lobule.

The intrinsic muscles of the auricle are, in man, functionless. Besides these, there are three extrinsic muscles, passing from the adjacent portions of the scalp to the ear; they are the *attollens aurem*, *attrahens aurem*, and *retrahens aurem*; they are rudimentary in man, though occasional individuals are able to contract them and thus perform perceptible movements of the ear at will.

The auditory canal is slightly arched and passes inward and a little forward from the concha to the tympanum; it is about $1\frac{1}{4}$ inches long; at its outer end there are a number of ceruminous glands, which furnish an adhesive, yellow, and bitter substance, the ear wax (see CERUMEN), which serves to protect the ear from insects, dust particles, etc. The canal is partly cartilaginous and partly osseous; the osseous portion consisting in the fœtus of a bony ring, across which the drum membrane is stretched, and in many animals remaining persistently as a separate bone. The entire canal, as well as the outer surface of the drum membrane, is lined with skin.

The Middle Ear. This is a small, irregular cavity in the temporal bone, lined with a mucous membrane, the epithelium of which is ciliated like that of the Eustachian tube and pharynx, with which it is continuous. It contains three ossicles—the malleus (hammer), incus (anvil), and stapes (stirrup)—joined by ligaments to form a small chain attached to its outer end, by the handle of the malleus, to the drum membrane, and at its inner end, by the base of the stapes, to the membrane

covering the *fenestra ovalis*. The muscles of the middle ear are the *tensor tympani* and the *stapedius*. The former arises from the under-surface of the petrous portion of the temporal

FIG. 3. SMALL BONES OF THE EAR.

bone and is inserted into the handle of the malleus. The latter takes its origin from the hollow conical eminence, termed the pyramid, which lies behind the *fenestra ovalis* and is inserted into the neck of the stapes; by pulling the neck backward it probably compresses the contents of the vestibule. The Eustachian tube, into which the tympanic cavity opens anteriorly, is about $1\frac{1}{2}$ inches in length, and passes downward, forward, and inward to its opening in the pharynx. It is partly bony, but chiefly cartilaginous. It serves for the escape of mucus from the middle ear into the pharynx; also by allowing free passage of air in and out of the tympanum, it renders the pressure upon the inner surface of the drum membrane equal to the atmospheric pressure upon its outer surface. Upon the inner wall of the tympanum there are two openings: the *fenestra ovalis*, mentioned above, leading into the vestibule; and the *fenestra rotunda*, covered by a membrane, leading into the cochlea.

The Internal Ear, or Labyrinth. This consists of three parts: the vestibule, the cochlea, and the semicircular canals. The vestibule is a small central cavity communicating by openings in its posterior wall with the semicircular canals; anteriorly the cochlea enters it by a single opening, the beginning of the *scala vestibuli* described below. On its outer wall is the *fenestra ovalis*, and on its inner there are a num-

FIG. 4. THE OSSEOUS LABYRINTH, LAID OPEN AND ENLARGED.

ber of minute orifices for the entrance of the filaments of the auditory nerve. The cochlea (Lat., snail shell) is situated in front of the vestibule. It is a spiral canal wound around a bony axis, termed the modiolus, which is per-

forated at its base for the entrance of the filaments of the cochlear portion of the auditory nerve. The interior of the cochlea is subdivided by an osseous membranous partition, the *lamina spiralis*, into two passages—the *scala vestibuli*,

FIG. 5. THE COCHLEA, ENLARGED.

opening into the vestibule, and the *scala tympani*, the communication of which with the tympanic cavity (the *fenestra rotunda*) is covered by a membrane as described above; the two *scalæ* communicate at the apex of the cochlea by an opening called the helicotrema. Between the two *scalæ* there is a third space, termed the *scala intermedia*, which contains the terminations of the filaments of the auditory nerve in a complicated arrangement of peculiarly formed neuro-epithelial cells termed collectively the organ of Corti. (See AUDITORY NERVE.) The semicircular canals are three in number and open at both ends into the vestibule. They vary in length, and, notwithstanding their name, each is considerably more than a semicircle, the superior vertical canal being the longest. Their average diameter is about one-twentieth of an inch, the extremities of each canal exhibiting a slight dilatation called an ampulla. Each canal lies in a different plane, very nearly at right angles to the planes of the other two; hence their names of the superior vertical, the inferior vertical, and the horizontal canals. According to a later nomenclature they are named respectively the perpendicular, oblique, and external semicircular canals. We now turn to the membranous labyrinth. The membranous and osseous labyrinths have the same shape, but the former is considerably smaller than the latter, a fluid, termed the perilymph, intervening in some quantity between them. At certain points the membranous is firmly adherent to the osseous labyrinth. The vestibular portion consists of two sacs, an upper and larger one, of an oval shape, termed the utricle, and a lower and smaller one, of a more globular shape, called the sacculus.

The membranous semicircular canals resemble in form and arrangement the osseous canals which inclose them, but are only one-third of the diameter of the latter. The membranous labyrinth is filled by a fluid which is termed the endolymph; and in certain spots, especially at the terminations of the vestibular nerves, there are, suspended in the somewhat gelatinous endolymph, crystals of calcium carbonate known as otoliths, i.e., ear stones, which are supposed to intensify the impression of the sound waves upon the nerve endings.

We now proceed to consider the different functions of the various parts of the ear.

The External Ear. A true auricle exists only in the mammalia, and in this class it varies from little more than an irregularly shaped cartilaginous disk, with little or no motion, as in

man and the quadrumana, to an elongated, funnel-shaped ear trumpet, moveable in all directions by numerous large muscles, as in the horse, the rabbit, etc. The mode in which we see it employed in animals in which it is highly developed sufficiently indicates that its main function is to collect the sound waves that fall upon it, and to direct and concentrate them upon the drum membrane.

The Middle Ear. The vibrations of the tympanic membrane are transmitted through the ossicles and the membrane covering the *fenestra ovalis* to the perilymph. The pressure in the tympanic cavity is kept the same as that of the atmosphere by the Eustachian tube. Whenever the drum membrane is too tightly stretched, by increase or decrease of pressure within the middle ear, it cannot vibrate freely, and hearing is impaired. This often occurs as a result of acute and chronic inflammation of the pharynx, when the swelling of the mucous membrane closes the Eustachian tube, producing the so-called throat deafness.

The Internal Ear. Sound is conducted to the labyrinth either by the external and middle ear, as described above (air conduction), or through the bones of the head (bone conduction); normally air conduction is better than bone conduction. In diseases of the middle ear or in obstructions of the external auditory meatus air conduction is not so good as bone conduction. Advantage is very frequently taken of this fact in the differential diagnosis between diseases of the internal ear and those of the middle or of the external ear. To test the air conduction a vibrating tuning fork is held close to the ear; to test the bone conduction the handle of the tuning fork is brought in contact with the teeth, forehead, mastoid process, etc., in turn. As stated, it is the base of the stapes that communicates the vibrations to the perilymph; this would be impossible but for the existence of the *fenestra rotunda*, which acts as a vent for the vibrations of the perilymph and endolymph; every time the membrane of the *fenestra ovalis* bulges in, that of the *fenestra rotunda* bulges out, and vice versa. The internal ear also performs the most essential function connected with hearing: that of perception of auditory impressions by means of the cochlear and vestibular terminations of the auditory nerve. It remains for us now to consider the function of the semicircular canals. It is now a generally recognized fact that they are not connected with the sense of hearing. They have to do with the maintenance of the equilibrium of the body. The fact was established by Ewald in 1892. To maintain equilibrium in the various positions of rest and especially in locomotion, the accurate coördination of a great many muscles is necessary. The cerebellum is the organ which sends out the nerve impulses to these muscles; this action is an unconscious one, being purely reflex in character. The afferent impulses which bring about these reflexes are, besides others of secondary importance, the ones conveyed to the cerebellum from the semicircular canals. When these canals are removed in animals, or when they are diseased in man, as in Menière's disease, there are invariably profound disturbances of equilibrium, the subject being unable to stand or even to sit, without swaying or falling, to say nothing of such complicated acts as walking, jumping, etc.

The range of hearing, like that of vision, varies remarkably in different persons. Some persons

are insensible to sounds which others can readily hear. The ordinary range of human hearing includes, according to Wollaston, more than nine octaves. Technically stated, the normal ear perceives vibrations as musical notes from 16 vibrations per second to about 32,500. The sensation of sound, like that of light, frequently lasts longer than the exciting cause. We have familiar proof of this fact in the noise which remains in the ears after a long journey in a coach or railway car; and this fact was clearly demonstrated by Savart, who found, in his experiments on toothed wheels, that the removal of one tooth did not produce any interruption of the sound.

DISEASES

The diseases of the ear are divided into diseases of the auricle, diseases of the external auditory . . . diseases of the middle ear, and diseases . . . mastoid process.

Diseases of the Auricle. Under this head are included congenital malformations of the auricle, such as deformities, appendages and supernumerary growths, wounds, injuries, cutaneous diseases, inflammatory processes attacking the cartilage, abscesses, erysipelas, and tumors.

Diseases of the External Auditory Apparatus. Under this head are included furuncle or boil, cellulitis, impacted wax, foreign bodies in the ear, bony growths, and wounds or other injuries of the drum membrane.

The conditions mentioned in the two foregoing divisions need no more than individual mention, either because their treatment is similar to that of similar conditions elsewhere in the body, or because their titles suggest the remedies appropriate.

Diseases of the Middle Ear. 1. *Tubal catarrh* is a congestive condition of the Eustachian tube, leading from the throat to the middle ear. The result of this affection is closure of the tube, with deafness and constant noises heard, with a sense of fullness in the head. Inflation of the tube is the treatment, with possibly subsequent dilatation and treatment with medicated vapors. 2. *Acute catarrhal inflammation of the middle ear* is an affection of the superficial structures that line the middle ear, with the production of seropus in such quantity that often the ear drum bulges and may even burst. Incision is necessary to prevent bursting and to secure drainage. The malady may complicate measles or catarrh of nose and throat, or may be caused by the introduction of fluid through the Eustachian tube while bathing. In young children the disease may appear suddenly at night, with a temperature of 102° to 104°, and a period of intense suffering, relieved by rupture of the drum and pouring out of a little serous discharge that stains the pillow. Rise of temperature may continue on the following day, together with deafness and noises in the ear. As a rule, the cases terminate favorably without treatment. Suppuration may occur involving the mastoid cells. The treatment is directed first to relief of pain, by using a saline cathartic and an opiate. Local bloodletting by means of the artificial leech and the application of dry heat may abort an attack. If these measures fail to abort it, incision of the drum must be made, and the ear must be syringed and dressed antiseptically. 3. *Chronic catarrhal inflammation of the middle ear* is either of the hypertrophic or of the hyperplastic variety. In the

hypertrophic variety there is a swelling of the lining membrane of the tympanum due at first to chronic venous congestion, after which occurs hypertrophy of the elements of the tissue lining the cavity. Fibrous layers appear, and calcareous deposits may ensue. The drum membrane, the ossicles, the ligaments, and the walls of the Eustachian tubes share these changes. Exudate of serum or seromucus collects in the cavity. Among the causes for this condition are repeated attacks of acute rhinitis, the presence of adenoid tissue in the vault of the pharynx, impairment of the general health, and the abuse of alcohol. The results are impaired hearing, whistling or buzzing or crackling noises in the ear, and occasional neuralgic pains, especially upon swallowing. Entire recovery can never be promised in these cases, but treatment by the aural surgeon, of a technical and intricate nature, may cause vast improvement and avert total deafness. Chronic hyperplastic otitis media may develop from the hypertrophic form and is characterized by an appearance of firm and fibrous new tissue, diminished secretion, thickening of the walls of the supplying blood vessels, with a resulting sclerosis. The symptoms resemble closely those of the . . . variety, with the addition of . . . the early stages and a marked neurasthenic or even melancholic condition, due partly to the temperamental state which invited the attack, partly to the fatigue of the higher cerebral centres resulting from repeated efforts to hear conversation. The prognosis for recovery is very grave, and the disease is less amenable to treatment than any other aural trouble. Treatment is directed by the aural surgeon towards the relief of the rigidity of the ossicular chain, by inflation, exercise of the tubal muscles, the use of the Eustachian bougie, and of the . . . and several operative procedures. . . . acid or pilocarpine may be desirable for internal use. 4. *Acute purulent otitis media* most frequently follows an infectious disease, such as scarlatina, la grippe, smallpox, cerebrospinal meningitis, pneumonia, etc. Pus forms behind the drum head and may dissect its way into the neighboring soft parts or may invade the mastoid. The prominent symptoms are very severe pain deep within the ear, a temperature of 101° or 103°, severe general headache, and great depression. Invasion of a sinus may ensue, and pyæmia may result, accompanied by a higher temperature, delirium, convulsions, and paralysis. Immediate and vigorous operations . . . are employed by an aural surgeon . . . only treatment. 5. *Chronic purulent otitis media* occurs as a sequel to the acute form and, like it, is due to tissue necrosis. Discharge from the ear is the only prominent symptom, and one which should always suggest the necessity for competent medical advice. 6. *Otitis media purulenta residua* is a term applied to a class of cases in which a former purulent inflammation has resulted in a permanent destruction of some of the tympanic structures. It may be either acute or chronic. The aural surgeon alone can differentiate this condition and advise regarding the antiseptic irrigation necessary or the removal of dead bone which may have become imperative. See OTITIS MEDIA.

Diseases of the Mastoid Process. Inflammation of this process may result from extension of a similar process from the middle ear. A chronic suppurative otitis media is the most fre-

quent cause of acute mastoiditis. It may follow exposure to cold, a traumatism, or general tubercular or syphilitic infection. A destruction of the osseous tissue results. The most prominent symptom is intense pain over the mastoid process especially at night, a temperature of 99.5° to 101.5° , difficulty in moving the head from side to side, and tenderness upon deep pressure over the tip of the mastoid. But slight constitutional disturbance is present. Involvement of a venous sinus with the production of an infectious thrombus may occur; emboli may develop and lodge in various viscera; diffuse meningitis may complicate the disease, with resulting paralysis; or the rarer cerebral abscess may follow. The diagnosis of mastoid disease is a matter of difficulty for any but an expert observer, although two signs are very reliable. These are local tenderness upon deep pressure over the mastoid region, and a depression or sagging of the superoposterior wall of the canal, close to the tympanic ring. Besides these signs, a localized tumefaction of the posterosuperior canal wall (if it occur) is very indicative of mastoid involvement. Many other symptoms present themselves, similar to those enumerated in the consideration of other diseases afflicting the ear. The prognosis is always grave. The treatment consists in rest in bed, fluid diet, catharsis, extensive incision of the drum membrane, if seen early, together with irrigation of the canal and the employment of the Leiter coil, by which cold is applied to the whole mastoid portion of the temporal bone. Drugs are given to relieve pain. After 48 hours have passed without amelioration, operative interference is necessary. In such a case the surgeon makes an incision through the soft parts back of the ear and with mallet and chisel makes an opening through the cortex into the mastoid cells, whence all softened bone tissue is removed with the sharp spoon.

See AUDITION; ACOUSTICS, and the authorities there referred to.

EAR, COMPARATIVE ANATOMY OF THE. The question of the hearing powers of animals is still a subject of dispute, and we cannot say positively whether the lower animals are conscious of sound waves, as such, or not. But if we bear in mind that the human ear is not merely an organ of hearing, but is also the means by which we determine our position (in other words a positional organ), then we are justified in saying that many invertebrates have ears, even though we deny them the sense of hearing.

Positional and Chordotonal Organs. Positional organs as found in the simplest conditions are minute balls of mineral matter suspended in a flexible club-shaped body and are known as sense clubs. They are formed on the margin of the bell in many medusæ. In some cases they are surrounded by long hairs against which they strike when they move. In a still more advanced condition they are situated in a depression, and the surrounding tissue grows over and about them, so as to inclose them in a cavity. It is but a step from such a condition to the form of positional organs, called otocyst, which occurs

in many invertebrates. An otocyst is a spherical cavity lined with cilia and containing one or more balls of mineral matter called otoliths. The otocyst is specially and fully innervated, the stimuli coming from the movements of the otolith against the cilia, accompanying changes in the position of the body. There is no evidence to show that such organs are capable of detecting sound waves. Otocysts occur in medusæ, many kinds of worms, numerous mollusks, a few echinoderms, and the higher crustacea. In the latter the vesicles often remain open, and the otoliths are grains of sand; the vesicles are lined with delicate hairs, some of which are actually attached to the otoliths. Insects have no otocysts, but in their place we find remarkable structures known as chordotonal organs, which lie in the integument of various parts of the body. They are largest and most highly developed in grasshoppers, locusts, and crickets, and two or four of them are very large and are known as the tympana. They lie on the sides of the abdomen or on the tibiae of the forelegs. Chordotonal organs seem to be particularly adapted for the detection of sound waves, but how they can serve as positional organs is not clear.

Primitive Auditory Organs. Turning now to vertebrates, we find a general agreement with the structure of the human ear, even in fishes, although in details and proportions there is much variety. In the cyclostomes it is probable that there is no real sense of hearing, for the semi-circular canals are the only well-developed parts of the ear, and these are believed to be specially concerned with the positional function. Whether other fishes actually hear sounds is still a disputed question. The cochlea is, in fishes, simply a small knoblike appendage of the sacculus and shows none of the complexity of the mammalian cochlea. In most fishes large otoliths are present in the labyrinth, and in many fishes there is direct connection between the ear and the air bladder by means of a chain of small bones. Certain experiments (1902) by Dr. G. H. Parker of Harvard apparently demonstrate the actual recognition of sounds by some fishes, and that this recognition is dependent upon the uninjured condition of the ears and auditory nerves. In Amphibia a certain sensory zone near the base of the lagena represents the origin of the cochlea, and this part of the ear increases in complexity as we pass upward through reptiles to birds and mammals. Even in crocodiles and birds, however, there is no organ of Corti in the cochlea, and there is a single bony columella instead of the three auditory ossicles of mammals. In many respects the ears of monotremes are noticeably like those of the Crocodilia. Fishes, amphibians, and most reptiles have no outer ear, and the pinna is only found in certain mammals. The external ear is first noticeable in certain lizards, where it is represented by a simple fold of skin. In the mammals the lagena is greatly reduced, and the cochlea is highly developed, showing two to five spirals.

EARCOCKLES, PURPLES, or PEPPERCORN. A disease in wheat caused by a nematode worm (*Tylenchus tritici*). This worm is yellowish white, slender, tapering towards the tail, and more suddenly attenuated to a point at the head. It finds its way to the flowers; the infected grains become dark green, then black, rounded like small peppercorns, and furrowed on the surface; the glumes spread open, and the awns become twisted; the grains are filled with a white cottony substance which consists of myriads of the nematodes. The disease has recently been reported in the United States.

EAR FUNGI. An order (Auriculariales) of Basidiomycetes characterized by spoon-bearing structures which resemble ears. These earlike growths are found on bark, board fences, etc., a very common form being seen on old stems of elder. When moist, the ears are gelatinous and brightly colored. When dry, they become hard, gray, wrinkled, and hairy.

EAR OF DIONYSIUS. See DIONYSIUS, EAR OF.

EARL (AS. *eorl*, Icel. *earl*, Dan. *jarl*, earl, OS., OHG. *erl*, man, warrior). A title of the British nobility, third in rank under the princes of the blood royal, next to a marquis, and above a viscount. In Anglo-Saxon times the word denoted the primitive noble by birth of the first settlement, the *nobilis* of the Old Germans, as distinguished from the *eorl*, or common freeman. From this class the magistrates, priests, and kings were chosen. But with the development of the royal power in England, and consequently of thanehood, a nobility by service, the *eorl* sank one degree in the social scale and was merged into the class of thanes.

In the later Saxon period the word *eorl* changed its significance, being used for *ealdorman*. This was an administrative officer, the chief magistrate of a shire or cluster of shires. He was originally a viceroy, the subjected king of a conquered district or one of his family, or a near kinsman of the overking (*ætheling*). The office might be hereditary, but it tended to become appointive. The ealdorman was appointed in the general assembly of the nation, and, even where the office was hereditary, the consent of king and nation was necessary. He sat with the bishop in the folk moot of the shire, declaring the secular law, as the bishop did the spiritual. He was head of the military levy of the shire and exercised the royal police jurisdiction.

To maintain his dignity, he received a third of the profits of the administration of justice in the shire. After the Danish incursions the office became an upper governorship, and the incumbent was frequently changed. The Danish word *jarl*, English *earl*, was applied to it. Canute divided England into four earldoms, and there were five under Edward the Confessor.

William the Conqueror, while retaining all the dignity of the office, reduced its power by making it hereditary and giving its judicial functions to the sheriff or vicecomes (vice earl), his own appointee. The great earldoms were gradually broken up, and the holdings of the earls scattered through different shires. William bestowed the title sparingly, but under his successors, especially during the civil war of Stephen and Matilda, it was lavishly given.

This ceased with Henry II. The title corresponded with the French *comte*, an earl's wife being always called countess. The office of earl remained essentially a county office, usually taking its name from the shire. The third penny of the pleas was still granted to show this connection and does not disappear until the thirteenth century, when its place is taken by a fixed sum called creation money. The earl was the highest in rank of the nobility until Edward III created a duke in 1357 and Richard II a marquis in 1385. He had a hereditary right to a seat in Parliament.

The title was originally conferred by investiture, the King himself girding on the sword of the county, and the temporal authority in the county). Edward III, wishing to avoid the hatred caused by his father's investiture of favorites, first began the custom of creating earls in Parliament, and also that of investiture by charter or letters patent. Now only the last-named method prevails. The dignity of an earl is not partible, and, although it may descend through a woman, it reverts to the crown in case of coheirs. In the fourteenth century limitations to heirs male of the body became the rule.

The number of earls varies in the different periods of English history. In the Middle Ages there were very few earls, but the Stuarts greatly increased the number, especially James I, who sold the dignity for £20,000. Now there are over 200 earls in the United Kingdom, and the territorial nature of the dignity has so far disappeared that they even take the titles from their names, as did Earl Grey and Earl Russell. The earl's coronet is a gold circlet, with light spikes, on the tips of which are pearls alternating with strawberry leaves. The eldest son takes the courtesy title of the family, usually of viscount, younger sons are "The Honorable," and all daughters are "ladies," the title being prefixed to the given name for life, unless the title is a title.

Bibliography. For the earliest period the sources are the Anglo-Saxon laws, in the editions of R. Schmid (Leipzig, 1832), B. Thorpe (Record Commission, 1840), and, best of all, F. Liebermann (Halle, 1898 et seq.). Compare Schmid's *Glossary*, sub "Eorl," and Liebermann's *Commentary*, vol. ii. Among modern authors are J. M. Kemble, *Saxons in England* (London, 1876), and K. Mauer, *Kritische Ueberschau der deutschen Gesetzgebung* (Munich, 1853-56). The sources for the period since the Conquest are best found in the letters patent and other material published in *Reports from the Lords' Commission on the Dignity of a Peer of the Realm* (London, 1820-29), especially in the third report. Based on this is Sir Harris Nicholas, *Historic Peerages of England* (continued by W. Courthope, ib., 1857), sub "Earl." Good brief modern accounts for the entire period are those of William Stubbs, *Constitutional History* (Oxford, 1894), vol. i, pp. 125-126, 168-169, 176-178; R. Gneist, *History of the English Constitution*, trans. by P. A. Ashworth, vol. i, pp. 138-141; see p. 140, note, for the older literature (New York, 1886). R. Selden, *Titles of Honor* (London, 1614), is still useful.

EARLE, ALICE MORSE (1853-1911). An American writer on Colonial history. She was born in Worcester, Mass., and graduated at the Worcester High School. In 1874 she was married to Henry Earle. She wrote voluminously on the social and domestic history of Colonial

New England and New York and in her various books presents a mass of quaint and interesting information. Her publications include: *The Sabbath in Puritan New England* (1891); *China Collecting in America* (1892); *Customs and Fashions in Old New England* (1893); *Life of Margaret Winthrop* (1894); *Colonial Dames and Goodwives* (1895); *Costume of Colonial Times* (1895); *Colonial Days in Old New York* (1896); *Curious Punishments of Bygone Days* (1897); *Home Life in Colonial Days* (1898); *Child Life in Colonial Days* (1899); *Stage Coach and Tavern Days* (1900); *Old Time Gardens* (1901); *Sun-Dials and Roses of Yesterday* (1902); *Two Centuries of Costume in America* (2 vols., 1903).

EARLE, FRANKLIN SUMNER (1856-). An American botanist and . . . at Dwight, Ill., and educated . . . of Illinois and at the Alabama Polytechnic Institute. Between 1894 and 1896 he served in several experiment stations and as assistant pathologist in charge of the mycological herbarium of the United States Department of Agriculture, and he was professor of biology at the Alabama Polytechnic Institute from 1896 to 1901. As assistant curator in charge of the mycological collection of the New York Botanical Garden he visited Jamaica and Cuba in 1903, and in the same year he conducted researches in Porto Rico for the government. He was director of the Estación Central Agronómica of Cuba in 1904-06 and in 1908 became consulting agriculturist to the Cuban-American Sugar Company. In 1906-07 he was president of the Botanical Society of America. He is author of *Southern Agriculture* (1908).

EARLE, JOHN (1824-1903). An English philologist and divine. He was born at Elston and was educated at Oxford, where he was professor of Anglo-Saxon from 1849 to 1854 and again after 1876. He was appointed rector of Swanswick in 1857, prebendary of Wanstrow in 1871, and became professor of Anglo-Saxon in Oxford University in 1876. His principal publications are: *Gloucester Fragments* (1861); *The Philology of the English Tongue* (5th ed., 1892); *A Book for the Beginner in Anglo-Saxon* (3d ed., 1884); *Anglo-Saxon Literature* (1884); *Hand-Book to the Land-Characters and other Saxon Documents* (Oxford, 1888); *The Deeds of Beowulf* (1892); *Two of the Saxon Chronicles Parallel, with Supplementary Extracts from the Others* (Oxford, 1865; rev. ed., with introduction and glossary by Plummer, ib., 2 vols., 1892-99); *English Prose: Its Elements, History, and Usage* (1890); *The Psalter of 1539: A Landmark in English Literature* (1894); *A Simple Grammar of English Now in Use* (1898); *The Alfred Jewel* (1901).

EARLE, MORTIMER LAMSON (1864-1905). An American classical scholar. He was born in New York and received the A.B. from Columbia College in 1886 and his doctorate in 1889. From 1889 to 1895 he was instructor in Greek in Barnard College; he was then appointed associate professor of Greek and Latin in Bryn Mawr; from 1898 to 1900 he was lecturer in Greek in Columbia University; and in 1900 he became professor of classical philology in Barnard College, New York. His literary work included the editing of Euripides' *Alceste* (1895); Sophocles' *Edipus Tyrannus* (1900); and Euripides' *Medea* (1904). His numerous contributions to learned periodicals were collected in *The Classi-*

cal Papers of Mortimer Lamson Earle, with a Memoir (New York, 1912). He was a contributor to the first edition of the NEW INTERNATIONAL ENCYCLOPEDIA.

EARLE, PLINY (1809-92). An American psychiatrist, born at Leicester, Mass. He received his medical education at the University of Pennsylvania, graduating in 1837; was a resident physician . . . Asylum for the Insane, Frankford, Pa., from 1840 to 1844; superintendent of Bloomingdale Asylum, New York City, from 1844 to 1853; visiting physician to the New York City Asylum, Blackwell's Island, from 1853 to 1864; professor of materia medica and psychology in the Berkshire Medical Institution at Pittsfield, Mass., from 1863 to 1864; and superintendent of the State Lunatic Hospital, Northampton, Mass., from 1864 to 1885. He published: *A Visit to Thirteen Asylums for the Insane in Europe* (1841); *Blood-letting in Mental Disorders* (1854); *Psychologic Medicine: Its Importance as a Part of the Medical Curriculum* (1867); *The Psychopathic Hospital of the Future* (1867); *Prospective Provision for the Insane* (1868); *Curability of Insanity* (1877).

EARLE, THOMAS (1796-1849). An American lawyer. He was born at Leicester, Mass., but when young settled in Philadelphia. He was a member of the Philadelphia Constitutional Convention of 1837. By advocating the extension of the right of suffrage to colored men he antagonized many members of the Democratic party, and in 1840 the Liberty party made him their candidate for Vice President. Subsequently he left politics for literary work and published: *Essay on the Penal Law; Essay on the Right of States to Alter and Annul their Charters; Treatise on Railroads and Internal Communications* (1830); *Life of Benjamin Lundy* (1874).

EARLE, WILLIAM (1833-85). An English soldier. He was born in Liverpool, was educated at Winchester, entered the army in 1851, and served with great gallantry in the Crimean War. He became colonel in 1868 and from 1872 to 1876 acted as military secretary to Lord Northbrook, Viceroy of India. He was commander of the garrison of Alexandria during Lord Wolseley's campaign against Arabi Pasha and in 1884 was division commander in the expedition dispatched to the aid of General Gordon at Khartum. He was killed while leading his detachment against Arab intrenchments at Kirbekan (Feb. 10, 1885).

EARLHAM COLLEGE. An institution of higher learning founded in 1859 by Orthodox Friends at Richmond, Ind. It succeeded a school of advanced grade which was opened for students in 1847. The college is educational. It is located on a tract of 120 acres, adjoining the western limits of the city of Richmond. The campus has an area of 40 acres, is shaded by native forest trees, and is tastefully laid out with walks and drives. There are . . . on the campus: Lindley Hall, Pauley Hall, Edwin S. Bundy dormitory, the library, the astronomical observatory, the gymnasium, and the central heating and lighting plant. The college grants only two bachelor's degrees, B.A. and B.S. The degree of M.A. is granted on the basis of liberal culture rather than specializing. The endowment amounts to about \$750,000, and the value of the college grounds and buildings to about \$375,000. The annual income is about \$140,000. The total number of students

in the collegiate year 1913-14 was 413, and the instructors numbered 31. The library⁴ contains about 20,000 volumes. The president of the College in 1914 was Robert Lincoln Kelly, Ph.M., LL.D.

EARLINGTON. A city in Hopkins Co., Ky., 54 miles south of Evansville, Ind., on the Louisville and Nashville Railroad (Map: Kentucky, C 5). It is in the centre of a coal-mining region and has extensive manufactures of coke. Under a charter of 1897 its government is vested in a mayor, elected for a term of four years, and a unicameral council of six members. There are two public libraries. Pop., 1900, 3012; 1910, 3931.

EARL MARSHAL. See MARSHAL.

EARLOM, or LOM, RICHARD (1743-1822). An English mezzotint engraver. He was born in London and studied there under Cipriani. In mezzotint he made some innovations in the use of the point, which gave delicacy to his method, and established his fame by fruit and flower pieces after J. van Huysum. He engraved also after Reynolds, Beechey, Hogarth, and the Dutch and Italian masters. His most important work was the reproduction of 300 drawings of Claude Lorrain in the Duke of Devonshire's collection, known as the *Liber Veritatis* (1777-1819).

EARLY, JOHN (1786-1873). An American bishop of the Methodist Episcopal Church South, born in Bedford Co., Va. He entered the Methodist ministry in 1807. It is said that his first religious work was among the slaves of Thomas Jefferson. He was one of the founders of Randolph Macon College and was for years president of its board of trustees. In 1846 he was elected book agent of the Methodist Episcopal Church South and in 1854 one of its bishops.

EARLY, JUBAL ANDERSON (1816-94). An American soldier, prominent on the Confederate side in the Civil War. He was born in Franklin Co., Va., graduated at West Point in 1837, served in the Seminole, or Florida, War of 1837-38, and resigned from the army to take up the practice of the law at Rocky Mount, Va., in July, 1838. In 1841-42 he was a member of the Virginia House of Delegates, and from 1842 to 1847 and again from 1848 to 1852 he held the position of commonwealth attorney. During the Mexican War he was major of a regiment of Virginia volunteers from January, 1847, to August, 1848. On the approach of the Civil War he was strongly in favor of the maintenance of the Union, and in the Virginia Convention of 1861 he strenuously opposed the adoption of the ordinance of secession; but, the ordinance having passed, he threw in his lot with his State and entered the Confederate army as colonel of the Twenty-fourth Regiment of Virginia Infantry. He commanded a brigade at the first battle of Bull Run, rendering effective service to his side at a critical part of the battle: was promoted soon afterward to be brigadier general; took a prominent part in the battle of Williamsburg, May 5, 1862, where he was seriously wounded; and distinguished himself in the second battle of Bull Run and in the battle of Antietam. At Fredericksburg, on Dec. 13, 1862, he commanded a division, and during the battle of Chancellorsville he commanded the right wing of General Lee's army, stationed at Fredericksburg, which was opposed to the Federal General Sedgwick. In January, 1863, he was promoted major general. He commanded a division of Lee's army at Get-

tysburg. Detached from that army in June, 1864, to operate against the Federal forces in the Shenandoah valley, Early, who had been commissioned lieutenant general May 31, repelled an attack of Hunter at Lynchburg on the 18th and forced that officer to the upper Potomac. The valley thus being left open, he advanced to Winchester, drove the Federal General Sigel to Maryland Heights, crossed the Potomac on July 6, levied \$20,000 on Hagerstown and \$200,000 on Frederick City, and on the 9th defeated Gen. Lew Wallace at Monocacy Junction. On the 11th he threatened the city of Washington, which was in a state of consternation, and which by a prompt attack he would probably have taken; but, a strong Federal reinforcement having arrived, he withdrew without serious molestation and retired up the Shenandoah valley. Towards the latter part of the month he again drove across the Potomac the Federal forces opposed to him, and in addition sent a cavalry detachment into Pennsylvania under McCausland, who occupied Chambersburg on July 30 and, in default of a ransom of \$100,000 in gold, burned the town in accordance with Early's orders. From August to November he contended against Sheridan, then in command of the Federal army of the Shenandoah, for the possession of the Shenandoah valley. He was finally defeated by superior numbers at Opequon Creek, near Winchester (September 19), and Fisher's Hill (September 22). On October 19 he surprised the Federals at Cedar Creek, but the timely arrival of Sheridan turned the fortunes of the day, Early's forces being routed. In March, 1865, Early was defeated by Custer at Waynesborough and was removed from command by Lee. By many military critics he is placed below only Lee and Jackson in the list of Confederate generals. After the war he lived for a short time in Canada, but in 1867 returned to Virginia, practiced law there for a time, then was associated with General Beauregard in the management of the Louisiana Lottery at New Orleans, and passed his last years in Virginia. He steadfastly refused until his death to take the oath of allegiance to the United States. General Early was for a time president of the Southern Historical Society. Besides several addresses on military subjects, he published *A Memoir of the Last Year of the War for Independence, in the Confederate States of America* (1867). For an account of General Early's operations in the Shenandoah valley, consult: Johnson and Buel (ed.), *Battles and Leaders of the Civil War*, vol. iv (4 vols., New York, 1887); Pond, *The Shenandoah Valley in 1864* (ib., 1883), in the "Campaigns of the Civil War Series"; and articles by Long and Daniel in vol. xviii and vol. xxii, respectively, of the *Southern Historical Society Papers* (Richmond, 1890, 1894).

EARLY ENGLISH. The term generally applied to the earliest phase of Gothic architecture (q.v.) in Great Britain. It is really a transitional style, through which English church architecture passed in its development from the Anglo-Norman into the more truly Gothic style known as the Decorated (q.v.). Broadly speaking it covered the century from 1175 to 1275. Its chief characteristics are the tall narrow pointed windows (whence it is often called the Lancet style), used singly or in groups, the pointed arch, clustered shaft, and ribbed groined vault, together with certain

characteristic decorative details, such as the exquisitely carved foliated capitals with round abaci, and the fine crowded moldings of the pier arches. Structurally the buildings of this period show an imperfect appropriation of the Gothic principle of isolated supports and concentrated thrusts. The wall was still the basis of design, the masonry massive, the windows relatively small, and the interior division into bays not strongly expressed. Towards the end of the period, however, the windows were increased in size, the walls made thinner, the piers lighter; geometric bar tracery (see TRACERY) began to replace the plate tracery which had early come into use in place of mere groupings of lancet windows; and the Gothic principle of vaulting on a framework of ribs was carried farther than in France by the multiplication of the ribs (tiercerons). The chapterhouses of Lincoln, Salisbury, Westminster Abbey, and Wells, of the second half of the thirteenth century, and the cloisters of Salisbury, are completely Gothic in construction as well as style. But, owing in part to the lowness of the vaulting, in part to English conservatism, the flying arch and buttress were never conspicuous in this period, the resistance to thrust being effected by arches under the side-aisle roofs in most cases.

The earliest example of the style is the choir of Canterbury (1175-84), followed by the choir, transepts, and later the nave of Lincoln (1192-1250). Lincoln is almost purely English in every feature except the six-part vault of the east transept, which is French in design, as is the Canterbury choir. The nave of Wells (1190-1225) is Gothic in details, but Norman in conception. The most complete exemplar of the style is Salisbury Cathedral (1220-58). Westminster Abbey was begun in 1245, but the nave was not completed till the fifteenth century; it shows a French Gothic conception carried out with English details. Other examples are the choirs of Worcester, Chester, and Gloucester cathedrals, the transepts of York, parts of the choir of Ely and Winchester, and the "Nine Altars" of Durham. Consult: Rickman, *An Attempt to Discriminate the Styles of English Architecture* (London, 1849); Moore, *Development of Gothic Architecture* (New York, 1899) and *Medieval Church Architecture in England* (ib., 1912); Prior, *History of Gothic Architecture in England* (London, 1900); Bond, *Gothic Architecture in England* (ib., 1907) and *An Introduction to English Church Architecture* (ib., 1913).

EARLY ENGLISH TEXT SOCIETY. A society founded by F. J. Furnivall (q.v.) in 1864 for the publication of Old and Middle English manuscripts. It has issued every year original-series texts (devoted to first editions of manuscripts), and since 1867 extra-series texts (mainly reprints of old books printed by Caxton and other early publishers). The society has as members some of the best English scholars in England, the United States, and Germany. Its numbers, numbering more than 200, are indispensable to the student of early English literature.

EARMARK. A method of identification of cattle in the West used in addition to branding (q.v.). It consisted in a slitting, cropping, or notching of one or both ears and was usually made when the calf was being branded. Each cattleman had his distinctive earmark as well

as his brand, and the great value of the former lay in the fact that when the half-wild range cattle saw a man they invariably turned and faced him so that the projecting ears showed the earmark plainly. Earmarks were too easily altered by the cattle thief to be a proof of ownership without a brand, but, as they could be read at a much greater distance than the latter, they saved the cowboy many hours of riding. The earmark was usually described as "right top-bit, left full-crop," or "right slit, left half-crop and slit," etc.

EARN, ȕrn. A river and loch in the south of Perthshire, Scotland, in the beautiful valley of Strathearn (Map: Scotland, E 3). The loch is 6½ miles long, 1 mile wide, and 287 feet deep, and bordered by rugged hills. The river Earn flows east from the loch for 49 miles, past Comrie, Crieff, and Bridge of Earn (a popular summer resort), into the estuary of the Tay, 7 miles southeast of Perth. The river is navigable for small vessels as far as the Bridge of Earn. Along the river, near Abernethy, under a thick bed of clay, is a peat bed 2 or 3 feet thick, supposed to be a continuation of the submarine forest at Flisk.

EARNEST (from Welsh *ernes*, *ern*, pledge). A coin or other article, usually of trifling value, given by a purchaser to his vendor "to bind the bargain" of sale. The practice is one of great antiquity and belongs to the order of ceremonial transactions so common in all early legal systems, the validity of which turns on the due observance of a prescribed form of proceeding rather than upon an inquiry as to the real intention of the parties thereto. The giving of earnest is, therefore, not at all the same thing as part payment on the one side or part delivery on the other, with which it is often confused; and, in the case of earnest proper, no allowance is made for the value of the coin or token given upon the settlement of the transaction. Notwithstanding its quaint and antiquated character, the use of earnest is still recognized in the law of England and the United States as the equivalent of the consideration essential to the validity of a contract. The Statute of Frauds (29 Car. II, c. 3), as now existing in England and reenacted in the United States, not only recognizes the legal validity of the act of giving earnest, but makes the distinction between it and the act of making part payment.

EARRING. An ornament suspended from the lobe of the ear, which may or may not be pierced for the purpose. The practice of wearing earrings is of the highest antiquity. In the ancient world there was a marked difference between the Asiatic races, among whom earrings were worn by both sexes, and the Greeks and Romans, whose women alone used them. Earrings have always formed an important branch of artistic jewelry.

Egypt and Assyria. Among the Egyptians the earliest rings were extremely simple—either single hoops of gold, from 1½ to 3 inches in diameter, or several hoops (as many as six) soldered together. Royal earrings were sometimes in the shape of an asp set with precious stones. Later forms, copied from Asiatic and Hellenic models, show the ring ending in the form of a dragon or antelope's head; others are pendants in the form of a vase, with incrustated work or with heads of divinities in relief. But the earliest homes of the really artistic earring were Babylonia, and later Assyria, where it

was a sign of rank among the men. Kings, nobles, and soldiers, as well as gods and genii, wore earrings; the Assyrian bas-reliefs show the variety of their design. Their general form is that of a pendant, sometimes a long drop or cone attached to a heavy ring or crescent, and often, especially under the later kings, that of a cross or groups of balls, lion-headed or bull-headed genii, the symbols of Assur and other gods. The materials were gold and silver; pearls were sometimes added. Molds for earrings have been found among the Assyrian palaces at Koyunjik and Nimrud. While the size and decoration were always kept within bounds by the Assyrian jewelers, greater extravagance was aimed at by the Persians as well as by the goldsmiths of Phœnicia, Syria, and the Hellenic peoples of the Ægean. The statues from Cyprus, the tombs of Syria and of Sidon, show Assyrian influence enriched.

Greek and Etruscan. The Mycænæan and Homeric women used rich earrings. At Mycenæ and Hissarlik (Troy) the excavations of Dr. Schliemann included many early gold earrings of different shapes—the bell-and-chain pendant, the fringe pendant, the gondola, the claw-shaped, the circular plaque, and several more. In the *Iliad* (xiv, 182–183), Hera wears earrings ending in three drops. The true character of this period may be inferred from the examples found at Camiros in Rhodes; they are long pendants, with rectangular plaques, diversified by zones of nude figurines and heads joined by little circular rosettes of filigree work. These earrings fall into two main classes: (1) those that hang just in front of the lobe of the ear and serve to conceal it; (2) those that hang below the ear and aim to continue its lines, not to conceal them.

The pre-Hellenic and Hellenic earrings, forming an elaborate network of design in several stories, appear to have influenced the Etruscans more than the later Greeks; for the Greek earrings of the sixth and fifth centuries B.C. are extremely simple and small, and it is not until the fourth, and especially the third, century B.C. that the richer Hellenistic art returned to the more elaborate style of design. The Etruscan tombs furnish the largest number of examples for the early part, those of southern Russia for the later part, of this period. The museums containing the largest number are: the Gregoriana at the Vatican, the Campana collection at the Louvre, the Castellani collection at the British Museum, the Metropolitan Museum in New York—all of which have been gathered from the contents of Etruscan tombs—and the Hermitage collection at St. Petersburg, with the superb series from southern Russia, especially from Kerch. They must be classified into two series: votive earrings, of very thin gold and frail workmanship, made only for burying with the deceased; and earrings for use, of heavier workmanship. The Etruscan tombs contain earrings that are both Italian and Greek—it is not easy to distinguish them. They form the most numerous and continuous series of ancient times, giving the styles during about 600 years. The material is gold, embossed, with filigree and granulated work, of the famous technique which modern jewelers, headed by the great antiquarian artist, Castellani, have tried to revivify. The main Etruscan designs are the following: the hand-bag shape, formed of a plaque with handle, dec-

orated with spirals, granulations, balls or figured designs, linear or in relief—an early form, seventh century; the gondola shape, with a bunch of three drops decorated with little groups of pearls, popular in the sixth century; the ear plaque, a disk usually circular, but sometimes oval, square, or oblong, with borders and zones of ornamental designs in relief and filigree and with its pendent bunch of drops, as in the previous kind used in the fifth and fourth centuries; the ring with pendant, usually large and sometimes with a series of single drops, a style common in the latest tombs of the fourth and third centuries. Some unusual specimens do not belong to any of these types. An exquisite pair of late workmanship from Bolsena, now in the Louvre, has for its central piece a vase, surmounted by Apollo as sun god, drawn by four horses in a chariot, and accompanied by winged Victories; its artistic beauties are to be seen only under a magnifier. Another beautiful pair from southern Russia, among the many at St. Petersburg, has as centre a circular plaque with a Nereid on a Triton in relief. Such elaborate works have a profusion of hanging figurines, flowers, fruits, birds, vases, chain nets, and their goldwork is often enhanced by colored enamels. The late-Greek artists in the service of the kings of the region of the Bosphorus, whose works abound in southern Russia, appear to have excelled all others. Both Greek and Roman statues exist with the lobes of their ears bored for earrings—as in the Medici Venus.

Roman. The Romans naturally inherited the taste from the Etruscans and later borrowed forms from late-Greek art. Pliny says (xi, 50) that there was no part of dress on which greater expense was lavished; and Seneca mentions one worth a patrimony, consisting of four pearls above and below a central precious stone. Roman artists popularized for the first time the use of precious stones in earrings. It was characteristic that they valued them, not as the Greeks had, for beauty or workmanship, but for the value of the material. Roman earrings were therefore much less artistic, and jewels, especially pearls and emeralds, replaced gold, almost entirely excluding the old methods and designs. This is especially noticeable during the later Empire. It is interesting to note that the Roman poets and writers speak of distinguishing an Oriental man by his use of the earring.

Byzantine and Barbaric. Proof that it still remained the custom in the East for the men to wear earrings even later is given by several Byzantine works of art, such as the mosaics representing Justinian and Theodora at Ravenna, and ivories of later Byzantine rulers, in which the emperors as well as the empresses wear earrings. The type of loop earrings and those with filigree work were, however, perpetuated even through the early Christian period, with ornaments of spirals and pellets, bands, circles, and even birds, found in Egyptian, Italian, and other tombs. The barbarous tribes of the North, who destroyed Roman civilization, varied in their use of the earring. The Goths, coming from farther east, were partial to them, with heavy gold and enamel designs; and in this they were somewhat rudely imitated by the Lombards. The Merovingian Franks affected a simple ring, with one or more stones set in the centre. But the Anglo-Saxons hardly used any. Many, however, are found in the early graves of Belgium,

France, Rhenish and Bavarian Germany, and especially Hungary, although none approach the beauty of classic or Etruscan design. Cloisonné enamel was a novelty in technique, introduced by these northern jewelers.

India. It is an interesting fact that late-Greek designs appear to have been introduced in Indian jewelry—in Cashmere and the Punjab, the style with gems and enamels; in Tibet, that with heavy gold forms; in Orissa and in other northern India, filigree and granular work. Indian earrings are the most gorgeous and artistic perpetuation in recent times of the ancient styles. At the same time the ancient designs of Assyria and Phœnicia are in part perpetuated among the modern Arab and Syrian tribes.

The Renaissance. The Middle Ages in Europe abandoned the earring in the circle of high life, the custom being perpetuated only by the peasantry. The innumerable works of art reproducing the costume of the period between the fourteenth and fifteenth centuries show hardly a single earring. The change of taste came during the Renaissance, especially on the approach of the sixteenth century. The Italian jewelers furnished models for nearly all Europe, and the technique reverted to goldwork with frequent use of enameling and precious stones. The pendent type was universally employed, of many shapes, based on the circle, the cross, the heart, the drop. There was every variety of style, from heavy embossed work in solid metal, often with figures in high relief, to the even more favorite form of lacelike openwork in the rather regular geometric patterns of Renaissance design, with occasional free use of foliage and flowers, though never so realistic as in ancient jewelry. Portuguese, Spanish, German, French, and Italian work of the sixteenth and early seventeenth centuries, while based on Italian originals, developed national characteristics; and this style, sinking into the middle and peasant classes, has been perpetuated by them, alongside of even more antique patterns, up to the present time. It was among the jewelry of the peasants of modern Tuscany that Castellani found the lost secrets of the Etruscan jewelers. The so-called peasant jewelry of Europe, as first shown by the Paris Exhibition of 1867 (now in South Kensington Museum), presents the only modern characteristic European work comparable to that of modern India in regard to earrings as well as other branches of the art. In many primitive parts of Europe—the Basque Provinces, Brittany, Normandy, and southern Italy—the men as well as the women wear earrings, but usually in the form of simple rings. Between 1876 and 1890 the earring began to disappear in Western Europe, England, and America. From 1885 to 1905 the earring was scarcely seen in the upper classes of society, and the custom of piercing the lobe of the ear fell into disuse. In the opening decade of the twentieth century the earring began to return, long earrings, 1914, being worn in England, short in France and America, but without piercing the ear. EARS-TO-EAR BIBLE. See BIBLE, CURIOUS EDITIONS OF.

EARTH, FIGURE OF. See GEODESY.

EARTH, THE (AS. *eorpe*, Icel. *jörp*, Goth. *airpa*, Teut. *Hertha*, OHG. *erde*, Ger. *Erde*, earth; connected with Gk. *ἐρα-ζε*, *era-ze*, on the ground, and possibly with Lat. *arvum*, field, *ararc*, Gk. *ἀρουρ*, *aroun*, OChurch Slav. *orati*, Ir. *araim*, Goth. *arjan*, Icel. *erja*, OHG. *erian*, dialectic Ger. *aren*, *eren*, AS. *erian*, archaic Eng. *ear*, to plow). The planet on which we live, the third in order of distance from the sun, and the largest within the orbit of Jupiter.

The Form and the Magnitude of the Earth. To a spectator so placed as to have an unobstructed view in all directions, the earth appears a circular plain on whose circumference the vault of heaven seems to rest. In ancient times even philosophers looked upon the earth as a flat disk swimming upon the water. But many appearances were soon observed to be at variance with this idea, and even in antiquity the curved form of the earth began to be suspected. It is only by assuming the earth to be curved that we can explain how our circle of vision becomes wider as our position is more elevated, and how the tops of towers, mountains, masts of ships, and the like, come first into view as we approach. There are many other proofs that the earth is a globe. Thus, as we advance from the poles towards the equator, new stars, formerly invisible, come gradually into view; the shadow of the earth upon the moon during an eclipse is always round; the same momentary appearance in the heavens is seen at different hours of the day in different places on the earth's surface; and lastly, since 1519 the earth has been circumnavigated innumerable times. It is not, however, strictly true that the earth is a sphere; it is slightly flattened or compressed at two opposite points—the poles—as has been proved by actual measurement of degrees of latitude (q.v.) and by observations of the pendulum. It is found that a degree of a meridian is not everywhere of the same linear length (see DEGREE OF LATITUDE), as would be the case if the earth were a perfect sphere, but increases from the equator to the poles, from which it is rightly inferred that the earth is flattened there. A pendulum, again, of a given length is found to move faster when carried towards the poles and more slowly when carried towards the equator; which shows that the force of gravity is less at the equator than at the poles, or, in other words, that the centre is more distant at the former than at the latter. The diminished force of gravity at the equator has, it is true, another cause—viz., the centrifugal force arising from the rotation of the earth, which acts counter to gravitation, and is necessarily greatest at the equator, where the linear velocity of rotation is greatest, and gradually lessens as we move northward or southward, till at the poles it is nothing. But the diminution of the force of gravity at the equator, arising from the centrifugal force, amounts to only $\frac{1}{289}$ of the whole force; while the diminution indicated by the pendulum is $\frac{1}{178}$. The difference, or $\frac{1}{178}$ nearly, remains assignable to the greater distance of the surface from the centre at the equator than at the poles. From the most accurate measurements of degrees that have been made, the flattening or ellipticity of the earth has been determined at $\frac{1}{311}$ nearly; or the equatorial radius is

to the polar as 300 to 299. These measurements of degrees determine not only the shape, but also the size of the earth. It is thus found that the equatorial semidiameter amounts to 3963 miles, while the polar semidiameter is 3950 miles.

The Mass and Density of the Earth. There are several methods of weighing the earth: I. The first method is by observing how much the attraction of a mountain deflects a plummet from a vertical line. This being observed, if we can ascertain the actual weight of the mountain, we can calculate that of the earth. This method was first used by Bouguer, who in 1740 attempted to measure the deviation in the plumb line produced by the horizontal attraction of Chimborazo, a mountain in the Peruvian Andes nearly 20,000 feet high. Although the experiment was not very satisfactory, still it showed that a deviation was actually produced, and about 35 years later the method was employed with greater success by Maskelyne. From experiments performed in 1774-76 at Schiehallion, in Perthshire, Scotland, he calculated the earth's mean density to be five times that of water. Schiehallion is a large mountain, lying east and west, steep on both its northern and southern faces, and of such a shape that it is possible to calculate both the mass, and the attraction which it exerts, with a considerable degree of exactness. The observed deflection of the plummet in these experiments was about six seconds. The same method was used in 1855 by Colonel James, director of the Ordnance Survey, Arthur's Seat, near Edinburgh, being used as the attracting mountain. The value which he obtained for the mean density of the earth was 5.32. II. A second method, which was also first used by Bouguer in Peru, is by observing the times of swing of a pendulum at the earth's surface and also at the summit of a high mountain. It is then possible to determine the attraction of the earth as compared with that of the mountain, and, as the latter can be calculated when the shape of the mountain and the density of its component rocks are known, the attraction of the earth is easily found. Experiments of this kind were performed in 1821 by Carlini on Mont Cenis, in 1865 by Pechman at Gerold in the Alps, in 1880 by Mendenhall at the summit of Fujiyama in Japan, and in 1892 by Preston on Mauna Kea in Hawaii. A modification of this method was introduced by Airy. Instead of swinging the pendulum at the top of a mountain, he observed its time of swing at the bottom of a deep mine. In this way the attraction of the whole earth was compared with that of the spherical shell of the earth's crust whose inner surface passed through the bottom of the mine. His first attempt to carry out the experiment at the Dolcoath copper mine in Cornwall, England, proved abortive, but in 1854 he performed it at the Harton Pit, near Sunderland, and obtained for the mean density of the earth a value of about 6.5. Similar experiments were made in 1883 and 1885 by Von Sterneck in silver mines in Bohemia and Saxony. In the methods just described, however, there must always be uncertainty, however accurate the observations, in regard to the mass or weight of the mountain or, in the case of the mine experiments, of the shell of the earth's crust. III. The method known as Cavendish's is much freer from liability to error. This method was first employed in 1798 by Henry Cavendish on the sug-

gestion of Michel and has since been repeated with various modifications by Reich, Baily, Cornu and Baille, Wilsing, Boys, Braun, and Eötvös. In the apparatus used by Baily, a fine rod carrying two small balls at its extremities is suspended by a wire and the position of the balls is carefully observed by the aid of a telescope. Large balls of lead placed on a turning frame, the centre of which is in the prolongation of the suspending wire, are then brought near the suspended balls in such a way that they can affect them only by the force of their attraction. On the large balls being so placed, the small ones move towards them through a small space, which is carefully measured. The position of the large balls is then reversed—i.e., they are placed at the same distance from the centre on the other side of the wire, and the change of the position of the small balls is again observed. Many observations are made, till the exact amount of the deviation of the small balls is ascertained beyond doubt. Then by calculation the amount of attraction of the large balls to produce this deviation is easily obtained. Having reached this, the next question is, What would their attraction be if they were as large as the earth? This is easily answered; and hence, as we know the attractive force of the earth, we can at once compare its mean density with that of lead. Baily's experiments lead to the result that the earth's mean density is 5.67 times that of water. In most of the experiments made by Cavendish's method the attracted masses used were of considerable size. By employing a quartz fibre as the torsion wire, Boys made it possible to use as the attracted masses gold balls only $\frac{1}{8}$ of an inch in diameter, while the attracting masses, which were of lead, were only $\frac{1}{16}$ inches in diameter. IV. A fourth method, which has been successfully employed in various forms by Von Jolly, Poynting, and Richarz and Krigar-Menzel, consists in using an ordinary chemical balance and measuring the change of weight when a large attracting body of known shape and mass is placed above or below the scale pan which carries the mass to be weighed. In the experiments of Richarz and Krigar-Menzel the attracting body was a rectangular mass of lead of nearly 100 tons.

The values of the earth's mean density obtained by the various experimenters referred to in the foregoing account are summarized in the table given below:

OBSERVER	Date	Method	Mean density
Maskelyne	1775	I	5.00
Cavendish	1798	III	5.45
Carlini	1821	II	4.84
Baily	1843	III	5.67
Reich	1852	III	5.58
Airy	1854	II	6.57
James	1855	I	5.32
Pechman	1865	II	6.13
Cornu and Baille	1878	III	5.50
Mendenhall	1880	II	5.77
Von Jolly	1881	IV	5.69
Sterneck	1883	II	4.77
Sterneck	1885	II	6.77
Wilsing	1889	III	5.56
Poynting	1891	IV	5.49
Preston	1892	II	5.13
Boys	1895	III	5.53
Braun	1896	III	5.53
Eötvös	1896	III	5.53
Richarz and Krigar-Menzel	1898	IV	5.51
Burgess	1902	III	5.55

It will be observed that the values most recently obtained are in substantial agreement, and it is therefore probable that the true value of the earth's mean density is very nearly 5.53. The density of the earth being known, its mass or weight is easily calculated and made a unit for measuring that of the other bodies in the solar system. It is estimated that the mass of the earth is 6000 billions of billions of tons.

The Motions of the Earth. The earth, as a member of the solar system, moves along with the other planets round the sun from west to east. This journey round the sun is performed in about $365\frac{1}{4}$ days, which we call a year (solar year). The earth's path, or orbit, is not a circle, but an ellipse of small eccentricity, in one of whose foci is the sun. It follows that the earth is not equally distant from the sun at all times of the year; it is nearest, or in perihelion, at the beginning of the year, or when the Northern Hemisphere has winter; and at its greatest distance, or aphelion, about the middle of the year, or during the summer of the Northern Hemisphere. The difference of distance, however, is too small to exercise any perceptible influence on the heat derived from the sun, and the variation of the seasons has a quite different cause. The least distance of the sun from the earth is over 91,000,000 miles, and the greatest over 94,000,000; the mean distance is commonly stated at 92,900,000 miles. (See PARALLAX, SOLAR.) If the mean distance be taken as unity, then the greatest and the least are respectively represented by 1.01677 and 0.98323. It follows that the earth yearly describes a path of upward of 560,000,000 miles, so that its velocity in its orbit is about 19 miles a second.

Besides its annual motion round the sun, the earth has a daily motion or rotation on its axis, which is performed from west to east and occupies exactly 23 hours, 56 minutes, 4.09 seconds of ordinary mean solar time. On this motion depend the rising and setting of the sun, or the changes of day and night. The relative lengths of day and night depend upon the angle formed by the earth's axis with the plane of its orbit. If the axis were perpendicular to the plane of the orbit, day and night would be equal during the whole year over all the earth, and there would be no change of seasons; but the axis makes with the orbit an angle of 23.5° , and the consequence of this is all the variety of seasons and of climates that we find on the earth's surface, for it is only for a small strip (theoretically for a mere line) lying under the equator that the days and nights are equal all the year; at all other places this equality only occurs on the two days in each year when the sun seems to pass through the celestial equator—i.e., about March 21 and September 23. From March 21 the sun departs from the equator towards the north, till, about June 21, he has reached a northern declination of 23.5° , when he again approaches the equator, which he reaches about September 23. He then advances southward and about December 21 has reached a southern declination of 23.5° , when he turns once more towards the equator, at which he arrives March 21. The 21st of June is the longest day in the Northern Hemisphere and the shortest in the Southern; with the 21st of December it is the reverse. The linear velocity of axial rotation at the earth's surface evidently increases gradually from the poles to the equator, where it

is about 24,840 miles a day, or about 1440 feet in a second. A direct proof of the rotation of the earth is furnished by experiments with the pendulum, which, as we have already pointed out, show a decrease of the force of gravity from the poles towards the equator; and though a part of this decrease is owing to the want of perfect sphericity, a part also arises from the

direct proof of rotation may be drawn from the observation that bodies dropped from a considerable height deviate towards the east from the vertical line. The analogy of our earth to the other planets may be also adduced as an argument, since their rotation, with the exception of the smallest and the most distant, is distinctly discernible. Finally, an additional proof of the earth's rotation was given in 1851 by Foucault's experiment with the pendulum. The principle of the experiment is this—that a pendulum once set in motion, and swinging freely, continues to swing in the same plane, while at any place on the earth the plane of the meridian continues to change its position relative to this fixed plane. This experiment, being tried, verified the expected rotation most satisfactorily.

If the turning of the earth on its axis is once admitted to be the cause of the apparent daily motion of the heavens, it is an easy step to consider the annual motion of the sun through the constellations of the zodiac as also apparent and arising from that revolution of the earth about the sun which we have already mentioned. If we consider that the mass of the sun is about 332,000 times greater than that of the earth, and that by the laws of mechanics two bodies that revolve round each other must revolve about their common centre of gravity, the idea of the sun revolving about the earth is seen to be simply impossible. The common centre of gravity of the two bodies, being distant from the centre of each inversely as their respective masses, is calculated to be far within the body of the sun, which has a diameter of 866,400 miles. But it is easy to see how the apparent motion of the sun on the ecliptic naturally arises from a motion of the earth about the sun. The motions of the planets, also, that appear so complicated and irregular as seen by us, can be satisfactorily explained only by assuming that they, too, revolve round the sun in the same direction as the earth. See the articles PRECESSION and NUTATION for an account of a small periodic motion of the earth's axis and its effects.

The Earth's Temperature. The phenomena of heat on the earth's surface are described under CLIMATE; METEOROLOGY; and other heads. As we go below the surface, we reach a depth beyond which the interior of the earth seems to have no sympathy with the external causes of heat or cold, and its heat appears to be its own and to increase according to a fixed law the deeper we descend. The average rate of observed increase is 1° F. for a descent of between 40 and 50 feet. The distribution of the land and water surfaces, with their area, is discussed in the article GEOGRAPHY (q.v.). For the physical features of the earth, see GEOLOGY.

EARTH CHESTNUT. See EARTHNUT.

EARTH CLOSET. See SEWAGE.

EARTH EATING. The practice of eating clay. See GEOPHAGY.

EARTHENWARE. See POTTERY.

EARTH HOG, or EARTH PIG. A name for the aard-vark (q.v.).

EARTH LODGE. The specific name for the type of house formerly used by the Mandan, Hidatsa, Arikara, Pawnee, Ponca, Omaha, and perhaps other tribes of the Mississippi valley. A circular pointed framework of logs was set up, covered with fine brush or grass, and the whole given a heavy coating of earth. The lodge was in no sense an underground house, though the surface soil within was removed to the depth of 2 or 3 feet to secure a firm earth floor. (See INDIANS, AMERICAN.) True subterranean houses were used by the natives of Alaska and parts of British Columbia, Washington, and California. Jochelson has traced a possible historical connection between these American examples and the subterranean houses of northern Asia and ancient Europe. Consult *Proceedings of the International Congress of Americanists* (Quebec, 1906); also Wissler, in the *Proceedings of the Vienna meeting* (1909).

EARTHLY PARADISE, THE. A series of narrative poems by William Morris, modeled on Chaucer's *Canterbury Tales* and published in 1868-71. The separate poems are mythological stories told by Norwegian voyagers in search of an earthly paradise.

EARTHNUT. A popular name for the tubers of certain umbelliferous plants, particularly *Carum bulbocastanum* and *Conopodium fleuosum*, which are common in most parts of Europe. Names of the same signification are given to them in a number of European languages. Pignut is another common English name, because pigs are very fond of them. They are also called earth chestnut, from their resemblance in taste and qualities to chestnuts. They are wholesome and nutritious and form an article of trade in Sweden and have sometimes been recommended as worthy of more attention than they have yet received. *Carum ferulaefolium* likewise affords tubers, which are used as food in Greece. The somewhat similar tubers of other umbelliferous plants, as *Enanthe pimpinelloides* and *Cherophyllum tuberosum*, are sometimes also used for food. The name "earthnut" is sometimes extended to other small tuberous roots or subterranean fruits of similar quality, although produced by botanically unrelated plants, as *Aptis tuberosa* (used as food by Indians on the North Atlantic coast), *Lathy-*

rus tuberosus, *Cyperus rotundus*, *Arachis hypogaea*, etc.

EARTHQUAKE. A tremor or shaking of the ground produced by natural subterranean concussion, from tectonic or volcanic causes. The disturbance is not necessarily violent or even sensible to ordinary means of observation, but can be detected by the delicate instruments which have been devised for recording the vibrations in their passage through the earth. The record of an earthquake thus obtained has a definite character and is readily distinguished from the motion set up by artificial causes, e.g., underground explosions, artillery fire, or the movement of heavy traffic on a city street. With the recent advances in the instrumental methods of investigation it has been found that earthquakes are much more common than had been supposed; in fact, they are of daily occurrence in some parts of the world, and the range of the vibrations set up by a heavy shock extends over the whole globe. The average seismic frequency is probably greatest in Japan, where records for a period of eight years showed a total of 8831 shocks, or an average of 3 a day. The larger number of earthquakes belong to the class of *microseisms* (unfelt disturbances); the destructively violent types, or *macroseisms*, are relatively rare, and then may be centred in remote localities or under the sea so as to attract little notice.

Succession of Phenomena. The phenomena manifested by a powerful earthquake within the zone of destruction vary considerably according to the position of the place of origin with regard to the focus of the disturbance, the relative intensity, and the nature of the ground at that place. Consequently the course of events may appear quite differently to observers stationed at different points within the zone. The first phase, however, is usually a slight trembling or a series of separate shocks that last a few seconds; then follows almost immediately a violent motion, which in some instances seems to consist of an actual rising and falling of the ground in waves that advance with great rapidity and in other cases involves more of a horizontal to-and-fro movement, or shakings of short amplitude but extremely rapid. The violent motion lasts only a fraction of a minute usually and subsides into smaller vibrations that gradually diminish to insensibility. An earthquake of this kind is almost always accompanied by sounds, which, also, are heard sometimes with moderate shocks. The sounds may precede or follow the main vibrations, and in some cases sound and shock appear to be simultaneous. The sounds are variously described as resembling the rumbling of thunder, the roar of heavy artillery, and the crashing of an immense mass of glass; no doubt they are frequently confused with the noise produced by falling objects, the crushing of timbers, etc., which is a very different matter than an accompaniment of the shock itself. The actual sound is a low pitched rumbling and is caused by the vibratory motion of the air in sympathy with the ground waves. It always appears to issue from the earth, but, contrary to popular belief, is not actually transmitted through the rocks.

The suddenness of a violent disturbance makes contemporaneous observation very difficult, while escape from its effects is almost impossible. The main shock is announced only by a brief period of minor tremblings and is over in a

minute or two after the first motion. Premonitory tremors may occur at intervals for several days or months previous to the earthquake, but in a country where slight shocks are frequent their real significance is not apparent even to the scientist. The time of safety has passed. The display of energy within the brief period is without parallel in any other manifestation of natural forces. The zone of destruction of a powerful disturbance extends over many thousand square miles, and within the narrower epicentral tract the havoc wrought upon life and property is beyond the power of realization for those unacquainted with disasters of the kind. The Messina earthquake of 1908 demolished the whole city, so that scarcely a building was left standing, and did extensive damage to the adjacent districts of Sicily and the mainland, involving a loss altogether of nearly 80,000 lives. Volcanic outbursts alone are attended by similar scenes of violence and horror, yet they are incapable of accomplishing such widespread destruction.

Earthquake Motion. Earthquakes travel through the ground as elastic waves. The rocks which constitute the outer zone of the earth, or the so-called crust, as well as the underlying layers, which are of uncertain nature, behave within certain limits like elastic media, transmitting vibrations in a manner similar to the air when set in motion by sound. Any jar or disturbance of equilibrium within the rock mass produces a series of waves of alternate tension and compression which advance by communicating the motion from particle to particle. The vibrations may take place in the same direction as the disturbance is transmitted and are then called longitudinal waves, or they may occur at right angles to the direction of travel, when they are known as transverse waves. Both kinds are concerned in the propagation of an earthquake. The waves are of small amplitude—a mere fraction of an inch in the unfelt tremors, but possibly an inch or two in the very violent shocks. No actual measurements in the latter case are possible, since no instruments could withstand the terrific shaking. The periods, or time consumed in a single vibration, range from two or three seconds to about half a minute, as measured at a distance from the focus.

In the instrumental record of earthquakes at points without the danger zone it has been found that the wave motion is divisible into different phases, or parts, called the preliminary, the main, and the final phases. The preliminary phase consists of minor tremors, scarcely perceptible at first, but developing into well-marked vibrations of fairly constant period. Some records show two classes of these waves, which are then called the first and the second preliminaries. The main phase develops very rapidly out of the preliminary vibrations into waves of much greater amplitude and longer periods; it corresponds to the destructive part of the disturbance close to the source. The large swings after an interval gradually diminish, and then enters the final phase of small, interrupted tremors which represent probably the refracted and reflected parts of the earlier movements. All of the waves start approximately at the same time from the earthquake centre, but the small tremors of the preliminary phase outravel the longer waves of the principal phase.

From calculations of the times of arrival reported by different stations for the California earthquake of 1906, Reid found that the first preliminaries traveled at a velocity of from 7.2 kilometers a second near the origin to 11.7 kilometers a second at a distance of 110° of the earth's arc; the second preliminaries had a velocity ranging from 4.8 kilometers to 6.4 kilometers; and the main vibrations a constant velocity of 3.75 kilometers a second. There is, thus, not only a variation of relative speeds, but the first and second preliminaries, carried forward perhaps as longitudinal waves, increase their apparent velocity with increasing distance from the source. This relation is regarded as indicating that the waves of the first phase pass through the earth, not perhaps by the shortest path along an arc, but in directions corresponding to the maximum elasticity of the medium. The important practical feature of this variation is that it permits accurate deduction from an instrumental record as to the distance traveled by the disturbance from its source. The data supplied by a series of stations also afford the information necessary to deduce the direction of wave propagation, so that from the known factors of distance and direction the disturbance may be traced to its origin.

The structure and nature of the rocks have effect upon the transmission of the wave motion, causing refractions and variations in speed and intensity, which would not be possible if the earth were a uniform solid. Certain localized areas within the zone of destruction may be much less affected than the rest of the area; also shocks are sometimes felt in mines that escape observation at the surface and vice versa. The great damage to structures results when they are placed on alluvial or made ground; it appears that loose materials accentuate the wave motion, or rather perhaps transform the tremors into slow undulations of greater amplitude, at the same time that they may be subjected to a propulsive action.

Depth of Source. The source from which the waves emanate is known as the focus, or centre, and the place above the focus on the surface, as the epicentre. The terms rather imply that a disturbance begins at a point or within a very limited zone, but such is not the case—at least for all tectonic earthquakes, the most common and damaging kind. The focus involves a mass of three dimensions, and the epicentre may be an area of several hundred square miles. The determination of the depth of the focus for different shocks has been attempted by Mallet, Dutton, and others, but without any very conclusive results. The method used by Mallet rests upon observations of the effects produced in walls and buildings, on the assumption that the cracks develop mostly at right angles to the direction of wave emergence; it is not very reliable, owing to the numerous refractions and reflections the waves undergo before emerging at the surface. The general consensus of opinion, however, is that the focus is relatively shallow, probably not more than 10 or 20 miles from the surface in most shocks.

Relative Magnitude. The violence of an earthquake depends directly upon the violence of the motion, also upon the depth of focus. No practical means have been found to measure the absolute degree of intensity or the energy developed by a shock. A scale of relative intensities, known as the Rossi-Forrel scale, is much used by seis-

mologists and is based partly on the personal sensations of individuals within the disturbed area and in part upon the external effects. The scale is arranged in ascending order of intensity, as follows: 1. Unfelt, only recorded by instruments. 2. Very feeble. 3. Feeble. 4. Light, felt by persons in motion. 5. Moderate, felt by every one. 6. Fairly strong, sleepers awakened, clocks stopped. 7. Strong, general panic. 8. Very strong, chimneys fall. 9. Extremely strong, partial or total destruction of buildings. 10. Disastrous, fissures opened, ruin. Around the epicentral tract may be drawn curves which will indicate the relative intensity of the shock within the places thus joined; such curves are called *isoseisms*. Similarly, *coseisms* are curves about the epicentre that connect places having the same times of arrival for any particular phase.

The damage inflicted by an earthquake is not necessarily proportional to its magnitude or intensity, since much depends upon how thickly the epicentral area is populated. The California shock of April 18, 1906, was not extraordinarily heavy compared with some other examples, although its destructive effects extended over a tract 350 miles long and 70 miles wide, disturbed an area of about 175,000 square miles, and involved tremendous financial losses. Most of the damage in San Francisco itself was incident to the fire, which on account of the disrupted water mains could not be brought under control. The Messina earthquake in 1908 had a limited epicentre within a populous district, where the buildings were ill adapted to withstand even moderate shakings. The loss of life from the disaster was officially reported as 77,283, far exceeding the number of deaths from any other earthquake of which there is authentic knowledge. Some of the most violent shocks have occurred in Japan and India. The Indian earthquake of 1897 was one of the heaviest in modern times, while that of 1905 in the vicinity of Kangra was reported to have been felt over an area of 1,625,000 square miles and was responsible for the death of 20,000 natives. The Charleston, S. C., shock of Aug. 31, 1886, the most violent of any recorded in the United States east of the Mississippi River, was perceptible over an area 800 miles wide and 1000 miles long. The Lisbon disturbance of 1755 appears to have been very intense, as it was also exceptionally destructive; a notable feature was the immense sea wave which swept the coast of Portugal and greatly aggravated the disaster, in which altogether 40,000 people were killed.

Origin. The question as to the causes of earthquakes has been a subject of speculation since very early times, but it is only with the adoption of scientific principles of investigation aided by instrumental experimentation during the last century or so that real progress has been made towards a solution. The question is difficult because the origin of disturbances lies within the hidden depths of the earth, and the exact conditions obtaining there can only be inferred from insecure data. It is now generally recognized, however, that two principal causes are concerned—the one tectonic and the other volcanic. The first refers to crustal dislocations, particularly the differential movements along fissures known as faults. From time to time stresses accumulate in the strata to a point where the elastic limit is exceeded, and then rupture and a slip result by which

equilibrium is once more restored. Such faults are very common, as may be observed from their surface indications in nearly all regions, and imply the ceaseless operation of enormous forces. The source of the stresses may possibly be the shrinking of the earth's interior away from the superstructure by reason of cooling, or the extrusion of igneous matter, or the escape of gases; the cause is not definitely known, but the immediate effects are very apparent. When fissures are once opened, they may serve repeatedly to relieve stresses. Thus, the last California earthquake is traceable to the recurrence of displacement along the San Andreas fault, previously marked out by other movements as a prominent topographic feature in the coast region from Benito County on the southeast to Humboldt County on the northwest. On the opposite sides of the fault plane the strata shifted horizontally a distance ranging from 7 or 8 feet up to 21 feet. In places also there was a vertical movement of from 1 to 3 feet. As the total length of the fault is estimated at 270 miles, the momentum of the mass involved must have been enormous. The tectonic earthquakes are the most numerous and probably account for nearly all disasters of seismic origin. Those of volcanic nature seldom seem to have far-reaching effects, though adding much to the terrifying aspects of the eruption which they accompany. They are traceable to concussions within the volcanic conduit, produced probably by the gases in their progress towards the surface; most of the imprisoned energy, of course, finds release in the eruption. The occasional paroxysmal outbursts of the kind exhibited by some of the Mediterranean volcanoes, or as exemplified by the explosive eruption of Krakatoa in 1883, when a large part of the island was blown into the air, generate fairly heavy shocks. A further cause of earthquakes, generally regarded, however, as not very important, is found in the jars produced by the collapse of caverns that have been hollowed out by underground waters in their circulation through soluble rock materials like limestone, gypsum, and rock salt.

Earthquake Zones. If shocks are mainly concomitants of crustal displacement as manifested in the fracture and faulting of rocks, it may be expected they will occur most frequently along lines of structural weakness. Accordingly lofty mountain regions, great inequalities between land surface and adjacent sea bottom, and the presence of fault scarps particularly, furnish some of the conditions necessary for the recognition of seismic areas. It is noteworthy, also, that most of our active volcanoes fall within such areas. The western coasts of North and South America, with their mountain ranges and precipitous shore lines, mark one of the main seismic zones, which joins on the north with another great zone that extends from southeastern Asia across the Japanese Archipelago, the Kurile Islands, and the Aleutian chain to the Alaskan mainland. Another has an east-west trend through the Mediterranean, the Azores, West Indies, Central America, Hawaii, East Indies, the Himalayan Range, Persia, and Asia Minor. The eastern coast of America and the western part of Europe are comparatively free from such disturbances.

Sea Waves and Other Phenomena. Many of the shocks propagated under the land have submarine origins. A part of the energy or motion in such cases is communicated to the

water, causing a compressional wave that is sometimes felt by ships at sea, though not often with damaging results. A great sea wave (erroneously called a tidal wave) may also be started, and if the epicentre is not too far removed from land the wave will dash upon the coast as a wall of water, sometimes 30 or 40 feet high, with irresistible force. The Messina earthquake, already mentioned, was precipitated by a disturbance in the near-by strait, and the following wave accounted for much destruction along the lower sea front. At San Alessio the water rose 38 feet, but at Messina itself it rose only about 10 feet; the wave reached Malta two hours after the earthquake. The motion in mountain regions not infrequently produces landslips, shaking down immense quantities of earth and rock from cliffs and insecure slopes into the valleys, where they may obstruct the streams so as to form temporary lakes. It has been noticed that glaciers after a disturbance will advance farther into the valleys, owing to the increased supply of snow at their sources contributed by avalanches. Within the epicentral tract the surface features may be modified by local elevations or subsidences of the ground, by the opening of chasms and fissures, by earth flows and the diversion of the drainage systems.

Seismology. The study of earthquakes has made notable advances during the last two or three decades and may be said now to rank as one of the coördinate branches of modern science, provided with its own instruments of observation, and followed by a band of workers that number representatives among all the principal countries. The systematic investigations undertaken in Japan, at first under the direction of J. Milne and later carried on by Omori and other Japanese seismologists, stimulated general interest, as they have also proved of great practical value in suggesting methods for mitigating the damage by shocks. At present work in this field is very active; stations equipped with instruments of record have been set up in many places in the United States, Europe, and elsewhere, some under government subsidy. Besides local societies and publications devoted to its interests, there is a central organization (Association Internationale de Sismologie), which issues from time to time valuable reports and is a leading influence in the extension and encouragement of research. The instrument for the registration of shocks is the seismograph (q.v.), which in its improved modern form is capable of detecting tremors from sources on opposite sides of the globe; by it the distance and direction of the larger disturbances may often be determined with great accuracy, and it detects many that otherwise would escape notice.

The principal objects of present inquiry are to discover the centres from which earthquakes most frequently emanate, the relative frequency with which they occur, and any possible relation that may exist between their frequency and other natural phenomena. The mapping of the seismic zones is a work of basic importance, necessary to forearm, if it does not supply the means for forewarning, against disastrous shocks. The ability to locate the origins of submarine disturbances, as shown by Milne, may be put to practical use in the laying out of routes for ocean cables. Frequent breakages of cables occur within zones subject to heavy

earthquakes, involving much loss from disuse and expense of repair. The analysis of the energy developed by the wave motion has a bearing obviously upon the design of buildings and the securing of proper foundations to withstand the strain. For foundations solid rock affords the greatest security, for reasons already explained; where it is impracticable to place buildings upon it some protection may be had by the excavation of a trench on the side from which the earthquakes usually come. Masonry construction and especially masonry arches, chimneys, and exposed ornamental work succumb most quickly; timber and steel structures, however, endure a heavy shaking.

Disasters. The Charleston, S. C., earthquake and the San Francisco shock, already mentioned, are the only heavy ones that have occurred within the United States in recent years and that have been responsible for widespread destruction. Neither involved a loss of life at all comparable with the losses incident to some that have occurred in other countries. One of the greatest catastrophes of modern times resulted from the Lisbon earthquake of 1755, when that city was overthrown and 40,000 people were killed; the tremors were felt in North Africa, Scandinavia, and as far away as the east coast of North America. Calabria and Messina were visited by an earthquake in 1783 that wrought almost as much devastation as the more recent Messina disturbance, and is said to have entailed a loss of 60,000 lives. Other disasters occurred at Aleppo, in 1822; at Naples, 1857; at Quito, 1859; in Peru, 1868; on the island of Ischia, 1883; and in Japan, 1891. The earthquake in northeast India (Assam) in 1897 was one of the severest that has recently been felt, but its centre fortunately was not in a heavily populated region. The Kangra disturbance of 1905 in the same country involved an area half as large as the United States. Valparaiso was partly destroyed by an earthquake in 1906, the same year as the San Francisco shock. Kingston, on the island of Jamaica, was devastated in 1907. The Messina disaster of 1908 exceeded all others in the completeness with which a great city was ruined and in loss of life. A heavy shock was reported in the Province of Luristan, Persia, in 1909; the city of Cartago, Costa Rica, was laid waste in 1910; and southern Mexico was visited by a damaging shock in 1911.

Bibliography. The Seismological Society of Japan, the International Investigating Committee (Japan), and the Association Internationale de Sismologie have issued important reports. As general treatises, may be mentioned: Milne, *Earthquakes and other Earth Movements* (6th ed., London, 1913); Dutton, *Earthquakes in the Light of the New Seismology* (New York, 1904); Montessus de Ballore, *Les tremblements de terre* (Paris, 1906) and *La science séismologique* (ib., 1907); Sieberg, *Handbuch der Erdbebenkunde* (Brunswick, 1904); Davison, *A Study of Recent Earthquakes* (London, 1905); Knott, *The Physics of Earthquake Phenomena* (Oxford, 1908); Reid, *Mechanics of the Earthquake* (Washington, 1910); Walker, *Modern Seismology* (New York, 1914). Monographic reports on separate occurrences include: Mallet, *The Great Neapolitan Earthquake of 1857* (London, 1862); Dutton, "The Charleston Earthquake of August 31, 1886," in *Ninth Annual Report United States Geological Survey* (Wash-

ington, 1889), Oldham, "Report on the Great Indian Earthquake of 12 June, 1897," in *Memours Geological Survey of India*, vol. xxix (Calcutta, 1889); Lawson, Reid, and Others, *The California Earthquake of April 18, 1906* (San Francisco, 1906); Miller, *Complete Story of the Great Earthquake of 1906* (Chicago, 1909); Mowbray, *Italy's Great Horror of Earthquake and Tidal Wave* (Philadelphia, 1909); Elliott, *Sicily in Shadow and in Sun* (Boston, 1910); Belknap, *American Housebuilding in Messina and Reggio* (New York, 1910). See GEOLOGY; SEISMOGRAPH.

EARTHS. A term formerly applied to the oxides of a number of elements. The alchemists applied the term in general to bodies that were insoluble or only slightly soluble in water and not changed by heat. With the establishment of modern chemistry by Lavoisier, the earths, which had been regarded as elements, became regarded as compounds. The term "alkaline earths" is still generally applied to the oxides of barium, calcium, and strontium, and sometimes to that of magnesium.

EARTHSHINE. The reflection from the moon of the light cast upon her by the earth, particularly noticeable on clear nights at the time of new moon, when sometimes the whole surface of the moon can be seen in ashy-colored light.

EARTH SNAKE. See SHIELDTAIL.

EARTHSTAR (translation of Neo-Lat. *Geaster*, from Gk. γῆ, *gê*, earth + ἀστήρ, *astēr*, star). A genus of puffballs which at the time of spore dispersal open in a starlike form. Before the period of spore dispersal the earthstar has a rounded or pear-shape form, seldom more than 2 inches in diameter. When the spores are ripe, the outer leathery layer of the skin, or periderm, splits radially from the central apex into a number of triangular segments, which spread so as to assume a starlike arrangement and then become strongly reflexed. In certain species, particularly in *Geaster*, this periderm is very sensitive to extreme dryness, with the result that the plant expands during moist periods and closes up during dry ones. Earthstars are found in nearly all parts of the world, some species being restricted to particular regions, while others are cosmopolitan. In America they are quite common in pastures and open woodlands. A puffball is merely the spore-bearing portion of a fungus, whose vegetative body (mycelium) branches extensively through the substratum. See BASIDIOMYCETES; FUNGI, and its accompanying Plate.

EARTHWOLF. A name for the aard-wolf (q.v.).

EARTHWORKS, MILITARY. A fortification, either temporary or permanent, constructed principally with earth. The principal classes of field or temporary fortifications or earthworks are *hasty intrenchments*, *deliberate intrenchments*, and *siege works*. There are many forms of earthworks, for which see FORTIFICATION; RE-DOUBT; TRENCH.

EARTHWORM. The popular name for worms of the family Lumbricidae, especially the common *Lumbricus terrestris* and *Allobophora foetida*. They belong to the oligochaetous section of the chætopod annelids and are widely distributed in temperate and tropical lands.

Habits. Like most other oligochaetes, earthworms are subterranean in their habits and appear above the surface only under unusual conditions, such as excessive rain, which floods

their underground burrows and forces them to the surface to avoid drowning. They also come to the surface to feed and to throw out their "castings," almost exclusively at night, although they have no eyes, by means of their detecting organs they avoid the light. Earthworms are often seen in great numbers upon sidewalks, steps, and paved streets after a wet night or a hard rain, and they are often reported to have actually "rained down." Such cases, however, are easily explained by the fact that the worms crawl about actively in their attempt to get out of the water and even climb up comparatively smooth surfaces, and, as the hard surface of the sidewalk or roadway prevents their reëntering the earth when daylight returns, they are all left exposed to view. Although naturally somewhat sluggish, these worms can burrow with considerable speed, especially in light soil. The burrowing is accomplished not only by forcing the bluntly pointed head between the particles of earth and forcing them apart, but also by actually cutting a hole with its mouth and swallowing much of the opposing material. In all their movements the short but stiff setæ, or bristles, along the sides of the body are of the greatest assistance. These setæ are arranged in pairs on each segment, two pairs on each side, so that every segment carries eight setæ, and they form two double rows along each side of the worm. Earthworms form the prey of many animals, from slugs upward, and are the principal food of moles, shrews, and the like. Their habit of going into the water, and the accidents of floods, cause many to fall a prey to fishes; and they are the commonest bait for still fishing, whence they are more commonly known in the United States as angleworms than by any other name.

Earthworms and Soil. The important part that earthworms play in the economy of nature was not generally recognized until attention was called to it by Charles Darwin. Most of our knowledge of the habits of these creatures is due to him. Earthworms are vegetable feeders exclusively. In their alimentary canal, where it is mixed with the vegetable food of the worm, and nearly all of it passes out with the castings, which are always voided on the surface. These castings are therefore a sort of natural compost, which the earthworms are continually depositing over the surface of the areas which they inhabit. They are thus not only constantly converting vegetable matter into more usable form, but are also so mixing it with inorganic matter as to make both of greater use. Such a process is called the formation of vegetable mold, and it is continually going on wherever the conditions are suitable. It is not of course confined to the agency of earthworms, though Mr. Darwin showed that they were one of the most important agents. The rate at which vegetable mold may be formed by these worms will vary of course with the character of the soil, the number of worms, and the abundance of food, but under favorable conditions it may be several inches in a century. Such soil is fertile not alone because of its composition, but because the movements of the worms keep it stirred up and well aerated. For further particulars in reference to the habits and usefulness of earthworms, consult Darwin, *The Formation of Vegetable Mould through the Action of Worms* (London, 1881).

Structure. Earthworms are generally of a uniform color, although there is a difference in shading between the upper and under surfaces and between different regions of the body. The color is usually flesh red, varying into dull pink on the one hand and dirty brown on the other. In size there is great diversity, some species reaching a length of only a few inches, while tropical species may be several feet in length. Large specimens of the common American species are rarely a foot long. In such specimens as many as 180 segments may be present, but 130 is about the average number. The muscular system of earthworms is well developed, and consists of an outer series of circular or transverse muscle fibres which girdle the body, and an inner series of longitudinal fibres which form five principal bands, and several smaller ones concerned with the movements of the setæ. The nervous system consists of a large ganglion above the œsophagus, often called the brain, and a ventral cord, which lies beneath the alimentary canal, and bears ganglia in every segment. This cord is connected with the brain by commis-

STRUCTURE OF AN EARTHWORM.

1. An entire worm, side view; 1, 1st segment and mouth; 15, 15th segment, showing opening of male genital ducts; 33, 33d segment and thickened clitellum. 2. Anterior portion of *Lumbricus terrestris*, laid open and enlarged; o, mouth; p, pharynx; g, gullet; m, œsophageal glands; c, proventriculus; s, gizzard; i, intestine; h, one of the "hearts" borne on the side of the dorsal vessel; t, seminal reservoirs; sp, spermatheca. (After Lankester.)

sures around the œsophagus. So far as known, there are no sense organs other than those of touch. The alimentary canal consists of a muscular pharynx, a slender œsophagus, a muscular gizzard and thin-walled crop, and a long, straight intestine, within which is a complex dorsal fold, to increase the digestive surface. The circulatory system is well developed and consists of a prominent dorsal blood vessel and no less than four ventral vessels, which run longitudinally in the body and are connected with each other by a regularly arranged series of transverse vessels, many of which form a network of capillaries in the muscles and in the wall of the intestine. In some of the anterior segments some of these transverse vessels are much larger than elsewhere and form very prominent arches, often called "hearts," of which there are usually five pairs. They are not functionally "hearts," however, or at least only in part, for most of the pumping is done by the dorsal trunk and general muscular movements. Excretion takes place through the very characteristic nephridia, of which there are a pair in each segment, one on each side of the intestine.

They consist of coiled tubes, having at one end a funnel-shaped opening into the body cavity, while the other end opens outside of the body. The funnel always opens into the segment just anterior to that in which the tube itself lies.

Reproduction. Earthworms are hermaphroditic—that is, both male and female reproductive organs occur in the same individual. But mutual cross-fertilization probably always takes place. The eggs are laid in capsules which are buried in the earth and serve to protect the young until they are well developed. These capsules are probably formed from the secretion of the *clitellum*, a peculiar thickening of the body wall, between the 29th and 35th segments. The clitellum is generally a very prominent band, forming one of the most noticeable of the external features of an earthworm, but it is not always evident. The eggs of earthworms contain considerable yolk, and the young worms develop without any metamorphosis.

Consult: Sedgwick and Wilson, *General Biology* (New York, 1895); Beddard, "Earthworms and Leeches," in *Cambridge Natural History*, vol. ii (New York, 1896); id., *Earthworms and their Allies* (New York, 1912).

EAR TRUMPET. A contrivance for improving the hearing of the partially deaf, and, as its name implies, a trumpet-shaped tube, whose action depends on the principles of reflection. The waves of sound strike the bell of the trumpet and are reflected into the narrower portion of the tube. As the waves proceed, the wave front narrows in breadth, but increases in intensity and the sound reaches the inner ear magnified. In a great number of cases of impaired hearing, there can be no doubt that much assistance is obtained from the use of the ear trumpet; still it must not be used indiscriminately, for in unsuitable cases it may do much mischief, both in increasing the deafness and aggravating the noises in the head from which deaf persons often suffer so much. It also possesses the great disadvantage of magnifying certain sounds at the expense of others. The ear trumpet, on account of its shape, acts as a resonator, and will strengthen and increase the vibrations of certain frequencies, while others will be almost destroyed. Ear trumpets are of most use, perhaps, in advanced cases of nervous deafness, though injurious in the early stages of this complaint; they are hurtful also in all acute diseases of the ear, and of little or no use in those cases of great thickening of the contents of the middle ear, where the adapting power of the organ has been lost. Most of the small and so-called invisible ear trumpets are considered practically useless. All of the useful instruments have good-sized bowls, which in some cases rest against the temple when inserted in the ear, thus aiding the hearing by bone conduction. Another variety, applicable to the more severe cases of deafness, consists of an elastic tube, one end of which is tipped with ivory and is placed in the ear of the patient; the other is held in the hand of the speaker, who applies his mouth to the open extremity. Ear trumpets are generally made of some thin metallic substance, such as tin. Gutta-percha and other substances are also frequently used. Various modifications of the telephone are now employed to reinforce the sound waves, and transmit them to the ear. See AUDIPHONE.

EAR WAX. See CERUMEN.

EARWIG (AS. *ēarwicga*, from *ēare*, Eng. *ear* + *wicga*, insect; connected with AS. *wieg*, horse, *wiht*, wight, from *wegan*, Icel. *vega*, Goth. *gawigan*, OHG., Ger. *wegan*, to carry, move; connected with Lat. *vehere*, OChurch Slav. *vešti*, Skt. *vah*, to carry, Gk. *ἔχειν*, *echein*, to hold). A popular name for orthopterous insects of the family Forficulidæ, resembling rove beetles, but easily distinguished from them by the presence of pincer-like processes at the posterior end of the abdomen. They probably owe their name to the foolish belief that they creep into the ears of sleepers. Earwigs are common in the United States only in the Southern States and on the Pacific coast. They are fond of moist situations, such as under the decayed bark of trees, under stones, among old straw, etc. They are nocturnal in habit, and while their food is chiefly vegetable, such as flowers and ripe fruit, they probably do much good by destroying numbers of thrips, aphids, etc. The name is also applied in the United States to several small centipedes which frequent houses.

AN EARWIG.

The three outline figures above show the extensive variability of the "tail-forceps" of the male of a single species (*Forficula auricularia*).

owe their name to the foolish belief that they creep into the ears of sleepers. Earwigs are common in the United States only in the Southern States and on the Pacific coast. They are fond of moist situations, such as under the decayed bark of trees, under stones, among old straw, etc. They are nocturnal in habit, and while their food is chiefly vegetable, such as flowers and ripe fruit, they probably do much good by destroying numbers of thrips, aphids, etc. The name is also applied in the United States to several small centipedes which frequent houses.

Fossil Earwigs. The earliest-known ancestor of the earwigs, a fossil genus (*Baseopsis*) from the Liassic rocks of Schambelen, Switzerland, is considered an interesting link connecting the Orthoptera and Coleoptera. Another Mesozoic genus is known in the Solenhofen limestones of Bavaria. Tertiary earwigs have been found in the amber of northeastern Prussia, in the beds of Aix, France, and Oeningen, Germany, and 11 species are known in the Oligocene shales of Florissant, Colo. These latter include some very large species with unusually large eyes. See ORTHOPTERA.

See bibliography under ORTHOPTERA; also de Bormans and Krauss, "Forficulidæ and Hemimeridæ," in *Das Tierreich*, ii. Lieferung (Berlin, 1900).

EAR WORM. The bollworm (q.v.). Also the cotton worm. See COTTON INSECTS.

EASEL (Dutch *ezel*, OHG. *esil*, Ger. *Esel*, Goth. *asilus*, AS. *esol*, *eosol*, from Lat. *asinus*, ass). A wooden structure, usually of tripodal form, upon which an artist places his canvas or panels when painting. The canvas is placed at a convenient height by means of pegs upon which is set a tray or supporting board, holes being bored in the two forward legs of the structure at regular intervals for receiving these pegs. This is the easel still in common use, though perhaps of earliest invention. Other forms of the easel, more mechanical in contrivance, are employed for large canvases.

EASEMENT. An acquired right of use or enjoyment in the lands of another, which one may have by virtue of his ownership or possession of other land. Though limited in number, easements are of very frequent occurrence, and comprehend such well-known rights as rights of way, of light, of drainage, and the like. They belong to that large class of rights, falling short of ownership, in the lands of others (*jura in re aliena*), which, from the point of view of the land subjected to the use, are sometimes called *servitudes*. The Roman law distinguished two

classes of servitude, urban and rural, and developed a refined and highly elaborated body of rules to determine the conflicting rights of the owner of the burdened land and of the person entitled to the use thereof. (See *SERVITUDE*.) In the common-law classification of property rights, easements belong to the class of incorporeal hereditaments, so called because they do not involve the possession of the land in which they are exercisable, as distinguished from the direct ownership coupled with the possession of a parcel of land, and because, like other real-property rights, they are inheritable with the lands to which they are appurtenant. They are limited in our system to real property, though the Roman law recognized servitudes in chattels, or movables, as well as immovables.

Though sometimes improperly used so as to include several varieties of rights in *alieno solo*, the easement proper is to be sharply distinguished: (1) from rights not acquired, but which flow directly from, and inhere in, the ownership of land, as the right to the uninterrupted flow of water in a watercourse, the right to the support of land in its natural state, etc., which are properly denominated *natural rights*; (2) from rights which do not consist in mere use, but which extend to the taking of something of value from another's land, as the right of pasturing cattle thereon, the right to mine coal or other minerals therein, and the like, which are known as *profits à prendre*, or, more briefly, as *profits*; (3) from rights of use which attach to a person as an individual and not as a property owner, and which are commonly spoken of as easements *in gross* as distinguished from easements *appurtenant*, but which are, strictly speaking, only *licenses* to use the land of another and not, therefore, inheritable or transferable as property rights (except in a few of the United States, where easements in gross have come to be recognized as property and as imposing a burden or servitude running with the land over which they are exercisable); and (4) from rights of use which pertain to one as a member of the public, such as the right to use a highway on another's land or to use a private stream for purposes of navigation, and which are sometimes improperly called public easements. See *NATURAL RIGHTS*; *PROFIT*; *LICENSE*.

As thus limited and defined, the term easement commonly describes only such a right of use as is appurtenant to a specific parcel of land to whose value and enjoyment it contributes. The right is, in fact, conceived of as belonging to the land, rather than to the owner thereof for the time being, and as burdening the land over which it may be exercised, and not the person having the actual possession thereof. Accordingly, the estate to which the right attaches is known as the dominant tenement, and the estate subject to the servitude as the servient tenement. It follows, also, that the easement is unaffected by any disposition which may be made of either estate. The servient estate is subject to it, into whosoever hands it may come, and the right of use passes with the dominant tenement, whenever that is conveyed. It was formerly considered that it was necessary to make some reference to the incorporeal rights attaching to an estate, at the time of conveying it, in order that these might pass with it to the grantee, and hence the use of the phrase "with the appurtenances" in modern deeds; but it has long been settled that these or any other

apt words are wholly unnecessary to produce that effect.

Easements are classified at common law as *positive* (or *affirmative*) and *negative*, the former having reference to such as involved the physical use of another's land by going upon it or otherwise, as a right of way or of drainage; while the latter, as in the right to light (see *LIGHT, EASEMENT OF*) or to the support of a party wall, calls for no such physical encroachment. While convenient for some purposes, this distinction is superficial and has no real significance, the duty of the owner of the servient tenement being in all cases purely negative—to refrain from so using his land as to interfere with the rights of the dominant tenement—and involving no obligation to repair or do any other affirmative act.

The infringement of an easement is commonly a nuisance, and may accordingly be abated, either by act of the party injured or by appropriate legal proceedings (see *NUISANCE*); and if the infringement be only threatened, or if the common-law remedy be inadequate to redress the injury committed, an injunction may be granted to restrain the acts complained of. (*INJUNCTION; TORT*.) But an easement is a true property right, or right in rem, and is protected not only against the acts of the owner or possessor of the servient tenement, but against those of any person whatsoever, the same remedies being available in the one case as in the other. Where a right in the nature of an easement exists which is not thus protected, such as might arise by contract between two adjoining landowners, this is a mere right in personam, a license, and not an easement or a property right at all. A contract, however formal, can never create a legal interest in land, though it may under certain circumstances give rise to an action against the owner of the land as such or as trustee in equity restraining him from acting in violation of his agreement.

Easements may arise in three ways, the second and third of which are, by a legal fiction, mere forms or variations of the first. These are: (1) grant, or deed; (2) prescription; and (3) implication. The deed of grant has from the earliest period of the common law been the peculiar and appropriate instrument for the creation and transfer of an incorporeal interest in land, corporeal interests, such as freehold estates, being formerly conveyed only by the process known as livery of seisin, i.e., by an actual physical transfer of possession. By prescription is meant a right acquired by long and uninterrupted use and enjoyment from time immemorial, which, in the view of the law, created a presumption of a grant of the right claimed at some remote period of time. Formerly this presumption could be shown to be unfounded and the claim thus defeated, but in the United States, and for most purposes in England, the presumption of a lost grant, as it is termed, is a pure fiction, and is no longer requisite to establish an easement by prescription. Easements by implication are such as arise from a legal presumption of the intention of the parties at the time a parcel of land is conveyed. Perhaps the best illustration of such an easement is what is known as a "way of necessity," which exists where one buys premises which are shut off on all sides by intervening land from access to the highway. Here the easement arises, not from the necessity

of the case, but from a reasonable presumption that the grantor of the landlocked parcel intended to give with it a right of way over his remaining land.

Of these several ways of creating easements, the first is the most comprehensive. All easements may arise by grant, and some only in that way. In the United States it is generally considered that negative easements, such as the easements of light, of lateral support, and the like, cannot exist by prescription, though the contrary view is taken in a few of our States. On the other hand, only a few classes of easements will arise by implication—such, that is to say, as involve a "continuous and apparent" user of the premises affected, as an aqueduct or drain. There is much difference of opinion as to what easements are properly to be described as continuous and apparent, negative easements being included in some jurisdictions and excluded in others, and the decision being sometimes made to turn on the question whether a permanent structure, like a drain, was actually apparent and known to the parties at the time of the conveyance.

Easements may be lost or destroyed, either by release, by merger, by abandonment, by license, or, in some cases, by destruction of the premises to which they attach. Merger occurs where the dominant and the servient estates become vested in the same person. Here the easement will not revive upon the subsequent conveyance of either of the estates to another person. It is not true, as is often said, that an easement may be lost by mere nonuser. But if the nonuser be under such circumstances as to show an intention to abandon the easement, it may be lost through the act of the servient tenant in accepting the abandonment by obstructing the easement. So where the dominant tenant licenses the owner of the servient estate to plow up a way or obstruct the former's light, the license, once acted upon, is irrevocable and the easement at an end. Mere misuse of an easement is as inoperative to destroy it as nonuser. Such a right must be exercised within narrow limits, however: nothing may be done by the dominant tenant which materially increases the burden upon the servient tenement; neither may he make any material change in the manner of exercising it; but the remedy for an excessive user of an easement is an action of trespass and not the forfeiture of the right which has been abused. It is not, however, an unlawful or excessive user of an easement to enter upon the servient premises from time to time for the purpose of repair and of keeping the easement in good working order, nor for the purpose of abating a nuisance which interferes with its enjoyment.

It is only in the case of an easement of an ephemeral or temporary character that it is lost by any injury to the premises. The destruction of a road by flood or earthquake does not affect the right of way which exists with reference to it. The person claiming the easement may, at his own cost, make whatever repairs are necessary to restore the way to its former condition. So, if a house having an easement of light be destroyed by fire, the easement is not lost, but revives on the rebuilding of the house. But easements of lateral support, such as those which attach to party walls, are manifestly intended only for the houses which are supported by such walls, and the complete destruction of

the premises has the effect of destroying the easements on both sides. Either party may thereupon rebuild on his own land at his own pleasure and without reference to his neighbor. However, if the party wall is not completely destroyed, but is susceptible of repair or reconstruction, it may be restored by the party desiring to avail himself of the easement, at his own expense, and his right to the support of the wall continues as before.

The narrow range of the class of rights under consideration, the restrictions which the law imposes upon their creation and exercise, have been made clear by the foregoing explanation of their legal character and status. This jealous attitude of the law towards rights of this character is due to the fact that they always constitute an interference with the free exercise of his natural rights by the owner of the servient tenement. The easy creation and the indefinite duration of such rights would produce grave inconvenience and would seriously hamper the enjoyment of real property. Hence the common law has still further restricted them by arbitrarily limiting their number. It is a maxim of the law that no novel easements can be created. Landowners are limited to the kinds which have always been known, and which have previously been recognized by the courts as proper and convenient burdens upon land. Those already referred to—ways, lights, drains, water-course, support to buildings—constitute practically all, or nearly all, the easements which can be created. Attempts have been made to increase the number, but the courts have invariably refused to countenance such proposed additions to the list, as the right of a householder to erect a mill or a chimney, the right to erect a windmill, view, etc. Such a right may, indeed, be conferred upon one man by another, but it remains a mere right in personam, a contract right, and does not become a burden upon the land of the grantor or an appurtenance to the estate of the grantee. The only exception to this principle is that furnished by the case of the "equitable easement," whereby a restrictive covenant affecting the use of land—as an agreement not to build within a certain distance of the street line—is enforceable in equity—not only against the maker of the covenant and his heirs, but also against his assigns who take title with notice of the covenant. But even this exception, important though it be, is usually limited to a narrow range of cases, in which the covenant sought to be enforced is purely restrictive in character and imposes no active duty upon the owner of the premises affected. See **EQUITABLE EASEMENT**.

Analogous to easements in their effects, but differing fundamentally from them in character, are the rights which are loosely described as "covenants running with the land." It has already been stated that an easement cannot be created by covenant—which is only a contract under seal—but requires the ancient form of a grant. Interests, or estates, in real property, whether corporeal or incorporeal, are too important to be subject to creation or transfer by any but the most solemn legal forms. Hence a contract affecting the use of land, like any other contract, creates only a right in personam, a right of action on contract, and not an interest in the property itself. But if such right of action runs with the land, that is, if it binds anybody and everybody who becomes the owner

of the land, and if, on the other hand, it is enforceable, not only by the person to whom the promise is made, but by everybody who becomes entitled to the promisee's land, it is evident that we have the substance if not the form of an easement. The method of enforcing the right is different, by an action in covenant instead of trespass; but the right, on the one hand, and the burden, on the other, are not otherwise distinguished from those resulting from an easement. A very limited class of cases, such rights, arising out of covenant, are recognized in our law. The essential conditions are: (1) that the covenant shall "touch and concern" the land, that is, that it shall affect the use and condition of the premises; and (2) that there shall be privity of estate, that is, some such relation as that of landlord and tenant, between the parties. In other words, both parties must in some way have an interest or estate in the parcel of land affected by the covenant. Thus, if a tenant covenants to make repairs, or to cultivate the land in a certain way, the right to enforce such covenant will pass to the landlord's assignee, and the obligation to perform it will be equally incumbent on the tenant's assignee as upon the original tenant who entered into the engagement. In a few American jurisdictions this principle has been extended to the case of the privity existing between the owners of a dominant and a servient tenement, respectively, so that a covenant by the latter to keep a private way over his land in repair for the benefit of the former would pass as a permanent burden with the land; but this extension of the common-law doctrine is not generally accepted in the United States nor in England.

There is, of course, no element of easement in the other class of cases to which the expression "covenant running with the land" is applied—those, namely, where, there being no relation of privity of estate, a covenant for the benefit of a parcel of land, by whomsoever made, is enforceable by those to whom the land may pass by descent or otherwise, against the covenanting party. Here we have the exact reverse of what is erroneously termed an easement in gross—the latter being a right in land claimed by an individual in his own capacity, and the former a right in the land, or in its tenancy for the time being, against an individual. There being no privity, there is no easement, which, as has been said before, requires both a dominant and a servient tenement. See **INCORPoreal; HEREDITAMENT**.

The authorities are modern, the law on the subjects of easements being of a very meagre character prior to the nineteenth century. Consult: Holland, *The Elements of Jurisprudence* (9th ed., New York and Oxford, 1900); Gale, *Easements* (7th ed., London, 1899, 8th ed., Toronto, 1908); Goddard, *Easements* (6th ed., London, 1906); Washburn, *Easements* (6th ed., Boston, 1885); Jones, *Treatise on the Law of Easements* (Boston, 1898); Inness, *Law of Easements* (8th ed., London, 1911).

EASLEY. A city in Pickens Co., S. C., 12 miles west of Greenville, on the Pickens and the Southern railroads (Map: South Carolina, B 2). It is in a fertile cotton region and has cotton, oil, and flour mills. Pop., 1900, 903; 1910, 2983.

EAST, SIR ALFRED (1849-1913). An English landscape painter and etcher. He was born at Kettering, and studied at the Glasgow Art

School, at the Ecole des Beaux-Arts, Paris, and under Fleury and Bouguereau. He painted usually in a low key, with great breadth and freedom of handling, and sought to render effects of light and color rather than definite line. His art is a direct interpretation of nature, possessing a strong lyrical quality and revealing a subtle personality. His water colors are forceful yet delicate in treatment, and his etchings are spontaneous and original. He best interpreted English landscape, but displayed his versatility in studies of America and of Japan, which he visited in 1889. East was elected president of the Royal Society of British Artists in 1906, a member of the Royal Academy in 1913, and was knighted in 1910. He was honorary member of the Japanese Meiji Bijutsu Kai and of the academies of Rome, Milan, and Stockholm, and received many medals and honors. His works were frequently exhibited in Europe and America. Among his paintings in public galleries are: "Evening in the Catswolds" (Hull); "A Passing Storm" (Luxembourg); "Haunt of Ancient Peace" (Budapest); "The New Valley" (Venice); "London at Night" (Milan); "Returning from Church" (Carnegie Gallery, Pittsburgh); "The Moon" (Chicago); "Autumn" (Manchester). He was the author of *The Art of Landscape Painting in Oil Color* (1906).

EAST AFRICA COMPANY, BRITISH. A commercial association, founded after the Berlin Treaty of 1885, to develop African trade in the territory controlled by the English.

EAST AFRICA COMPANY, GERMAN. A trading company, formed in 1885, to develop the African territory under German influence.

EAST AFRICA PROTECTORATE. A British dependency extending from German East Africa to Italian Somaliland and Abyssinia, and from the Indian Ocean inland to Uganda (Map: Africa, H 4). It includes seven provinces (each under a provincial commissioner) and a tract of territory in the northwest partly organized; together with certain territories leased from the Sultan of Zanzibar (a 10-mile-wide strip along the coast from the German frontier to Kipini, the islands of the Lamu Archipelago, and a 10-mile tract between Kismayu) at an annual rental of £17,000. The area of the protectorate is estimated at 250,000 square miles. The coastal districts are fertile and enjoy a climate healthful in comparison with that of other tropical regions; and here are grown rice and other cereals, coconuts, cotton, sisal, rubber, and tobacco. The central highlands have a more temperate climate and produce in export quantities potatoes, fruits, sim sim, and beans; other cultivated products are coffee, wheat, and barley. Stock raising is a growing industry, the extensive upland pastures furnishing grazing for cattle, sheep, and ostriches. In the south great tracts of wiregrass give cover to herds of wild animals. Ukamba and Naiyasha provinces are the most suitable for European colonization. From the highland forests come croton, olives, figs, and timber; the coast regions yield rubber, gum copal, mangroves, and timber; while in the interior lowlands are found acacia and ebony. No exact information exists concerning the country's mineral resources in detail: iron is generally distributed; in Ukamba, carbonate of soda, mica diatomite, and graphite are found; opals are present in the valley of the Rift; limestone is worked, but gold mining

has ceased. The disposal of land in 1911 was as follows: 4941 acres freehold (6216 in 1910; 10,348 in 1909; 32,795 in 1907), 603,811 lease (383,382; 363,222; 538,573). Of the total 7370 were (19,852; 18,394; 26,126) and (369,746; 350,575; 327,939). The growth of the trade is seen in the table below:

YEARS	Imports*	Exports	Customs
1903-04 ...	£436,947	£159,815	£33,159
1905-06 ..	672,360	332,838	78,718
1907-08 ..	799,717	515,052	81,655
1909-10 ..	775,246	590,057	84,289
1910-11 ..	1,000,346†	962,911	99,508
1911-12 ..	1,330,437	1,016,898	122,940
1912-13 ..	1,808,343	1,203,201	

* Exclusive of railway material, administration stores,

£66,382 for material for the Magadi Railway.

Shipping entered and cleared: 2,886,331 tons in 1911-12; 2,566,731 in 1910-11; 1,762,243 in 1908-09. The protectorate government operates the Uganda (Mombasa-Victoria) Railway; length, 586 miles. The cost of construction, to March 31, 1912, was £5,734,335. In connection with the railway, four steamers are operated on the lake. The revenue is derived from customs, port, harbor, etc., dues, licenses and taxes, court fees, posts, telegraphs, and railways, etc., and amounted in 1912 to £729,078. The expenditure was for the same year £961,178, and the grant in aid, in 1911-12, £115,000. The Treasury advanced £250,000 in 1911 and £375,000 in 1912 for public works, and in 1912 the grant in aid was suspended.

For a brief period the protectorate was, with Uganda, administered by the Imperial British East Africa Company, the original grantee; but in 1895 it was transferred to a commissioner and commander in chief under the Foreign Office. In 1905 it was again transferred from the control of the Foreign Office to that of the Colonial Office. In 1906 an order in council constituted the administrator a governor and provided for executive and legislative councils. Lieut. Col. J. Hayes Sadler was the first governor and commander in chief. Nairobi is the administrative headquarters and the central station on the Uganda Railway, with 14,000 inhabitants (700 Europeans). The largest town and chief port is Mombasa, with about 30,000 inhabitants (230 Europeans). Kilindini possesses the finest harbor on the east coast and is to have extensive improvements. A recent estimate gives 4,038,000 for the population. The coastal population is largely Mohammedan; in the interior pagan, Bantu-speaking tribes predominate; other non-Bantu tribes are the Masai, the Somalis, and the Gallas. Consult: Purvis, *Handbook of British East Africa and Uganda* (London, 1900); *British Empire Series* (ib., 1899); *The Rise of our East African Empire* (ib., 1893); Lugard, *British East Africa and Uganda* (ib., 1892); Eliot, *East Africa Protectorate* (ib., 1905). Consult also the publications of the Colonial Office of Great Britain.

EAST ANGLIA, ȁnglĭ-ā. See ANGLIA, EAST.

EAST AURORA. A village in Erie Co., N. Y., 17 miles southeast of Buffalo, on the Pennsylvania Railroad (Map: New York, B 5). It is noteworthy as the home of the Roycrofters, whose shop produces fine handmade furniture

and editions de luxe of current and standard books. There are also roller mills and agricultural-implement works. The village contains a covered mile race track and mineral springs. The water works and sewerage plant are owned by the municipality. Pop., 1900, 2366; 1905, 2448; 1910, 2784.

EASTBOURNE, *ĕst'bôrn*. A county borough and seaside resort in Sussex, England, situated on the coast between Hastings and Brighton, about 3 miles northeast of Beachy Head (Map: England, G 6). It is well built, with broad, tree-lined streets, lighted by electricity. A fine esplanade nearly 3 miles long skirts the shore. Devonshire Park (13 acres) and numerous smaller recreation grounds are maintained by the municipality. The town hall, erected in 1886, is a handsome building. Eastbourne was incorporated in 1883 and in 1911 was made a county borough. The borough owns its electric-lighting plant, motor-omnibus lines, isolation hospital, technical institute, etc. It has established an excellent system of drainage and a good water supply from wells, all of which, combined with its healthful situation, have made it one of the most popular of south-coast resorts. Pop., 1901, 43,574; 1911, 52,544.

EAST BRIDGEWATER. A town in Plymouth Co., Mass., 24 miles south of Boston, on the New York, New Haven, and Hartford Railroad (Map: Massachusetts, F 4). The chief industries comprise an iron foundry and a cotton gin. Pop., 1900, 3025; 1910, 3363.

EAST CAPE. The name of the easternmost headland of Asia (coast of Siberia). It is situated in lat. 66° 3' N. and long. 169° 44' W. and is separated by Bering Strait from Cape Prince of Wales in America (Map: Asia, R 2).

EAST CHEAP (*ME. Ēstchepe*, east market, from AS. *ĕast*, east + *cĕap*, traffic). Originally an open space in which a market was held for the East of London. It was situated at the junction of several streets, the oldest and most important of which were the two great Roman roads, leading northwest and northeast out of London. These roads were known in Saxon times as Watling and Ermine streets and met on the north side of London Bridge. On account of its situation on these roads Eastcheap was famous at a very early date for its taverns; and the "Boar's Head at Eastcheap," of Shakespeare's Prince Hal and Falstaff, was probably thus known as early as the reign of Edward III. The name is still preserved in that of a small street, near the north end of London Bridge.

EAST CHICAGO. A city in Lake Co., Ind., 22 miles by rail southeast of Chicago, on the Pennsylvania, the Wabash, the Pere Marquette, the Baltimore and Ohio, Chicago Terminal, the Chicago, Indiana, and Southern, and the Indian Harbor Belt railroads, and on Lake Michigan (Map: Indiana, B 1). The chief industries are the manufacture of iron and steel, cement, lumber, boilers, hay presses, chains, chemicals, and foundry products. East Chicago has a good harbor, and its shipping facilities have been greatly enhanced by the construction of a canal, connecting the harbor with the Calumet River. Bascule bridges and turning basins have been provided. The city is governed by a mayor and a unicameral council of six members. East Chicago was incorporated as a town in 1889 and as a city in 1893. Since then its growth has been very rapid. Pop., '900, 3411; 1910, 19,098; 1914 (U. S. est.), 25,781.

EAST CLEVELAND. A city in Cuyahoga Co., Ohio, 5 miles east of Cleveland (Map: Ohio, G 2). It has laboratories of the National Electric Lamp Associations. The city is essentially a residential suburb of Cleveland and contains the beautiful summer estate of John D. Rockefeller, comprising more than 700 acres. Pop., 1900, 2757; 1910, 9179; 1914 (U. S. est.), 11,914.

EAST CONEMAUGH, *kōn'ĕ-mā'*. A borough in Cambria County, 32 miles (direct) southwest of Altoona, on the Pennsylvania Railroad, and on the Conemaugh River (Map: Pennsylvania, D 6). The chief industry is the manufacture of steel. Conemaugh contains railway shops and owns its electric-light plant. The borough was partially destroyed by the Johnstown flood in 1889. Pop., 1900, 778; 1910, 1549.

EAST END. A thickly populated and poor district of London, east of the Bank of England.

EAST END. In architecture, the altar end or chancel end of a church, as opposed to the west front or entrance end. It has been the nearly universal practice ever since the fifth century to orient the church building so that the priest at the altar and the congregation may both face the east in worship. In the earliest churches, as in pagan temples, the entrance was in the east end, and the officiating priest faced the worshippers. This orientation (q.v.) was preserved in St. Peter's at Rome, but was generally given up at an early date in favor of the present practice. The architectural treatment of the east end is a distinguishing mark of various styles. Except in many English cathedrals and churches, and Cistercian churches elsewhere which have square east ends, the central aisle of the chancel generally terminates eastward in an apse, with or without an ambulatory, apsidal chapels, etc. See EAST WINDOW; APSE; CHURCH; CHANCEL; GOTHIC ARCHITECTURE; ORIENTATION.

EASTER (AS. *ĕastre*, OHG. *ĕstarā*, Ger. *Ostern*, from Teut. *Austrō*, goddess of spring; connected with Lat. *aurorā*, Gk. *hḗs, ĕōs*, with AS. *ĕast*, and ultimately with Gk. *hēmar*, day, Lat. *ver*, spring). The festival of the resurrection of Christ, the principal feast of the Christian era. From very early Christian times it was observed with great solemnity. In the primitive Church it was one of the special days for the administration of baptism, and the Latin name of the octave or the Sunday following, *Dominica in Albis*, preserves the memory of the custom of the newly baptized wearing their white robes throughout the whole week. The faithful greeted each other with the kiss of peace and the salutation "Christ is risen," to which the response was, "He is risen, indeed." This custom is still kept up in Russia. In the Catholic church the festivities of Easter really begin on the preceding morning with the mass of Holy Saturday, in which the short first vespers of Easter are included—a trace of the times of primitive severity, when the mass of that day was celebrated in the evening.

The proper time for the celebration of Easter has occasioned much controversy. In the second century a dispute arose on this point between the Eastern and Western churches. The great mass of the Eastern Christians celebrated Easter on the Jewish Passover, the fourteenth day of the first Jewish month or moon, thinking of Christ as the true Paschal Lamb. The Western churches celebrated it on the Sunday after the fourteenth day, holding that it was the commemoration of

the resurrection of Jesus. The Council of Nicæa (in 325) decided in favor of the Western usage, branding the Eastern with the name of the "quartodeciman" heresy. This, however, only settled the point that Easter was to be held, not upon a certain day of the month or moon, but on a Sunday. The proper astronomical cycle for calculating the occurrence of the Easter moon was not determined by this council. It appears, however, that the metonic cycle (q.v.) was already in use in the West for this purpose; and it was on this cycle that the Easter moon introduced in 1582, was arranged. The time of Easter, being the most important of all the movable feasts of the Christian Church, determines all the rest. It was debated, at the time of the introduction of the Gregorian calendar, whether Easter should continue to be movable, or whether a fixed Sunday, after the 21st of March, should not be adopted. It was deference to ancient custom that led the ecclesiastical authorities to adhere to the method of determination by the moon. It must be remembered, however, that it is not the actual moon in the heavens, nor even the mean moon of astronomers, that regulates the time of Easter, but an altogether imaginary moon, whose periods are so contrived that the new (calendar) moon always follows the real new moon (sometimes by two, or even three, days). The effect of this is that the fourteenth of the calendar moon—which had from the times of Jewish law been considered the "full moon" for ecclesiastical purposes—falls generally on the fifteenth or sixteenth of the real moon, and thus after the real full moon, which is generally on the fourteenth or fifteenth day. With this explanation, then, of what is meant by full moon, viz., that it is the fourteenth day of the calendar moon, the rule is that Easter Day is always the first Sunday after the paschal full moon, i.e., the full moon which happens upon or next after the 21st of March (the beginning of the ecclesiastical year); and if the full moon happens upon a Sunday, Easter Day is the Sunday after. The adoption of the Gregorian calendar (see CALENDAR) changed the date of Easter. The Greek church, which did not accept the Gregorian calendar, therefore usually celebrates Easter on a different day from the Western church.

One object in arranging the calendar moon was that Easter might never fall on the same day as the Jewish Passover. They did occur together, however, in 1805, in 1825, and in 1903, on the 12th of April, and will do so again in 1923 on the 1st of April, in 1927 on the 17th of April, and in 1981 on the 19th of April. The Jewish Passover usually occurs in the week before Easter, and never before the 26th of March or after the 25th of April. On the other hand, the Christian festival is never before the 22d of March or after the 25th of April. In 1761 and 1818 Easter fell on the 22d of March, but this will not be the case in any year of the twentieth century. The latest Easter in this century occurs in 1943, on the 25th of April.

The popular observances, past and present, connected with the day are innumerable. The use of eggs in this connection is of the highest antiquity, the egg having been considered in widely separated pre-Christian mythologies as a symbol of resurrection. It is probable that here, as in other cases, the Church adopted and consecrated an earlier custom. This is certainly true of the Easter fires which formerly celebrated the

triumph of spring over winter. (See BELTANE.) Some of the mediæval customs, especially in France and Germany, were very quaint—e.g., that which prevailed in several French cathedrals of a solemn game of ball played by the bishops, canons, and other dignitaries (described by Pater in one of his *Imaginary Portraits*); grave and rhythmical dances were performed at Auxerre as late as the fifteenth century and at Besançon as late as the seventeenth century, to the strains of the Easter sequence, *Victima paschali*. All these observances had a common purpose, the expression of joy in the resurrection. To the popular sports and dances (still maintained in some places, as at Constantinople, where the whole Greek colony celebrates the festival with the ordinary accompaniments of a fair in the cemetery of Pera) were added farcical exhibitions, in which even the clergy joined in some places, reciting from the pulpit stories calculated to excite laughter (*risus paschalis*). Easter customs form an important part of popular survivals in religion.

EASTER ISLAND (so called because discovered by Roggeveen on Easter, April 6, 1722). There is reason to identify this island with a discovery made by Davis the buccaneer in 1686, and the Spanish geographers assign the credit to Alvaro Mendaña in 1566. The island has no name in the language of its inhabitants; Foster's name, *Vaihu*, is the name of a landing place on the south shore; Cook's *Teapey* means no more than gorge and was of local application to a narrow way; *Rapanui* is a modern invention; *Te Pito te Henua* is merely any one of its three corner capes. It is the most eastern site of Polynesian habitation and lies in lat. 27° 20' S. and long. 109° 30' W. (Map: Western Hemisphere, M 10). The island, triangular in shape, is a volcanic formation, with three craters at each apex of the triangle, and reaches a height of 1200 feet, but there is no evidence of present volcanism. The area is about 45 square miles, the soil thin and poor, water almost absent, timber scanty and not higher than bushes. The island was almost depopulated by vessels in the Chilean labor trade which carried away the men to work on the *Chincha Islands*; at present not more than 150 survive on Easter Island. The island has been an unorganized dependency of Chile since 1888. The particular interest which attaches to Easter Island is dual: it is the richest site of the megaliths of the Pacific; it is the unique source of incised tablets or *hyloglyphs* in the island realm.

The megaliths of Easter Island occur in three forms, all cyclopean. Upon the bluffs and in other sites commanding a view of the sea great platforms have been built, with neatly fitted facing stones set without mortar and the inner area filled with rubble. In the survey conducted by officers of the U.S.S. *Mohican* 113 such platforms have been measured, each known by name to the older inhabitants. The largest platform is known as *Tongariki*, 150 feet long, 9 feet wide, 8 feet high, original extent, with wing annexes, 140 feet. Into the construction of the platform known as *Ohau* entered a stone weighing six tons; the platform *Anaoraka* shows the largest stones, one on the sea face measuring on its exposed surface 6 feet, 9 inches high and 4 feet, 7 inches wide. In the neighborhood of many of the platforms are

found semisubterranean inclosures, conveniently called houses, although their purpose is unknown. These are built of great stones artfully fitted and in many instances are decorated with pictographs, either colored by rubbing with tufa and shell or incised, or both. Many of the designs are identical with figures on the hyloglyphs; for this reason the mural painting may be considered modern, though older than present memory. The most conspicuous units of all this stonework are the statues rudely carved after the manner of terminalia—a head with exaggerated ears, a neck and shoulders. The *Mohican* survey discovered 555 statues; the largest measures 70 feet in length and lies unfinished in the quarry at Rano Raraka; the largest which has been put in position on a platform is 32 feet long and weighs 50 tons. The material of the statues is gray trachytic lava. Upon the head of each statue when erected upon the platforms was set a cylinder of red vesicular tufa of an average weight of three tons, the largest one measuring 12 feet, 6 inches in diameter. The traditions of the Easter Islanders are not explicative, and it is most reasonable to regard the megaliths as surviving from an antecedent culture.

The *hi'anga's* are small pieces of wood covered with finely incised figures highly conventionalized. Twelve tablets have been collected, and all are preserved save one. The tablets are grooved in shallow channels, and the design is cut in the bottom of the grooves. The few islanders who profess ability to read these records begin at the lower left-hand corner of the tablet, read to the right to the end of the line, invert the tablet and read the second line, and so on in a modified boustrophedon, for in each alternate line the characters have been cut upside down. The reading is far from satisfactory; a version printed in the *Journal of the Polynesian Society* by Dr. A. Carroll, of Sydney, purports to give a record of events in the pre-Inca-Andean culture, but the author did not divulge his method; the version of several tablets recorded by Thomson is very faulty, since it is neither in the language of Easter Island nor in any known Polynesian speech. It is clear that these hyloglyphs, while immemorial, are recent, and, if it can be established that they are literal or syllabic, they form the only instance in which the South Sea Islanders have approached the art of writing, except for a syllabary reported in 1914 from the Caroline Islands as in esoteric use by a few aged chiefs.

The composition and the period of the migration swarm which peopled Easter Island have been established by philological analysis. The nearest affinity is with the Tuamotu (q.v.), showing that at some period the two races were in contact. After deduction of the element of language common to the Tuamotu, the residuum is found to consist of a proto-Samoan element, whose home was in that western archipelago until a period corresponding with the Norman Conquest of England. The settlement of Easter Island cannot have taken place more than 10 centuries ago, and there is reason to regard it as much more recent. Consult: Geiseler, *Die Osterinsel, eine Stätte prähistorischer Kultur* (Berlin, 1883); Thomson, "Te Pito te Henua, or Easter Island," in the *Report of the United States National Museum* (Washington, 1891); Cooke, "Te Pito te Henua," *Report of the United States National Museum* (ib., 1899); Gana,

Viaud, and Ballesteros, *La Isla de Pascua* (Santiago de Chile, 1903); Churchill, *Easter Island, the Rapanui Speech and the Peopling of South-east Polynesia* (Washington, 1912).

EASTERN QUESTION. The complicated problem of international politics growing out of the relations of Turkey, the Balkan nationalities, and the Great Powers of Europe to each other and to one another. The problem has occupied the attention of Europe, in more or less degree, since the second half of the eighteenth century, when the rapid curtailment of the Ottoman power "ترک" Turkish advance southward seemed to threaten the establishment of Russian supremacy in the southeast of Europe at the expense of Austria. In the nineteenth century the decline of Turkey chiefly concerned only these two powers. Subsequently, however, the interests of Great Britain became more closely bound up with the fortunes of the Turkish Empire as the importance of the British possessions in India increased, and with it the necessity of preserving a safe and short line of communication between England and the Far Orient. France, too, was involved in the web of diplomacy, first and naturally, as one of the Great Powers; secondly, because of its ancient connection with the Porte; and, thirdly, because of the development resulting from the ambitious schemes of Mehmet Ali (q.v.), of Egypt. Germany, until the very last years of the nineteenth century, disclaimed all interest in the Eastern Question; but at that time German capital had not yet entered extensively into railroad and other business enterprises in Syria, which at present have resulted in establishing close relations with the Ottoman government. The Eastern Question entered upon its modern phase in the Crimean War (q.v.) and assumed definite form at the Congress of Paris in 1856, whose work was slightly modified by the London Protocol of 1871. The opening of a new highway to the East by the Suez Canal and the English occupation of Egypt have helped to complicate the Eastern Question. A new phase of it developed when Russia began a war with Turkey in 1877. The new status created by this war, the full results of which Russia was not allowed to reap, was embodied in the treaty arrangements of the Congress of Berlin (q.v.). This arrangement held through the remainder of the nineteenth century, although considerable changes took place through the annexation of eastern Rumelia to Bulgaria in 1885, the shifting of the boundary between Greece and Turkey as a result of the War of 1897, and the establishment of autonomy in Crete.

Though affairs in eastern Asia have diverted attention from the Eastern Question proper, the problem is still a vital one and fraught with great importance to the future development of international relations. Russia still has her eye on Constantinople; Great Britain must still defend her position in Egypt; above all, Austria-Hungary must in very self-preservation retain her influence among the Slav peo-

ples of the Balkans. The balance of adjustment is delicate, with Austrian influence predominant in Serbia, with Russian influence powerful in Bulgaria, and Greece still anxious to restore in some measure the ancient Byzantine or Greek Empire. In 1909, however, the status quo was suddenly revolutionized. The coup d'état of the Young Turks in the Ottoman Empire; the proclamation of Bulgaria's independence, and the assumption by Bulgaria of the title of Czar; the seizure of Bosnia and Herzegovina by Austria upset entirely the arrangements made at Berlin. The triple alliance of Germany, Austria, and Italy found itself confronted by the triple entente of Russia, France, and Great Britain. Italy in 1911 pounced upon Tripoli (q.v.). A year later the Balkan War (q.v.) drowned the Balkan Peninsula in the most sanguine conflict that war-acursed territory has ever experienced. From that conflict Greece has emerged triumphant; Serbia has largely extended her frontier; Bulgaria somewhat less so; Rumania has gained territory of great economic value; Albania appears as a new country, and Turkey in Europe has shrunk to pitiful dimensions. The Eastern Question, with the exception of the Bagdad Railway problem (q.v.), is primarily concerned with the rivalry between Greece and Italy, Bulgaria and Serbia, Austria and Russia, as to their respective spheres of influence. Consult Holland, *Studies in International Law* (Oxford, 1898), and Hichens, *The Near East* (London, 1913). Consult also the bibliographies under BALKAN WAR, GREECE, TURKEY, BULGARIA, ETC.

EASTERN RITE, CHURCHES OF THE. The name given to various bodies of Armenian, Coptic, Greek, and Syrian Christians, most of whom were formerly Nestorians or Eutychians, but who have acknowledged the supremacy of the Pope and returned into communion with Western Christendom. They are commonly known as Uniat churches. See UNIATES.

EASTERN RUMELIA. See RUMELIA, EASTERN.

EASTERN SHORE. See MARYLAND.

EASTERN STAR, ORDER OF. A woman's fraternal organization, founded in 1776 and affiliated with Masonry. It had, in 1913, 51 grand chapters and 7500 subordinate chapters and a membership of about 700,000. Its officers are grand matron, grand secretary, and grand treasurer.

EASTER TERM. One of the four regular terms of the courts of common law in England. It was formerly dependent upon the movable feast of Easter and was hence called a movable term. It commenced on the Wednesday fortnight after Easter Sunday and lasted till the following Monday three weeks. It was at a later period converted by act of Parliament into a fixed term, beginning on the 15th of April and ending on the 8th to the 13th of May in every year. If any of the days between the Thursday before and the Wednesday after Easter fall within term, no sittings in banc (q.v.) are held on those days, and the term is prolonged a corresponding number of days. See TERM OF COURT.

EAST FLANDERS. See FLANDERS, EAST.

EAST GRAND FORKS. A city in Polk Co., Minn., 24 miles northwest of Crookston, on the Great Northern and the Northern Pacific railroads (Map: Minnesota, A 3). It is in an agricultural district and carries on an extensive

trade in liquors. The water works are owned by the city. Pop., 1900, 2077; 1910, 2533.

EAST GREENWICH, GRINJ. A town and the county seat of Kent Co., R. I., 13 miles south of Providence, on the New York, New Haven, and Hartford Railroad, and on Greenwich Bay, a branch of Narragansett Bay (Map: Rhode Island, C 3). There is a good harbor, also a public library and an academy. The town has a cotton bleachery, dry salter works, and manufactures of dextrin, cotton, and yarn. Pop., 1900, 2775; 1910, 3420.

EAST HAM. See HAM, EAST AND WEST.

EASTHAMPTON. A town, including three villages, in Hampshire Co., Mass., situated in the valley of the Connecticut, $4\frac{3}{4}$ miles south by west of Northampton, on the New York, New Haven, and Hartford, and the Boston and Maine railroads (Map: Massachusetts, B 3). There is a large dyeing and mercerizing plant and manufactories of drop forgings, rubber and elastic goods, buttons, shoe web, cotton goods, felt, and yarns. Easthampton has a public library and the Williston Seminary, a well-known preparatory school for boys. The government is administered by annual town meetings. The water works are owned and operated by the municipality. Easthampton was first settled in 1665, was incorporated as a district in 1785, and was organized as a town in 1809. It was the scene of an Indian massacre on May 13, 1704, in which 19 persons were killed. Pop., 1900, 5603; 1910, 8524; 1914 (U. S. est.), 9768.

EAST HAMPTON. A town in Suffolk Co., N. Y., at the east end of Long Island, on the Long Island Railroad, 102 miles from New York City. It is noted for its picturesqueness and is a popular summer resort. The building of the Clinton Academy, incorporated in 1784, is now used as a library and town hall. At Montauk Point, near here, an army camp was established after the Spanish-American War. The government is administered by town meetings, held biennially. The town, settled in 1649, came under the jurisdiction of Connecticut in 1657 and under that of New York in 1664. During the Revolution it was frequently pillaged by the English. Pop. (town including part of Sag Harbor village), 1900, 3746; 1910, 4722. Consult Hedges, *History of the Town of East Hampton* (Sag Harbor, 1897), and Gardiner, *Records of East Hampton* (ib., 1886-89).

EAST HARTFORD. A town in Hartford Co., Conn., 2 miles east of Hartford, on the New York, New Haven, and Hartford Railroad, and on the Connecticut River (Map: Connecticut, E 2). It has a town library and the Raymond Library, and a cemetery dating back to 1710. The chief industries are paper making, tobacco growing, and market gardening. There are also railroad and machine shops. East Hartford was settled in 1640-50 and was incorporated in 1783. The government is administered by town meetings. Pop., 1900, 6406; 1910, 8138; 1914 (U. S. est.), 8875. William Pitkin, one of the Colonial governors, was born here. Henry Howard Brownell, the "Battle Laureate" of America, died here.

EAST HUMBOLDT MOUNTAINS. A range of lofty mountains in Elko Co., Nev., about 50 miles long, and extending from north to south, about 60 miles west of the Utah boundary (Map: Nevada, F 2). They are a northern continuation of the Ruby Mountains, are well wooded, and are the most rugged range

within the State, several of the peaks reaching a height of from 11,000 to 12,000 feet. They form the parting for most of the streams which flow westward in Nevada. Frémont's Pass is in this range.

EAST INDIA ARMY. The troops in the pay and employment of the East India Company. They were largely natives, with a scattering of European adventurers, liberated convicts, and army deserters. Later a few regiments were raised in England, which since the Act of 1861 reorganizing the Indian army have been a part of the British regular army, under the army numbers of the 105th, 106th, 107th, 108th, and 109th regiments of infantry and the Twenty-first Regiment of Massassars.

Before the British rule in 1857 the army in the pay of the East India Company consisted of about 24,000 British regulars, lent from the English military establishment, but paid for by the company; 18,000 European troops, raised and drilled in England, but the property of the company; 180,000 native and 60,000 native irregular horse—about 240,000 in all. In 1861 the East India army ceased to exist, the Europeans joining the British army, as before stated, and the native troop forming the nucleus of what is now the British Indian native army.

EAST INDIA COMPANY. The name given to trading companies intrusted by various European governments with the monopoly of their East Indies. The most important one was the English Company, the original charter of which was obtained from Queen Elizabeth on Dec. 31, 1600, granting for 15 years the monopoly of trade with all parts of the world not held by friendly European powers between the Cape of Good Hope eastward to the Strait of Magellan. There were originally 125 stockholders, from whom were chosen each year the governor and 24 directors to manage all the business of the company. The original stock was £72,000; indeed, the first voyages of the company were undertaken at the risk of such of the stockholders as would advance the requisite capital. In 1612 it was made a joint-stock company with £400,000 capital. At the beginning of the eighteenth century the stock had increased to three millions, and in 1853 it was valued at six.

At first the venture was esteemed to be of such a precarious nature that the company was aided by exemption from export duties and in other ways. The first voyages, however, were highly successful, and the trade continued to increase, notwithstanding the bitter and often bloody struggles with foreign companies, the wealth of the Orient having attracted other European nations than the English. The Portuguese had a practical monopoly of the trade during the sixteenth century, but they made but sorry traders, being rather concerned with establishing an empire and spreading Catholicism. With them the whole trade was a royal monopoly. When Portugal was united with Spain under Philip II, nearly all its East Indian possessions were lost to the Dutch in the wars of the latter against Spain. The Dutch, who were traders only, looking for immediate returns and being without farsighted plans of future gains and empire, did not maintain their great advantage. In their struggle with the English Company they indeed maintained their establishments in the Spice Islands, Sumatra, Java, Malacca,

and elsewhere, and drove the English away, but they lost their possessions in India. Then came the most serious struggle between the English and the French Company, the latter having been established in 1664. It began in 1745 and was not finally terminated until 1761. Victory fell to the English through the genius of Clive, who was almost matched by the Frenchmen La Bourdonnais and Dupleix. These wars caused the Europeans to mingle in the affairs of the native states, with the result that during the eighteenth century the English Company had become a great territorial power and laid the foundations of the British Empire in India.

As a trading organization, it held for over 200 years the practical monopoly of the trade of Great Britain with the Far East. The most important trade was with India and China, importing tea, pepper, spices, drugs, calicoes, silks, etc. Its chief exports were the precious metals, for which reason the company was from its inception very unpopular at home. According to the current economic doctrine of the day, only that trade should be encouraged which found markets for English goods and brought money into the country, thereby promoting the national welfare. It was urged in 1763 that more money came into England by the sale of Oriental goods than the company could possibly take away—reasoning which experience proved to be correct.

For this and other reasons the stockholders often had difficulty in getting their charter renewed, having usually to pay for it by a loan to the government or some other service, although they usually succeeded in maintaining their monopoly. In 1650 and again in 1655 they absorbed rival companies, which had been incorporated under the Commonwealth and Protectorate. Indeed, in 1653, the experiment of free trade with India was tried, but proved a failure. After the revolution of 1688, which in the Declaration of Rights maintained the right of interlopers to trade, the company experienced great difficulty in obtaining a parliamentary charter in addition to the royal charter they already possessed. Parliament was opposed to monopolies on principle and favored the admission of interlopers to the trade. The company maintained that the interlopers were quite irresponsible and, if unsuccessful in trade, often took reprisals on the natives and embroiled them with the latter. Nevertheless, a new general company, open to all individuals, was established in 1698. After bitter struggles and great confusion in the trade both companies were united by Act of Parliament in 1702. Every member holding over £500 of stock was entitled to from one to four votes, according to his holding, in the general court of proprietors, who elected the governor and a board of 24 directors from among the holders of not less than £2000 of stock. The directors were chosen for four years, six retiring each year.

Meanwhile the increasing political power of the company furnished endless opportunities for corruption among its servants in India and for misrule and oppression of the natives. Its baneful influence in corrupting Parliament was well known. It was quite natural, therefore, that in 1773 a more complete control by the government was established. In 1784 an Act originated by the younger Pitt gave to the King the power of appointing a board of control over the civil and military, but not the commercial, acts of

the company. In 1813 the trade with India was thrown open, the company maintaining its existence as a political body for the government of India only, and in 1833 its last great monopoly, the trade to China, was abolished, the dividends of the company being guaranteed by taxes levied on the India possessions. Its inability to cope with the terrible Indian revolt of 1857 gave Parliament reason for concentrating all its powers in the Imperial government, which guaranteed a 10½ per cent yearly dividend on £6,000,000 of its stock. Henceforth the East India Company continued to exist as an organization for receiving and distributing these dividends only.

The Dutch East India Company was incorporated by the States-General of Holland in 1602, with a capital of about 6,600,000 florins. It was the union of several smaller companies which had been formed in consequence of successful voyages to the Spice Islands, beginning with 1595, when Philip of Spain closed the port of Lisbon to the Dutch. Its monopoly extended from the Cape of Good Hope to the Strait of Magellan, with sovereign rights in whatever territory it might acquire. The first expeditions (1602-05) were very successful and resulted in permission from the native states to use a large number of ports and to build a fortified factory in Java. In 1605 began the 60 years' war with Spain, at the end of which the Dutch Company had despoiled Portugal, which was then united with Spain, of all its East Indian possessions and had supplanted the Portuguese in the Sunda and Molucca islands, Ceylon, the Malabar Coast, Malacca, Japan, and the Cape of Good Hope. As a basis of their power, the Dutch secured vast territorial possessions in the Sunda Islands, especially in Java, Sumatra, and Celebes, and in the Moluccas. They had other stations, but they were for trade only and were unfortified. The most influential founder of the Dutch Indian Empire was Governor Jan Pietersz Coen, who in 1619 established Batavia in Java as its capital. Hither came the ships from all the other stations, a centralization which enabled them to control the trade. In the insular possessions of the company the native governments were left in control, subject only to taxes and to the trade monopoly of the company.

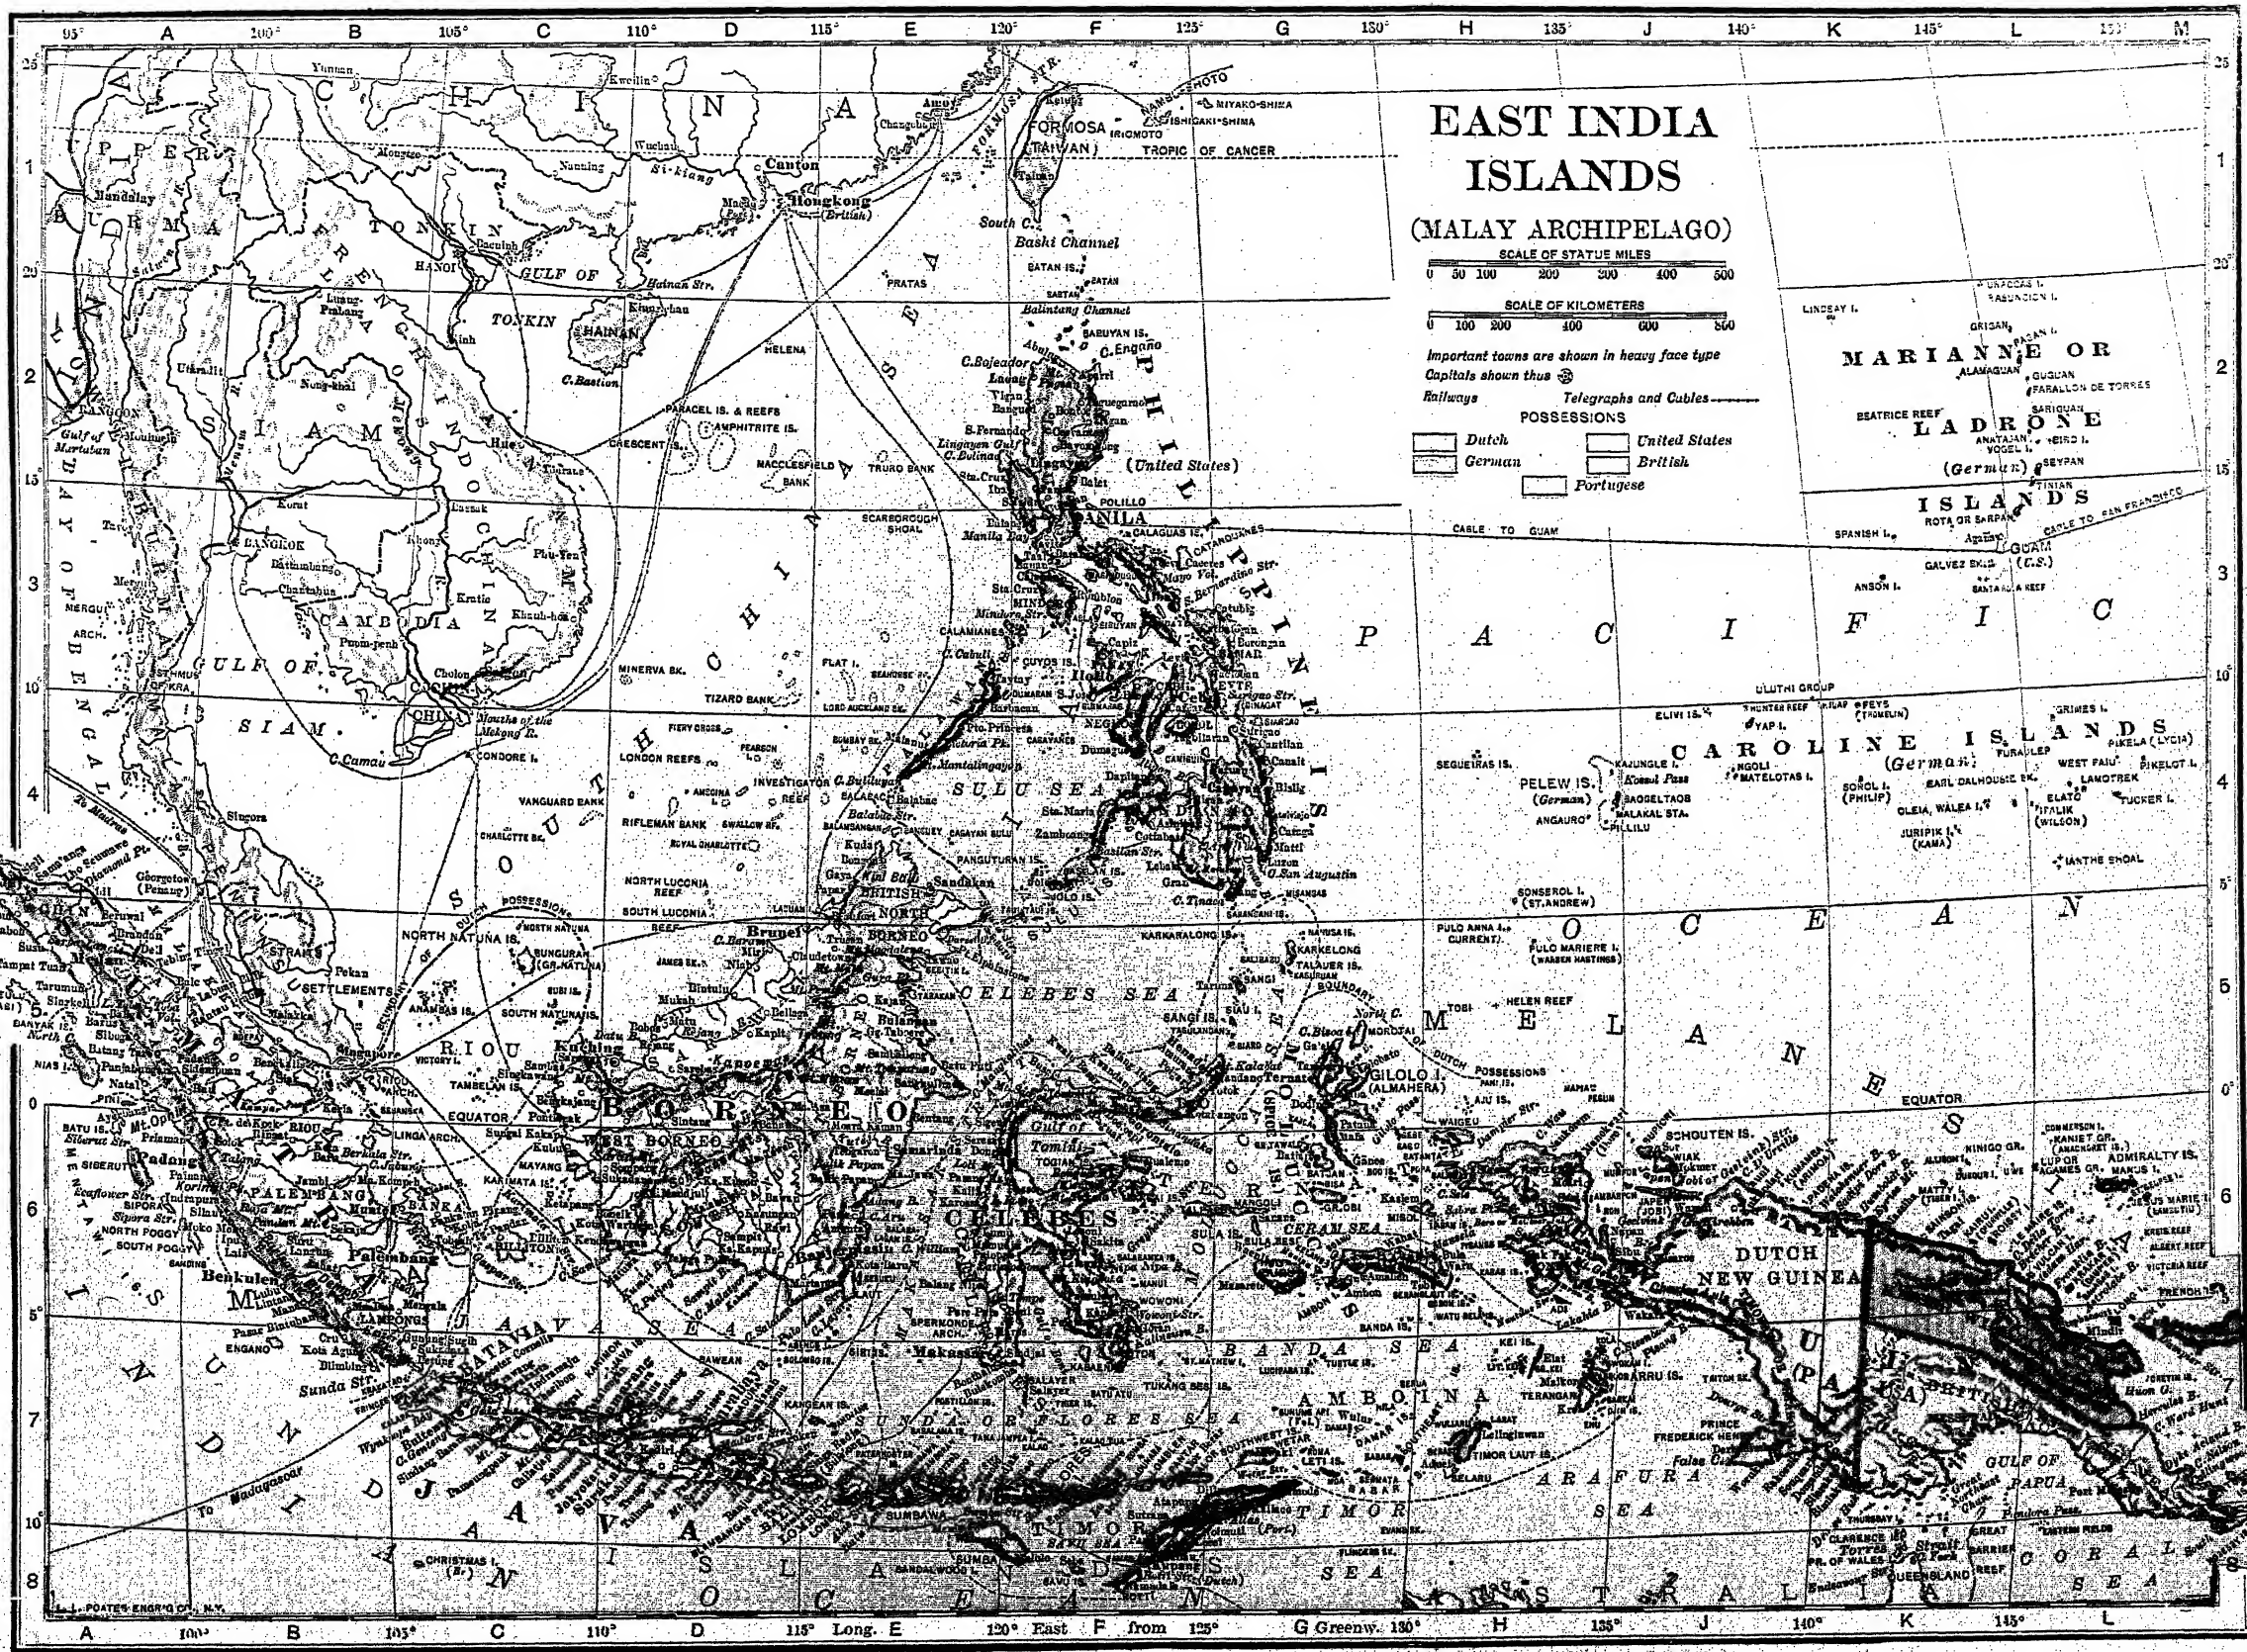

Directed by practical merchants of experience, the company prospered. Between 1602 and 1696 the dividends were never less than 12 and sometimes as high as 63 per cent. The charter was renewed every 20 years, in return for financial concessions made to the state, to which the company in 1696 contributed 8,000,000 florins, in addition to 400,000 florins for the privilege of raising taxes. It was of far greater importance than any other company during this period. But in the eighteenth century came the decline, due to the control of the company by a few rich families, who used it as a means of immediate gain, and to its cruel conduct towards the natives, by which its territorial possessions came into great disorder. No dividends were paid after 1724. When the English attacked its possessions in 1780, on the pretext that Holland was about to join the league of neutrals in favor of America, the Dutch Company was incapable of resistance. It lost practically all of its possessions, and although most of them were returned to Holland by the Treaty of 1815, in the meantime (1798) the company itself had been abolished and its possessions incorporated with those of the state, which also assumed its debts.

The French East India Company was established in 1664, during the reign of Louis XIV, through the instrumentality of Colbert, under the name of *La Compagnie des Indes Orientales*. Its original capital was 6,000,000 livres, afterward increased to 15,000,000, of which the King subscribed 3,000,000. It was founded under favorable conditions, with almost complete sovereignty of the territory it might acquire, and with all possible protection from the French government. It served the political purpose of operating against the powerful Dutch Company, against which, however, it made but little headway. Under the governorship of the Dutchman Caron the first French factory was established at Surat, and successful negotiations were begun with Persia and Indo-China. His successor, Francois Martin, founded Pondicherry in 1676, and under his long and prudent administration, which lasted till 1727, the affairs of the company prospered. In 1687, however, the company lost its privilege of trade with China, and in 1719 it was united with the *Compagnie des Indes Occidentales* and the *Compagnie de la Chine* into the *Compagnie des Indes*.

The united company was one of the schemes of Law, and its stocks shared the fate of his speculations. (See *MISSISSIPPI BUBBLE*.) In 1730 it was deprived of the trade with Africa, in 1731 of the trade with Louisiana, and in 1736 of the coffee trade with America. But the company prospered in India under the able governor Dumas (1735-41), who, by taking advantage of the quarrels among the natives, greatly extended its possessions and influence. Equally successful was his illustrious successor, Dupleix (1741-54), ably supported in military matters by La Bourdonnais (q.v.). Notwithstanding his able conduct of affairs against the English, he was recalled in 1753, and, unsupported by the home government, the colony was unable to maintain itself. (See the account of the *Seven Years' War* given above.) The activity of the company was suspended by royal decree in 1769, and in the following year it turned over its capital, amounting to over 500,000,000 livres, to the King. In 1785 a new company, with commercial privileges only, was established, but it was definitely abolished by the Convention in 1794.

Danish East India Company. After unsuccessful attempts in 1616 and 1634, a Danish company was established in 1729 by King Frederick IV. Unfettered by the trade restrictions under which the other companies labored, it became at the end of the eighteenth century one of the principal trading companies of Europe. Its prosperity declined with the advance of the English Empire in India, and it was ruined in the war between Great Britain and Denmark in 1801. Its possessions, of which Tranquebar and Serampur were the chief, were sold to Great Britain in 1845.

Bibliography. For information concerning the *ENGLISH COMPANY*, consult: *Charters Granted to the East India Company from 1601: Treaties and Grants from the Princes of India from 1756 to 1812* (London, n. d.); *The Law Relating to India and the East India Company* (ib., 1841); Stevens, *Dawn of British Trade to the East Indies* (ib., 1886), consisting of reprints of the minutes of the company's meetings during the early period. The standard work on the subject is J. Bruce, *Annals of the East India Company* (ib., 1810); Sir W. W. Hunter,

History of British India (Oxford, 1899), and J. A. Mills, *History of British India*, ed. by H. H. Wilson (London, 1858), are also valuable. An excellent brief modern account from the economic standpoint is W. Cunningham, *Growth of English Industry and Trade in Modern Times*, pp. 26-29, 125-132, 267-278, 532-570, 593-597 (Cambridge, 1892). Dr. Macpherson, *Annals of Commerce* (London, 1805), is standard. Consult also: W. T. Raynal, *A Philosophical and Political History of the Settlement and Trade in the East and West Indies* (ib., 1777); J. Macpherson, *The History and Management of the East India Company* (ib., 1779); *Letters Received by the East India Company from its Servants in the East* (6 vols., ib., 1902), ed. by Wm. Foster; Beckles, *Ledge and Sward* (ib., 1903); F. P. Robinson, *Trade of the East India Company from 1709 to 1813* (New York, 1912); William Foster, *English Factories in India, 1618-45* (7 vols., Oxford, 1906-13); E. B. Sainsbury, *Calendar of the Court Minutes, 1635-54* (4 vols., ib., 1907-13).

General histories of the company and its career are those of Van Kampen (Haarlem, 1831-33); Meinsma (Delft, 1872-73); Lauts (ib., 1853-66); Terwogt (Hoorn, 1891); Deventer (The Hague, 1886-87); Jonge (ib., 1886-1895).

For information about the FRENCH COMPANY, consult: Castonnet des Fosses, *L'Inde française avant Dupleix* (Paris, 1887); Dufresne de Francheville, *Histoire de la Compagnie des Indes* (ib., 1746); Weber, *La Compagnie française des Indes* (ib., 1904); Grolons, *La Compagnie française des Indes orientales de 1664 considérée comme société de commerce* (ib., 1911).

EAST INDIA HOUSE. The home of the East India Company, on Leadenhall Street, London, removed in 1862. Its noted museum was removed to Fife House, Whitehall, and in 1880 was placed under the management of the South Kensington Museum. Charles Lamb, James Mill, and John Stuart Mill held clerkships in the East India House.

EAST INDIAN DUCK. A variety of domestic duck. See DUCK.

EAST INDIES. The southeastern part of Asia, embracing India and Indo-China and the Malay Archipelago. In this broad sense the term is now used. "East Indies" now usually mean the Malay Archipelago alone. Most of the archipelago belongs to the Netherlands and is called Dutch East Indies. (See accompanying map.) The name "Indies" originated in the fifteenth century, and its meaning was afterward extended to include the newly discovered lands in the New World. Later a distinction was made between the West and East Indies. See DUTCH EAST INDIES; MALAY ARCHIPELAGO.

EASTINGS. See SAILINGS.

EAST JORDAN. A city in Charlevoix Co., Mich., 145 miles by rail northwest of Bay City, on Pine Lake, which has deep-water connection with Lake Michigan, and on the Michigan Central and the Pere Marquette railroads (Map: Michigan, D 3). It is in an agricultural and lumbering region, and has machine and car-repair shops, an iron furnace, saw and lath

mills, flour mills, a creamery, a cooperage, and manufactories of wood alcohol, library tables, brick flooring, chemicals, etc. The city adopted the commission form of government in 1911. It owns its water works. Pop., 1900, 1205; 1910, 2516.

EAST KINGDOM. See AUSTRASIA.

EAST LAKE. Formerly a town in Jefferson Co., Ala., now incorporated into the city of Birmingham (Map: Alabama, C 2). Howard College (Baptist) and the Alabama Boys' Industrial School are here.

EASTLAKE, SIR CHARLES LOCK (1793-1865). An English historical and figure painter and art critic. He was born at Plymouth, Nov. 17, 1793, the youngest son of George Eastlake, solicitor to the Admiralty and judge advocate of Plymouth. He studied in the schools of the Royal Academy in 1809 and also under Haydon. As early as 1810 he attracted attention with "The Raising of Jairus's Daughter." In 1815 Eastlake was in Paris, studying and copying pictures from the Louvre. He was at Plymouth when Napoleon arrived there on board the *Belcophon*; from a boat he made sketches which he used for a portrait of the Emperor. In 1817 he went to Italy and in 1819 to Greece. Afterward he returned to Rome and there spent 14 years. He devoted himself chiefly to landscape painting and landscape with figures of Italian peasantry. He lived principally in Rome until he was elected an Academician in 1830, when he settled in London. In 1823 he sent to the Royal Academy three so-called "banditti" pictures, with views of Rome, and in 1827 "The Spartan Isidas," now in possession of the Duke of Devonshire, attracted much attention. In 1841 Eastlake was appointed secretary to the Royal Commission for decorating the Houses of Parliament, in 1842 librarian to the Royal Academy, and in 1843 keeper of the National Gallery. In 1850 he was knighted and elected president of the Royal Academy, and in 1855 director of the National Gallery. From that time until his death he was chiefly engaged in selecting pictures to be bought by the government for the National Gallery. He died in Pisa, Dec. 14, 1865. Eastlake translated and edited several books on painting, among them Goethe's *Theory of Colors* (1840) and Kugler's *Schools of Painting in Italy* (1842). He also wrote many articles for periodicals, and some books, notably *Materials for the History of Oil Painting* (1847) and *Contributions to the Literature of the Fine Arts* (1848; 2d series, 1870). As a painter, however, he is less important, being a representative of academic eclecticism. Among his principal paintings are "Pilgrims in Sight of Rome" (1828), considered his masterpiece; "Lord Byron's Dream" (1829), in the Tate Gallery, London; "Gaston de Foix" (1838); "Christ Blessing Little Children" (1840); and a series of female heads, artistically his best effort. For his life, consult the *Memoir* by Lady Eastlake (London, 1870); Monkhouse, *Pictures by Sir Charles Eastlake* (ib., 1875).

EASTLAKE, LADY ELIZABETH (RIGBY) (1809-93). An English author, born at Norwich, England. She lived for some time in Germany and at Reval, in Russia, and in 1841 her first book, an account of her residence at the latter place, entitled *A Residence on the Shores of the Baltic*, was published in London. In 1842 an introduction to Lockhart led to her becoming a regular staff contributor to the *Quarterly Review*, a connection which continued for many

years. She married Sir Charles Lock Eastlake, the artist, in 1848, and traveled with him extensively in Italy. Her attack, in the *Quarterly Review* (1848), on *Jane Eyre*, is the least pleasant episode of her literary career. She published *The Jewess*, a novel (1843); *Livonian Tales* (1844); *Music and the Art of Dress* (1852); *Life of John Gibson, R.A., Sculptor* (1870); *Life of Mrs. Grote* (1880); *Five Great Painters* (2 vols., 1883). She translated Waagen's *Treasures of Art in Great Britain* (4 vols., 1854-55) and Brandl's *Samuel Taylor Coleridge and the English Romantic School* (1886), and edited her husband's works (1870) and his edition of Kugler's *Handbook of Painting: Italian Schools* (1874).

EAST LIVERMORE. A town in Androscoggin Co., Me., 23 miles (direct) north of Lewiston, on the Maine Central Railroad, and on the Androscoggin River (Map: Maine, B 4). It is in a rich farming region and has paper mills. The water works are owned by the town. Pop., 1900, 2129; 1910, 2641.

EAST LIVERPOOL. A city in Columbiana Co., Ohio, 44 miles west by north of Pittsburgh, Pa., on the Pennsylvania and the Youngstown and Ohio River railroads, and on the Ohio River (Map: Ohio, J 4). It has a Carnegie library and three parks. Two bridges connect the city with Chester and Newell, W. Va. East Liverpool is the most important centre in the United States for the manufacture of porcelain, including porcelain dinner ware, floor tile, and porcelain electrical supplies. There are also machine shops, steel works, a large sewer-pipe factory, and brickworks. The city has a supply of natural gas. The government, under the Ohio Code of 1902, is vested in a mayor and a board of public service, biennially elected, and a council. The board of public safety is appointed by the executive and council. The water works are the property of the city. East Liverpool was settled as early as 1793 and was incorporated in 1834. Pop., 1900, 16,485; 1910, 20,387; 1914 (U. S. est.), 21,877.

EAST LONDON. A seaport town and popular resort of Cape of Good Hope Province, situated at the mouth of the Buffalo River, on the east coast (Map: Africa, G 8), 666 miles south of Johannesburg by rail. It has a number of banks, a municipal market, two public libraries, and several consular representatives. There is a spacious landing at the mouth of the river, accessible for vessels drawing 22 feet, though the harbor is exposed. The town, being the entrepot for the Transkei, Basutoland, the southern part of Orange Free State, and Johannesburg, is one of the most important ports of Cape Colony, its trade in 1913 amounting to \$67,459,700. The chief article of export is wool. Pop., 1904, 25,220; 1911, 20,867.

EAST LOTHIAN, IOTHIAN. See HADDINGTONSHIRE.

EAST MAIN. A former portion of the Hudson Bay territories, now incorporated as the Ungava district (q.v.), in the Dominion of Canada (Map: Canada, Q 5). The East Main or Slade River crosses its southern section, entering James Bay, the southern extension of Hudson Bay, about lat. 52° 15' N., after a course of 400 miles.

EASTMAN, CHARLES ALEXANDER (OHYESA) (1858-). An American physician, born at Redwood Falls, Minn. His father, "Many Lightnings" (Jacob Eastman), was a full-blooded

Santee Sioux Indian, and his mother, Nancy, was a half-blood Sioux. He graduated from Dartmouth College in 1887 and served in the medical department of Boston University in 1890. From 1890 to 1893 he was government physician at the Pine Ridge Agency, where he had charge of the wounded prisoners at the time of the Ghost Dance Outbreak. He also served as Indian secretary under the International Committee of the Young Men's Christian Association (1894-97), attorney for the Santee Sioux at Washington (1897-1900), and government physician at Crow Creek, S. Dak. (1900-03). In 1903 he received an appointment to revise Sioux family names. He became widely known as a lecturer on Indian history and life. He is author of *Indian Boyhood* (1902); *Red Hunters and the Animal People* (1904); *Old Indian Days* (1907); *Wigwam Evenings* (1909), with his wife (see GOODALE, ELAINE); *The Soul of the Indian* (1911); *Indian Child Life* (1913).

EASTMAN, CHARLES GAMAGE (1816-61). An American editor and poet. He was born at Fryeburg, Oxford Co., Me., and graduated at the University of Vermont in 1837. He founded the *Spirit of the Age*, published at Woodstock (1840), and in 1846 he became the proprietor of the *Montpelier Patriot*, which he edited for nearly 15 years. In 1848 he published a volume of his poems, in which his delineations of the rural life of New England secured for him the title of the "Burns of the Green Mountains."

EASTMAN, ELAINE GOODALE. See GOODALE.
EASTMAN, GEORGE (1854-). An American inventor and capitalist, born at Waterville, N. Y., and educated at Rochester, N. Y., where he thereafter resided. He perfected a process for making sensitive gelatin dry plates and invented a plate-coating machine in 1880. Four years later he patented the first successful rollable film, and in 1888 he perfected the first "Kodak." In 1890 he obtained a patent for the first machine for manufacturing transparent film rolls. He became treasurer and general manager of the Eastman Kodak Company, the manufacturing and distributing plant in Rochester, managing director of the Kodak Company, Ltd., London, England, and president of the Eastman Kodak Company of New Jersey. In 1900 he was made a chevalier of the Legion of Honor. He gave \$225,000 to the Rochester Mechanics Institute in 1900, physical laboratories to the University of Rochester, and in 1912, \$500,000 towards the endowment of the latter institution.

EASTMAN, HARVEY GRIDLEY (1832-78). An American educator, born in Marshall, N. Y. He was the founder in 1855 of a commercial school at St. Louis and in 1859 of the Eastman National Business School at Poughkeepsie, N. Y.

EASTMAN, JOHN ROBERT (1833-1913). An American astronomer, born at Andover, N. H. He graduated from Dartmouth College in 1862, until 1865 was an assistant in the United States Naval Observatory, where (1874-91) he had charge of the meridian-circle work, and was professor of mathematics in the United States Navy (1865-98). Retired in 1898 with the grade of captain, he was in 1906 promoted rear admiral. He observed solar eclipses in various parts of the world, in 1882 had charge of the Transit of Venus party to Cedar Keys, Fla., was the first president (1898) of the Washington Academy of Sciences, and published, besides many reports, *Second Washington Star Cata-*

logue (covering the results of about 80,000 observations made between 1866 and 1891), *Transit Circle Observations of the Sun, Moon, Planets, and Comets* (1903), and a *History of the Town of Andover, N. H., 1751-1906* (1910).

EASTMAN, SETH (1808-75). An American soldier. He was born at Brunswick, Me., and in 1829 graduated at the United States Military Academy and was assigned as lieutenant in the First Infantry. After serving on frontier duty at Forts Crawford (1829) and Snelling (1830) and on topographical duty from 1831 to 1833, he was appointed assistant instructor in drawing at West Point (1833-40). From 1850 to 1857 he was engaged in the Bureau of Indian Affairs as illustrator of the *History, Condition, and Future Prospects of the Indian Tribes of the United States*. He was promoted through successive grades to be a lieutenant colonel of infantry (1861), was retired in 1863, and brevetted brigadier general in 1866. He wrote a *Treatise on Tracing* (1837).

FAST MAUCH CHUNK. A borough in Carbon Co., Pa., 53 miles south by east of Wilkes-Barre, on the Lehigh Valley, the Central of New Jersey, and the Mauch Chunk Switch Back railroads, and on the east bank of the Lehigh River (Map: Pennsylvania, K 5). It is in the anthracite coal field and has silk mills. Pop., 1900, 3458; 1910, 3458.

EAST MOLINE, mō-lēn'. A city in Rock Island Co., Ill., 5 miles east of Moline, on the Mississippi and Rock rivers, and on the Chicago, Milwaukee, and St. Paul, the Chicago, Rock Island, and Pacific, the Davenport, Rock Island, and Northwestern, and the Chicago, Burlington, and Quincy railroads. The industries include manufactures of automobiles, agricultural implements, scales, gas engines, malleable iron goods, sashes and doors, cement blocks, and brick. East Moline was incorporated as a village in 1903 and as a city in 1907. It owns its water works. Pop., 1910, 2665.

EAST NEWARK. A borough in Hudson Co., N. J., adjoining the east bank of the Passaic River and on the Erie Railroad. It is the home of the Clark Thread Company. The borough contains a public library. Pop., 1900, 2500; 1910, 3163.

EASTON, es'ton. A city and the county seat of Talbot Co., Md., 59 miles by rail southeast of Baltimore, on the Baltimore, Chesapeake, and Atlantic, and the Philadelphia, Baltimore, and Washington railroads (Map: Maryland, G 3). It is connected with Baltimore by steamship lines. Easton is the seat of a bishop of the Protestant Episcopal church and contains a hospital. The industrial establishments include foundries and machine shops, flour and lumber mills, canning factories, carriage and wagon works, and furniture and shirt factories. Easton is governed by a mayor and council. The water works, electric-light plant, and sewage system are owned by the city. Pop., 1900, 3074; 1910, 3083.

EASTON. A town, including several villages, in Bristol Co., Mass., 24 miles south of Boston, on the New York, New Haven, and Hartford Railroad (Map: Massachusetts, E 3). It has a public library and some fine public buildings, gifts of the Ames family, showing some of the best work of H. H. Richardson and John Lafarge. There are extensive manufactures of shovels, foundry and machine-shop products, hardware specialties, wire goods, automobiles, lace ma-

chinery, shoes, etc. Pop., 1900, 4837; 1910, 5083.

EASTON. A city and the county seat of Northampton Co., Pa., at the junction of the Delaware and Lehigh rivers, 50 miles (direct) north of York and 77 miles by rail west by York (Map: Pennsylvania, L 5). It is on the Pennsylvania, the Lehigh Valley, the Central of New Jersey, the Lackawanna, and the Lehigh and Hudson River railroads, and is connected by canals with New York, Philadelphia, and the coal regions. The city is near the great cement belt and near slate quarries and coal and iron fields. It has manufactures of drills, compresses, pumps, stoves, pipes and castings, railway supplies, organs, crayons, agricultural implements, blast furnaces, carved and turned wood, textile and woolen goods, silk, hosiery, braces, etc. Easton is the seat of Lafayette College (q.v.), founded in 1832, and contains an academy, preparatory school, school of music, hospital, and a public library. The commission form of government was adopted in 1913. Easton owns and operates its electric-light plant. Pop., 1890, 14,481; 1900, 25,238; 1910, 28,523; 1914 (U. S. est.), 29,882. Easton was laid out in 1750, was incorporated as a borough in 1789, and was chartered as a city in 1887. Here in 1756, 1757, 1758, and 1761 important treaties were made with the Indians, and in 1779 General Sullivan's expedition against the Iroquois was based here. Consult Condit, *The History of Pennsylvania*, 1889).

EASTON, MORTON WILLIAM (1841-). An American philologist. He was born at Hartford, Conn., and, after attending Yale and Columbia, took a supplementary course at the University of Vienna. After occupying the chair of comparative philology at the University of Tennessee for several years, he was appointed to a similar post in the University of Pennsylvania. His writings include: *Observations on the Platform at Persepolis* (1892); *Readings in Gower* (1895); contributions to the *Journal of the American Oriental Society* on phonetics, Sanskrit, Iranian, and kindred subjects; to the *Transactions of the American Philological Association*, the *American Journal of Philology*, and similar publications.

EASTON, NICHOLAS (1593-1675). A Colonial settler of Rhode Island. A tanner by trade, he emigrated from Wales to Massachusetts in 1634, was one of the first settlers of Newbury, Mass., in 1635, and in 1638 built the first English house in Hampton, N. H. He was associated with Anne Hutchinson at Aquidneck in 1638, and in 1639 went to the site of the present Newport, R. I., where also he built the first house. He was President of Providence Plantations in 1648, 1649, and 1650, and again in 1654, served for four years as Deputy Governor, and in 1672-74 was Governor under the second charter.—His son JOHN was Governor from 1690 to 1695 and was the author of a *Narrative of the Causes which Led to King Philip's War*, which was edited by Franklin B. Hough (Albany, 1858).

EAST ORANGE. A city in Essex Co., N. J., adjoining the Erie and the Lackawanna (Map: New Jersey, D 2). It is primarily residential, containing the handsome suburban homes of many New York and Newark business men. East Orange has well-paved and shaded streets and has munic-

ipal playgrounds, an orphan asylum, a woman's club, a fine high-school building, and a large Carnegie library. Its industrial plants include electrical works and manufactories of pharmaceutical supplies, brass and iron castings, and bread. The government is administered by a mayor, elected biennially, and a city council. All municipal officials are appointed by the executive with the consent of the council. The water works are owned by the city. East Orange was part of Orange until 1863, when it was incorporated as a separate township. In 1899 it was chartered as a city. Pop., 1900, 21,506; 1910, 34,371; 1914 (U. S. est.), 39,852. Consult Whittemore, *The Founders and the Builders of the Oranges* (Newark, 1896).

EAST PALESTINE. A village in Columbiana Co., Ohio, 18 miles south of Youngstown, on the Pittsburgh, Fort Wayne, and Chicago Railroad (Map: Ohio, J 4). The industrial establishments include potteries, coal mines, terra-cotta and tile works, machine shops, and a rubber factory. The city owns its water works and electric plant. Pop., 1900, 2,493; 1910, 3,537.

EAST PITTSBURGH. A borough in Allegheny Co., Pa., 3 miles southeast of Pittsburgh, on the Pennsylvania, the Bessemer, and Lake Erie, and the Union railroads. Factories of the Westinghouse electric and machine companies are situated here, and there are manufactories of meters, machines, steel and rails, and furnaces. Adjoining East Pittsburgh is Braddock's Field, the site of the defeat of General Braddock's forces by the French and Indians in 1755. Pop., 1900, 2,883; 1910, 5,615.

EAST POINT. A city in Fulton Co., Ga., 6 miles southwest of Atlanta, on the Central of Georgia and the Atlanta and West Point railroads (Map: Georgia, B 2). It has oil mills, fertilizer factories, saw and planing mills, iron works, cotton mills, and manufactories of saws, wagons, collars, etc. Pop., 1900, 1,315; 1910, 3,682.

EASTPORT. A city and port of entry in Washington Co., Me., 135 miles by rail from Bangor, on Moose Island, in Passamaquoddy Bay, and on the Maine Central Railroad (Map: Maine, F 4). It is the easternmost city in the United States, possesses a deep harbor, and has steamboat communication with important points on the coast. Eastport is the centre of large fishing and sardine-canning interests. The city contains a customhouse and a public library. The government is administered under a charter of 1893, by a mayor, elected annually, and a board of aldermen. Pop., 1900, 5,311; 1910, 4,961. Eastport was permanently settled about 1782. Its trade was severely crippled by the Embargo Act, and the town was for several years, especially during 1807-18, notorious as a smuggling centre. Great Britain had long claimed all the islands in Passamaquoddy Bay, and on July 11, 1814, an English force captured Eastport and held it under strict martial law until June 30, 1818. Consult Kilby, *Eastport and Passamaquoddy: A Collection of Historical and Biographical Sketches* (Eastport, 1888).

EAST PROVIDENCE. A town in Providence Co., R. I., separated from the city of Providence by the Seekonk River, on the New York, New Haven, and Hartford Railroad (Map: Rhode Island, C 2). It has chemical, electrical, and wire works, a shoe-string factory, and a bleachery. The government is vested in a town

council, which elects a majority of administrative officials, others being chosen by popular vote. Town meetings are held annually. Together with the town of Seekonk, Mass., East Providence was once a part of the old town of Rehoboth. It was set off from Seekonk when the Massachusetts-Rhode Island boundary line was fixed, and was incorporated in 1862. Pop., 1890, 8,422; 1900, 12,138; 1910, 15,808; 1914 (U. S. est.), 17,369.

EAST RETFORD, *rēt'fērd.* A municipal borough and market town in the County of Nottingham, England, on the Idle, an affluent of the Trent, 138 miles north-northwest of London (Map: England, F 3). The town has a handsome town hall, corn exchange, and market hall. It owns its gas and water supply (both of which yield profits) and maintains public baths, markets, and slaughterhouses. There are iron foundries and manufactories of paper and India rubber, and a considerable trade in hops is carried on. Pop., 1901, 12,340; 1911, 13,385. Retford appears in Domesday and received its first charter from Edward I.

EAST RIVER. The strait connecting Long Island Sound and upper New York Bay (Map: New York City, E 5). It is also connected on the north, through the Harlem River and Spuyten Duyvil Creek, with the Hudson. It separates the boroughs of Manhattan and the Bronx on the west and north from those of Brooklyn and Queens on the east and south. It is about 15 miles long and varies from less than 1/2 mile to 3 1/2 miles in width. Its principal islands are Blackwell's, Ward's, Randall's, Riker's, and North Brother, containing city institutions. A channel between Ward's Island and Long Island, in what is known as Hell Gate, has been made navigable by blasting. The famous Brooklyn Bridge, and the Williamsburg, Queensboro, and Manhattan bridges cross the river.

EAST RUTHERFORD. A borough in Bergen Co., N. J., 9 miles from Jersey City, on the Erie Railroad (Map: New Jersey, D 2). It is essentially a residential place for New York business men, and contains a public library. The chief industrial establishments are extensive cotton and linen bleaching works, a steam boiler factory, and a manufactory of glass mirrors. Pop., 1900, 26,401; 1910, 42,751.

EAST ST. LOUIS. A city in St. Clair Co., Ill., on the Mississippi River, connected by several bridges with St. Louis, Mo., and entered by 20 lines of railroad (Map: Illinois, B 5). East St. Louis is an important manufacturing centre, its industrial interests being promoted by valuable coal deposits in the vicinity. It has manufactories of malleable iron, glass, frogs and switches, aluminum, white lead, paint, bridges, roofing paper, car trucks, car springs, forgings, locomotives, pneumatic tools, and silica, a rolling mill, foundries, a fertilizer plant, grain elevators, baking-powder factories, and flouring mills. There are also a large horse and mule market, alfalfa stock feed, and pork and dressed-beef packing industries. The city contains several parks, and its city hall, high school, and the public library occupy fine buildings. East St. Louis was incorporated as a town in 1861 and was chartered as a city in 1865. It is a progressive municipality, having expended in the last decade more than \$7,000,000 in street and other public improvements, principally for drainage and flood protection. The government is administered by a mayor, elected biennially,

and a city council, of which the executive is a member. The city treasurer, city attorney, assessor, city clerk, justices of the peace, and city court judges are elected by the people. East St. Louis has had rapid growth, its population having increased from 5644 in 1870 to 21,111 in 1900; to 58,547 in 1910; and to 69,502 (U. S. est.) in 1914.

EAST STONEHOUSE. A town in Devonshire, England, forming, with Plymouth (q.v.) and Devonport (q.v.), the aggregation styled "The Three Towns." Pop., 1901, 15,111; 1911, 13,754.

EAST STROUDSBURG. A borough in Monroe Co., Pa., 32 miles north of Easton, on the Delaware, Lackawanna, and Western, the Delaware Valley, the New York, Susquehanna, and Western, and the Wilkes-Barre and Eastern railroads. It is situated in a picturesque region at the foot of the Pocono Mountains, is a popular summer resort, and contains a State normal school. The chief industrial establishments are boiler works, glass factories, silk mills, brass works, and a piano-stool factory. The borough owns its water works. Pop., 1900, 2918; 1910, 3330.

EAST SYRACUSE. A village in Onondaga Co., N. Y., 5 miles north of Syracuse, on the New York Central and the Hudson River railroads, and on the Erie Canal (Map: New York, D 4). It has large freight yards of the New York Central system and a silverware factory. The village owns its water works. Pop., 1900, 2509; 1910, 3274.

EAST THICKLEY. See SHILDON AND EAST THICKLEY.

EASTWARD HO! A comedy by Marston, Chapman, and Jonson.

EASTWICK, EDWARD BACKHOUSE (1814-83). An English diplomatist and Orientalist. He was educated at Merton College, Oxford. In 1845 he was appointed professor of Hindustani at the East India Company's College of Haileybury and in 1859 assistant political secretary in the India Office. From 1860 to 1863 he was Secretary of Legation at the court of Persia, in 1864 and 1867 was a commissioner for the negotiation of a Venezuelan loan, and in 1866 was appointed private secretary to Lord Cranborne, the Secretary of State for India. In 1868-74 he represented Falmouth and Penryn as a Conservative in the House of Commons. His publications include translations of (1852) the *Gulistān*, or 'Rose Garden,' of Sādi, and (1854; republished in Dole and Walker's *Flowers from the Persian Poets*, 1901) the *Anvār-i Suhaili*, with a *Concise Grammar of Hindustani* (1847, 1858); a translation of Bopp's *Comparative Grammar* (1856); a *Handbook for India* (1859, "Murray's Handbooks Series"); *Journal of a Diplomat's Three Years' Residence in Persia* (2 vols., 1864); *Venezuela: or, Sketches of Life in a South American Republic* (1864; 2d ed., 1868; first published in Dickens's *All the Year Round*); *Lord Lytton and the Afghan War* (1879); and his last work, entitled *Kaisar-namah-i-Hind*, 'The Lay of the Empress' (2 vols., 1878-82).

EAST WINDOW. In many English cathedrals, and in a few Cistercian churches on the Continent having square east ends, this end is occupied by a group of windows (Ely, Laon) or by a single large traceried window (Lincoln, Exeter, York, Gloucester). The east window of Gloucester is one of the largest traceried windows in Europe.

EAST WINDSOR. A town in Hartford Co., Conn., 11 miles northeast of Hartford, on the New York, New Haven, and Hartford Railroad (Map: Connecticut, E 2). It contains two libraries and has woolen mills, a silk factory, distilleries, and tobacco warehouses. Pop., 1900, 3155; 1910, 3362.

EAST YOUNGSTOWN. A village in Mahoning Co., Ohio, 4 miles east of Youngstown, on the Baltimore and Ohio Railroad, and on the Mahoning River (Map: Ohio, J 3). The chief industry is the manufacture of iron. Pop., 1910, 4972.

EASY, SIR CHARLES. The title character in Gibber's *Careless Husband*. His tendency towards indolent vice is checked and cured by the sense and tact of an amiable wife.

EASY, MIDSHIPMAN. See MIDSHIPMAN EASY.

EATON, ETON. A village and the county seat of Preble Co., Ohio, 58 miles north by northwest of Cincinnati, on the P. & O. Cincinnati, Chicago, and St. Louis R.R. (Map: Ohio, A 6). It is the centre of a fertile agricultural region and has manufactories of cigars, gloves, cement, etc. There are many noted springs in the village and the village contains a public library and municipal water works. It was here that Little Turtle made his last stand against the whites, under John Adair, who was afterward elected Governor of Ohio. Pop., 1900, 3155; 1910, 3187.

EATON, AMOS (1776-1842). An American scientist, born in Chatham, N. Y. Graduating from Williams College in 1799, he was admitted to the bar and began the practice of law and civil engineering at Catskill, N. Y. He gave much time to study of the natural sciences, including chemistry, mineralogy, and geology, and in 1820 he was engaged by Stephen van Rensselaer to make a geological and agricultural survey of Albany and Rensselaer counties, one of the first of such undertakings in this country. He afterward made a geological survey of the region along the Erie Canal, from which was constructed a profile section of the rock formations from the Atlantic Ocean across Massachusetts and New York to Lake Erie. In 1824 he became senior professor of the Rensselaer School of Science in Troy, now the Rensselaer Polytechnic Institute. His best-known works are: *An Index to the Geology of the Northern States* (1818); *A Manual of Botany of North America* (1833); *Geological Note Book* (1841).

EATON, AMOS BEEBE (1806-77). An American soldier. He was born at Catskill, N. Y., graduated at West Point, and was assigned as lieutenant of Fourth Infantry in 1826. After having served in various garrisons, especially on the northern frontier, he was transferred in 1838 to the Department of Subsistence, and served as commissary. In the Mexican War he was chief commissary of subsistence under Gen. Zachary Taylor, receiving the brevet of major in 1847. During the Civil War he was purchasing commissary at New York City for the armies in the field and in 1864 was appointed commissary general of subsistence at Washington. He rose to the regular rank of brigadier general and in 1865 was brevetted major general. He was retired from active service in 1874.

EATON, ARTHUR WENTWORTH HAMILTON (*1859-). A Canadian poet, essayist, and critic. He was born in Kentville, Nova Scotia,

and was educated at Dalhousie University and at Harvard, where he graduated in 1880. He studied for the ministry of the Protestant Episcopal church, was ordained priest in 1885, and was for a short time rector of a parish at Chestnut Hill, Boston; but he afterward became head of the Department in the Cutler School. His publications include: *The Heart of the Creeds* (1888); *Acadian Legends and Lyrics* (1889); *The Church of England in Nova Scotia* (1891); *Tales of a Garrison Town*, with C. L. Betts (1892); *Acadian Ballads* (1905); *The Lotus of the Nile and Other Poems* (1907); *The History of King's County, N. S.* (1910).

EATON, CHARLES WARREN (1857-). An American landscape painter. He was born in Albany, N. Y., and studied at the National Academy of Design and at the Art Students' League, New York. His canvases, usually evening effects in oil or water color, have often a poetic charm and are truthful in drawing, solid in handling, and softly harmonious in color. Among his landscapes are "The Forest"; "October's Tints"; and "Connecticut Pines" (1910, Brooklyn Museum); "Gray Dunes" and "Forest Lands" (1911); "The Valley of Sunset" and "Among the Dunes" (1912); "The Silent Woods" and "The Pines" (1913); "Gathering Mists" (National Gallery, Washington); and "Dunes at Knocks, Belgium" (Cincinnati Museum). In 1904 he received the Inness gold medal at the National Academy of Design and in 1906 a gold medal at the Paris Salon.

EATON, DANIEL CADY (1834-95). An American botanist. He was born at Fort Gratiot, Mich., studied at Yale and Harvard, and was professor of botany at Yale from 1864 until his death. He contributed to *Gray's Manual* and to Chapman's *Flora of the Southern States* the parts relating to ferns and published *The Ferns of North America* (2 vols., 1878-79).

EATON, DORMAN BRIDGMAN (1823-99). An American lawyer and civil-service reformer. He was born in Hardwick, Vt., was educated at the University of Vermont and the Harvard Law School, and began the practice of law in New York in 1850. In 1866 he drafted the law establishing the Board of Health for New York City and also that creating the municipal police courts. Upon the establishment of the first Civil Service Commission in 1873, he was appointed one of the commissioners by President Grant. He drafted the National Civil Service Act (the Pendleton Act), which became a law in 1883, and was appointed by President Arthur a member of the new commission. He resigned in 1885, but was reappointed by President Cleveland and served until 1886. He published: *Civil Government in Great Britain* (1880); *The Independent Movement in New York* (1880); *The Term and Tenure of Office* (1882); *The Problem of Police Legislation* (1895); *The Government of Municipalities* (1899).

EATON, EDWARD DWIGHT (1851-). An American clergyman and college president, born at Lancaster, Wis. He graduated from Beloit College in 1872 and from Yale Divinity School in 1875 and also studied at Leipzig and Heidelberg. Ordained to the Congregational ministry in 1876, he served the First Church, Oak Park, Ill., from 1879 to 1886; thereafter, except for two years (1905-07) as pastor at St. Johnsbury, Vt., he was president of Beloit

(Wis.) College. He was delegated to inspect Chinese missions in China in 1898, lectured at Andover (Mass.) Theological Seminary in 1904 and at Bangor Theological Seminary in 1906, after 1910 was vice president of the American Board of Commissioners for Foreign Missions, and in 1911 became vice president of the North Central Association of Colleges and Secondary Schools.

EATON JOHN (1829-1906). An American educator and Civil War veteran, born at Thetford, Vt. He graduated at Dartmouth College in 1854, studied at Andover Theological Seminary, and was ordained in 1862 to the Presbyterian ministry. In 1862 General Grant made him superintendent of contrabands, and soon after he became general superintendent of refugees for Mississippi, Arkansas, western Tennessee, and northern Louisiana. In 1863 he was made colonel of the Sixty-third Regiment of Colored Infantry, and in 1865 he was advanced to brevet brigadier general. He reorganized the Bureau of Refugees, Freedmen, and Abandoned Lands, after which he edited the *Memphis (Tenn.) Post* in 1866-67, and in 1867-69 was State superintendent of public instruction in Tennessee. He was appointed United States Commissioner of Education in 1871 and served with great efficiency. In 1886-91 he was president of Marietta College. In 1895 he was appointed president of Sheldon Jackson College at Salt Lake City, and in 1898 he became inspector of education in Porto Rico. His educational writings dealt largely with the education of freedmen and also included a history of Thetford Academy.

EATON, JOHN HENRY (1790-1856). An American legislator. He was born in Tennessee and after studying law devoted himself to practice at the bar in Nashville. In 1829 he married Peggy O'Neill. (See EATON, MARGARET.) He was Secretary of War from 1829 to 1831 and Governor of Florida in 1834-36. In 1836-40 he was Minister to Spain. He wrote a *Life of Andrew Jackson* (1824), a campaign biography.

EATON, MARGARET (O'NEILL), best known as PEGGY O'NEILL (c.1796-1879). The wife of J. H. Eaton (q.v.), Secretary of War under President Jackson. She was the daughter of a Washington tavern keeper and noted for her beauty and wit. About 1823 she married a man named Timberlake, a purser in the United States navy, who in 1828 committed suicide while on duty in the Mediterranean. In January, 1829, she was married to Maj. J. H. Eaton, who soon afterward entered President Jackson's cabinet as Secretary of War. Various charges were brought against her in connection with her alleged conduct towards Major Eaton himself while she was still Mrs. Timberlake. On this account the wives of other cabinet members and Washington society generally refused to recognize her. Jackson, an old friend of both Mr. and Mrs. Eaton, endeavored to break down the opposition against her and even seems to have threatened to remove several of the secretaries should their wives remain obdurate; but his efforts met with little success, and partly for this reason Jackson effected an almost complete reorganization of his cabinet. Politically the incident was chiefly significant from the fact that it helped to strengthen the friendship between Jackson and Van Buren, who had ostentatiously befriended Mrs. Eaton,

and to alienate Jackson and Calhoun, then Vice President, whose wife had persistently refused to recognize Mrs. Eaton socially, and thus to assure the nomination of the former in preference to the latter for the presidency by the Democratic party in 1836. In later years Mrs. Eaton was very popular in the society of Madrid. Her husband was Minister of the United States to Spain. Some time after the death of her husband (1856) she married a young Italian dancing master, Antonio Buchignani, then only about 20 years old, from whom she was divorced after he had squandered much of her property. Consult Parton, *Life of Andrew Jackson*, vol. iii (New York, 1860); and an article "Margaret O'Neill Eaton," in the *International Review*, vol. viii (ib., 1880); Buell, *History of Andrew Jackson* (2 vols., New York, 1904); Bassett, *Life of Andrew Jackson* (2 vols., New York, 1911).

EATON, THEOPHILUS (c.1591-1658). An English merchant, one of the founders and the first Governor of the Colony of New Haven. He was born at Stony Stratford, Buckinghamshire, England, the son of a minister; became a prosperous merchant; was chosen deputy governor of the East Land Company, and lived for several years in Denmark as an agent of Charles I. After his return he settled in London, where he was a member of the Puritan congregation of the Rev. John Davenport (q.v.), and in 1637 accompanied his pastor to Massachusetts, of whose charter he had been one of the original patentees. Late in the same year he selected a site for a new settlement, and early in 1638 he and Davenport with a small number of followers founded the town and Colony of New Haven (q.v.). In October, 1639, a government was regularly organized and Eaton was chosen chief magistrate, to which position he was annually re-elected until his death. He was one of the organizers of the New England Confederation in 1643 and drew up (1655), with the aid of Davenport, the code of laws which have become known as the Connecticut Blue Laws. Consult Moore, "Memoir of Theophilus Eaton," in *Collections of the New York Historical Society*, 2d series, vol. ii (New York, 1849), and a sketch in Mather's *Magnalia*, vol. i (London, 1702).

EATON, WILLIAM (1764-1811). An American adventurer, prominent in the war between the United States and Tripoli. He was born in Woodstock, Conn., ran away from home at 16, joined the army and served until 1783, and graduated at Dartmouth in 1790. In 1792 he rejoined the army as a captain and served successively against the Shawnees in Ohio and the Seminoles in Georgia until 1797, when he was appointed American Consul in Tunis. On the outbreak of the Tripolitan War in 1801 he arranged with Hamet, the rightful Pasha of Tripoli, for a combined land and naval attack upon Tripoli; but he was unable to obtain the cooperation of the American naval officers. He then returned to the United States in 1803, and in April, 1804, was appointed Naval Agent of the United States for the Barbary Powers. Late in the same year he returned to northern Africa and raised a force of 500 men, chiefly Arabs and Greeks, with which in March, 1805, he set out across the Libyan Desert for Derne, the second city in importance in the Tripolitan Regency. This place was captured by storm on April 27 and was held against three subse-

quent attacks on the part of the Arabs. Soon afterward, however, Tobias Lear, the United States Consul General at Algiers, and Commodore Rodgers, commander of the United States fleet before Tripoli, concluded with the usurping Pasha, Yussuf, a treaty which provided, among other things, for the immediate evacuation of Derne, and Eaton was thus forced to give up his cherished scheme of restoring Hamet and obtaining more favorable terms for the United States government. He accordingly returned to America in the fall of 1805. His last years were spent in Brimfield, Mass., which town he represented for one term in the Legislature. Consult: *The Life of the Late General William Eaton* (Brookfield, Mass., 1813); Felton, "Life of William Eaton," in Sparks's *Library of American Biography*, vol. ix (Boston, 1838); and the brief sketch in Adams's *History of the United States from 1801 to 1817*, vol. ii (New York, 1889-91).

EATON, WYATT (1849-96). An American portrait and figure painter. He was born at Phillipsburg, Quebec, of American parentage, but came early to New York and studied in the National Academy of Design and afterward under Gérôme at the Ecole des Beaux-Arts, Paris. He also spent some time at Barbizon, where he associated with and was strongly influenced by Millet. Eaton belongs to no especial group of painters, but sought inspiration rather from the old masters. The chief characteristics of his art are delicacy of tone and color, grace, and sincerity of conception. His most notable works are his portraits, in which he admirably expresses the spiritual personality of the sitter. His rendering of the hands is especially good. The series of American poets, engraved by Timothy Cole for the *Century Magazine*, established his reputation in this country. Since then the portraits of Cole himself as the "Man with the Violin," and Mrs. R. W. Gilder, exhibited at the Paris Exposition of 1889, have made his reputation international. Other fine portraits are those of W. C. McDonald and Hon. Archie Gordon (1895). He was the first secretary and one of the founders of the Society of American Artists and for some years its president. Among his subject pictures are "Harvesters at Rest" (1876, Smith College); "Reverie"; and "Harvest Scene" (Montreal Gallery).

EATON HALL. One of the famous show-places of England, the residence of the Duke of Westminster, the richest peer in England, near Chester. The hall, a fine specimen of Neo-Gothic architecture, is purely modern, erected in 1870-79 by the architect Waterhouse. A well-timbered deer park surrounds it, and gardens and terraces of much beauty are open to the visitor. This park is extensive, the mansion being nearly 3 miles from the lodge gates.

EATONTON. A city and the county seat of Putnam Co., Ga., 59 miles by rail north by northeast of Macon, on the Central of Georgia Railroad, and on the Oconee River (Map: Georgia, C 2). It is in an agricultural, fruit and cotton growing, and dairying country, has cotton factories, and carries on an extensive trade in peaches and plums. The water works and sewage system are owned by the city. Joel Chandler Harris, author of the famous Uncle Remus stories, was born here. Pop., 1900, 1823; 1910, 2036.

EAU CÉLESTE, ô sâ'lest'. See FUNGIOMÉ.

EAU CLAIRE, ô klâr. A city and the

county seat of Eau Claire Co., Wis., 89 miles east of St. Paul, Minn., at the junction of the Eau Claire and Chippewa rivers, on the Minneapolis, St. Paul, and Sault Ste. Marie, the Chicago, Milwaukee, and St. Paul, and the Chicago and Northwestern railroads (Map: Wisconsin, B 4). It is the leading commercial centre of this part of the State, is at the head of navigation on the Chippewa, and has good water power in both rivers. Eau Claire is the outlet of the Chippewa lumber district, and its manufactures of lumber are extensive. There are also foundries, a large paper mill, steel and iron works, breweries, canneries, and manufacturing of furniture, refrigerators, boxes, harness, sashes and doors, and shoes. The city has a Carnegie library, four public parks, fine school buildings, a tuberculosis sanatorium, and the Sacred Heart (Roman Catholic) and the Norwegian Lutheran hospitals. The water works are owned by the municipality. Eau Claire adopted the commission form of government in April, 1910, being the first city in the State to do so. Pop., 1900, 17,517; 1910, 18,310; 1914 (U. S. est.), 18,647.

EAU CRÉOLE, *ô krá'ôl'*. A very fine liqueur, made in Martinique, by distilling the flowers of the mamee apple (*Mammea americana*) with spirit of wine.

EAU DE COLOGNE, *dê kô-lôn'* (Fr., Cologne water). A perfume invented in northern Italy by one of the Farina family, who subsequently settled in Cologne. It is now made by a number of persons bearing the original patronymic, who are residents of Cologne, as well as by perfume makers all over the world. It consists essentially of pure distilled alcohol with various aromatic oils so blended as to yield a refreshing and grateful odor. Various formulas have been given for the original perfume, and among these is the following, published in the journal of the *Nor* Apothecaries' Association: Dissolve 2 ounces of purified benzoin, 4 ounces of oil of lavender, and 2 ounces of oil of rosemary in 9 gallons of 95 per cent alcohol; to this solution add successively of the oils of neroli, neroli petit-grain, and lemon, each 10% ounces, and of the oils of sweet orange peel, limes, and bergamot, each 20% ounces, together with tincture of rose-geranium flowers, sufficient to suit the taste; macerate for several weeks and then bottle. An excellent imitation is made by taking 6 gallons of 95 per cent alcohol, oil of orange and oil of citron each 5 ounces, oil of neroli 4 ounces, oil of rosemary and oil of bergamot each 2 ounces: mix by stirring, and allow to stand until the solution is complete. It is claimed that the best foreign eaux de Cologne are obtained by distillation, the purpose of which is to secure a perfect blending of the perfumes, but in the United States the same result is generally accomplished by allowing the mixture to stand until the desired effect is obtained.

EAU DE JAVELLE, *zhâ'vêl'* (from *Javelle*, near Paris), or **JAVELLE WATER**. A solution of hypochlorite of potash, which is used to remove stains from linen or muslin and from white marble. Practically it is adulterated with bicarbonate of potash. It is poisonous.

EAUX-BONNES, *ô'bûn'*. A watering place in the Department of Basses-Pyrénées, France, 2455 feet above sea level, 20 miles south-southeast of Oloron (Map: France, S. 1 D 6). It is picturesquely situated in a narrow gorge at the

junction of two mountain streams. There are seven hot sulphur springs, used mainly for drinking, and considered of special efficacy for throat diseases and tuberculosis. The place contains a number of fine hotels and is visited annually by about 6000 guests. Permanent population, 1901, 768; 1911, 622. A short distance away is Eaux-Chaudes, with sulphur springs.

EAUX-CHAUDES, *shod'*. See **EAUX-BONNES**.

EAVESDROPPING, or **EAVESDRIP**. In the law of real property, the right to permit rain-water falling upon one's roof to drop from the eaves upon the adjoining land of another. This is not a natural right inhering in lands, like the right of lateral support, but is an easement, which may, like the easement of ancient lights, be acquired by prescription or immemorial user or by grant. It is a variety of the easement of drainage. The right is not lost by changes in the roof or in the height of the house to which it attaches, so long as the drip from the eaves is not thereby substantially increased or otherwise varied. It was recognized at the Roman law as the *urban stillicidium*. See **DRAINAGE**; **EASEMENT**; **SERVITUDE**.

The term "eavesdropping" is also used in a derivative sense in the criminal law of England and the United States to denote a crime of nuisance, punishable as a misdemeanor (q.v.). It consists in secretly loitering about a building with intent to overhear or see what is going on inside and to repeat and publish it to the annoyance, vexation, or injury of others. See the authorities referred to under **CRIMINAL LAW** and the statutes of the several States.

EAVES SWALLOW, **CLIFF SWALLOW**, or **REPUBLICAN SWALLOW**. See **BARN SWALLOW**.

EBAL, *ê'bâl*, and **GERIZIM**, *gêr'i-zim*. Two mountains of Palestine significant in Hebrew tradition in connection with the blessing and cursing of the people (Deut. xi. 29, xxvii. 11-26; Josh. viii. 33-34). They are situated in central Samaria, separated by a narrow valley about 600 feet wide, in which stands the town of Nablus (Neapolis), which is still the metropolis of the Samaritans (Map: Palestine, C 3). They rise to an elevation of 3077 feet and 2849 feet respectively and are known at the present day as *Jebel Suleimiyeh* and *Jebel el-Tur*. The Samaritans erected a temple on Mount Gerizim, probably in the fourth century B.C. It was destroyed by John Hyrcanus in 129 B.C., but the mountain continued to be held sacred. A rivalry between the Jerusalem and the Samaritan cults is a feature of Jewish history and continues to the days of Jesus. The Masoretic text of Deut. xxvii. 4-8 is thought by many to reflect this controversy. The Hebrew text preserved by the Jews enjoins the building of an altar to Yahweh on Mount Ebal and the placing there of large stones inscribed with the law. This injunction, according to the Hebrew text preserved by the Samaritans, refers to Gerizim. Two explanations of the discrepancy are possible. Either the Jewish text is correct and the Samaritan an intentional alteration to justify the building of the temple on Gerizim, or the Samaritan is correct and the Jewish an early change to deprive this temple of its scriptural support. The former view is generally held by modern scholars, but there is much to be said in favor of the latter. If the law which the Samaritans recognized ordained

the construction of a sanctuary on Mount Ebal, it is difficult to see why they should deliberately have chosen the other mountain; while it is quite apparent why the mention of Gerizim as a spot divinely selected for a sanctuary in a book that never refers to Jerusalem by name should have caused a Jewish scribe to correct it as an error. In either case the injunction is singularly out of harmony with the centralizing tendency of the code and seems to point to a firmly rooted tradition. It was to Gerizim and the controversy between Jews and Samaritans concerning its sanctity that the "woman of Samaria" referred in her conversation with Jesus (John iv. 20, 21). The Samaritans claim that Gerizim was the scene of the attempted sacrifice of Isaac (Gen. xxii), and on this mount they still perform the yearly paschal sacrifice. See SAMARITANS.

EBB. See **TIDE**.

EBBON, ɛb'bon' (775-851). A French archbishop. He was the foster brother of Louis le Débonnaire, son of Charlemagne. He was created Archbishop of Rheims. He made three voyages to Denmark and helped to establish Christianity there. When Lothaire revolted against his father, the Archbishop took his part. Upon the King's return to power Ebbon fell into disgrace, and it was not until Lothaire became Emperor that he attempted to regain his bishopric. The Pope refused to reinstate him, and he took refuge with Louis of Bavaria and was made by him Bishop of Hildesheim in Saxony.

EBBW VALE, ɛb'vāl. An urban district of Monmouthshire, England, about 9 miles west-southwest of Abergavenny. It is situated near the source of the Ebbw River, in a mountain wilderness of about 1000 feet altitude. The district produces much iron and steel. Pop., 1901, 20,994; 1911, 30,559.

EBE, ɛ'be, **GUSTAV** (1834-). A German architect, born at Halberstadt. He studied in Berlin and then traveled in France and Italy. In company with Julius Benda, with whom he was associated in Berlin, he executed plans for the Vienna Rathaus, which obtained the first prize in competition, but was not executed. He was later associated in Berlin, where he designed numerous structures, including the Tiele-Winckler Palace, the headquarters of the Spanish embassy and the Apollo Theatre. He is also the author of a work on art, *Die Spätrenaissance* (1886), a history of European art from the middle of the sixteenth century to the end of the eighteenth; *Die Schmuckformen der Denkmalsbauten aus allen Stilepochen seit der griechischen Antike* (8 vols., 1893-97); *Der deutsche Cicerone: Führer durch die Kunstschatze der Länder deutscher Zunge* (4 vols., 1897-1901); *Architektonische Raumlehre* (2 vols., 1900-01); *August Orth* (1904).

EBEL, ɛ'bel, **HERMANN WILHELM** (1820-75). A German Celtic scholar. He was born in Berlin, was educated at Halle, and was a member of the philological faculty of the Berlin University from 1872 to 1875. He was the foremost authority on Celtic philology in Germany, and his researches on the grammatical construction and lexicography of Irish, Manx, Welsh, Cornish, Breton, and ancient Gaelic gave him a permanent place in the field of philology. Besides his principal work, a new and improved edition of Zeuss's *Grammatica Celtica* (1871), he published *Lehnwörter der deutschen Sprache* (1856); *De Verbi Britannici Futuro ac Con-*

unctio (1866: partly translated into English by W. K. Sullivan under the title *Celtic Studies*); *De Zeusi Curis Positis in Grammatica Celtica* (1869).

EBEL, JOHANNES WILHELM (1784-1861). A German Protestant clergyman, born at Passenheim, East Prussia. As pastor at Königsberg, he became the founder of a mystic and theological society which counted among its members many representatives of the nobility. Accused of gross immorality caused a judicial investigation of the society, with the result that he and its organizer removed from office (1839). A subsequent investigation, however, showed that the charges of secret vice, disturbance of domestic peace, and pious fraud brought against the members of the association were not proved. Consult Mombert, *Faith Victorious: Being an Account of the Life and Times of Dr. Johannes Ebel* (London, 1882).

EBEL, JOHANN GOTTFRIED (1764-1830). A German writer on geography, born at Züllichau, Prussian Silesia, and educated at the University of Frankfurt-on-the-Oder. His translation of the works of Sieyès, and his close association with certain revolutionary leaders of France, made him unpopular with the authorities of Frankfurt-on-the-Main, and in 1796 he was banished from that city, where he had begun a medical practice. He subsequently lived in Paris and in Zurich, where his services in behalf of the maintenance of the Swiss Republic, which was endangered by the prevailing political conditions, were rewarded by an offer of citizenship on the part of the municipality of Zurich, in which city he spent the last years of his life. His principal works are the following: *Anleitung auf die nützlichste Art die Schweiz zu bereisen* (2 vols., 1793; 8th ed., 1842); *Geographie der Gebirgs-völker der Schweiz*; *Ueber den Bau der Erde in den Alpengebirgen* (2 vols., 1808). Consult Escher, *Johann Gottfried Ebel* (Trogen, 1835).

EBELING, ɛ'be-ling, **ADOLF** (1827-96). A German author, born in Hamburg. He studied at the University of Heidelberg and became a professor in the Imperial School of Commerce in Paris. In 1870 he returned to Germany and edited for a time the Düsseldorf *Deutsches Künstleralbum*. From 1874 to 1878 he was a professor in the military school at Cairo. His publications include: *Bruchstücke aus der Beschreibung einer Reise nach Brasilien* (1849); *Bilder aus Kairo* (1878); *Memorien über Napoleon I und seinen Hof* (4 vols., 1880-87); *Napoleon III und sein Hof* (1891-93).

EBELING, CHRISTOPHER DANIEL (1741-1817). A German scholar, born in Hildesheim. He early devoted himself to geographical studies. The Congress of the United States gave him a vote of thanks for his great work, *The History and Geography of North America* (5 vols., Hamburg, 1794-1816). While preparing this work, he made a collection of about 4000 books and 10,000 maps, which was purchased in 1818 by Israel Thorndike and presented to Harvard University.

EBENEZER (Heb., *Eben-ha'ezzer*, the stone of help). The name of a place marked by a monumental stone set up by Samuel in recognition of divine assistance in a battle with the Philistines (1 Sam. vii. 10-12). Two earlier battles were fought at this place between the Israelites and the Philistines, in both of which the Israelites were beaten, and in the second of

which the Ark of the Covenant was captured (1 Sam. iv. 1-2, 3-11). The location of the place cannot be satisfactorily determined.

EBENSBURG, ɛ'benz-bürg. A borough and the county seat of Cambria Co., Pa., 16 miles (direct) west of Altoona, on the Pennsylvania Railroad (Map: Pennsylvania, D 6). It is situated in the Alleghenies, about 2025 feet above sea level and is a resort. Ebensburg is in a rich bituminous coal region and has saw mills, tanneries, woolen mills, a foundry, etc. Pop., 1900, 1574; 1910, 1978.

EBER. See HEBREWS.

EBERHARD, ɛ'bër-härt, surnamed IM BART (1445-96). The fifth Count and first Duke of Württemberg. He was the son of Count Louis the Elder and succeeded his brother at the age of 12; at 14 he wrested the government from his uncle Ulrich, who had been appointed his guardian. He paid no attention to government affairs, but indulged his passions and led a dissipated life. In 1468 he made a pilgrimage to Jerusalem, after which he abandoned his reckless mode of living and ruled well. He married Barbara of Mantua, whose influence over him contributed largely to the elevation of his character. He began to study, gathering around him men of learning, and founded, in 1477, the University of Tübingen. In 1482 Eberhard, by the Treaty of Mühlhausen, put an end to the division of his principality, made in 1437 between his father and his uncle Ulrich as representatives of the two lines of Urach and Stuttgart. By this treaty he secured the future integrity of Württemberg and established the right of primogeniture in his own family; he became at the same time the founder of the representative constitution of Württemberg. He made Stuttgart his place of residence and improved the government of the convents in his territories. Although he preferred peace, he was an able warrior. His courage and his fidelity to his engagements secured the esteem and friendship of the emperors Frederick III and Maximilian I. In recognition of his services the latter, in 1495, raised Eberhard to the dignity of Duke, confirming at the same time all the possessions and prerogatives of his house. He died Feb. 24, 1496. Consult Bossert, *Eberhard im Bart* (Stuttgart, 1884).

EBERHARD, CHRISTIAN AUGUST GOTTLÖB (1769-1845). A facile German poet and romancer, with a leaning to the older poets of the eighteenth century, born at Belzig. The more noteworthy of his many works are the often reprinted idyl, *Hannchen und die Küchlein* (1822), still popular with the young, and *Der erste Mensch und die Erde* (1828).

EBERHARD, JOHANN AUGUST (1739-1809). A German philosophical writer. He was born at Halberstadt, studied theology at Halle from 1756 to 1759, and after spending several years as a preacher in Berlin and Charlottenburg became professor of philosophy at Halle in 1778. Among his writings were treatises on ethics, æsthetics, the history of philosophy, and synonymy; especially notable were the *Neue Apologie des Sokrates* (1772-73) and *Allgemeine Theorie des Denkens und Empfindens* (1776). He was a Leibnitzian and toward the close of his life struggled, but without success, against the speculative views of the new schools of philosophy headed by Kant and Fichte.

EBERLE, ɛ'bër-le, ROBERT (1815-60). A German animal and landscape painter, born at Meersburg on Lake Constance. At first a pupil

of Jakob Biedermann at Constance, he went to Munich in 1830, where he was much influenced by the works of Ruysdael and Dujardin in the Pinakothek. In 1848 he spent three months in America, but he returned to Munich, where he died from the effects of an accidental pistol shot. He is particularly noted as a painter of sheep. His pictures are distinguished for good drawing and striking light effects. Among the most noteworthy are: "Shepherd Killed by Lightning beside his Flock" (1842), National Gallery; "Sheep and Cattle in Stable," Leipzig Museum; "Suabian Shepherd with Flock" (1853), Pinakothek, Munich; "Sheep Driven over Precipice by an Eagle" (1858), Karlsruhe Gallery.—His son ADOLF (1843-), born in Munich, is equally successful as a genre and animal painter. He studied at the Munich Academy, especially under Piloty. One of his best rural genre scenes, the "Seizure of the Last Cow" (1861), is in the Hamburg Gallery. Others are: "After the Baptism" (1868), for which he was awarded a medal in Vienna; "The First Deer" (1879); "Forester's Belated Dinner" (1888); "A Lucky Catch" (1891).

EBERLEIN, ɛ'bër-lin, GUSTAV (1847-). A German sculptor, born at Spiekershausen (Hanover). He studied at the Art Academy of Nuremberg and at Berlin under Blaaser, a pupil of Rauch. After a short sojourn in Rome he returned to Berlin and allied himself with the so-called realistic group of sculptors, of which Reinhold Begas (q.v.) is the chief representative. In his work temperament and ability are united with a strong feeling for decorative effects; his ideal statues seek to combine the forms of ancient art with modern sentiment. Good examples of the latter are "Boy Extracting a Thorn" (National Gallery, Berlin), with which he first made a name; "Greek Flute Player," and "The Secret." He also carved a number of religious pieces, prominent among which are groups depicting the life of Adam and Eve; while among his decorative works the frieze of the Berlin Ministry of Public Instruction, containing 50 life-size figures, deserves mention. But Eberlein's reputation rests chiefly upon his public monuments, such as those of William I at Elberfeld, Mannheim, and Ruhrort; Bismarck at Krefeld, Richard Wagner in Berlin, and Goethe in Rome; and the heroic statues of Queen Louise at Tilsit, and King Frederick I and Frederick William III in the Siegesallee, Berlin. He published in 1892 *Aus eines Bildners Seelenleben, Plastik, Malerei und Poesie*. Consult Rosenberg, *Eberlein* (Bielefeld, 1903).

EBERNBURG, ɛ'bër-n-bōrk. A village in the Bavarian Palatinate, situated at the junction of the Alsenz with the Nahe, 20 miles southwest of Mainz (Map: Germany, C 4). It is notable on account of its castle, built on the site of an ancient one, which once belonged to the famous knight Franz von Sickingen, friend of the early Reformers. His stronghold sheltered Melanchthon, Schwebel, Bucer, Ecolampadius, and also Ulrich von Hutten, the most distinguished bard of the Reformation and apostle of German unity. Hutten composed several of his works here. The castle was destroyed by the French in 1794 and rebuilt in 1841. The Hutten-Sickingen Monument, halfway up the hill, was unveiled in 1889. Pop., about 800. Consult Schneegans, *Die Ebernburg* (Kreuznach, 1888).

EBERS, ɛ'bërs, EMIL (1807-84). A German

genre painter, born in Breslau. He was a pupil of the Dusseldorf Academy, where he was much influenced by Lessing, Jordan, and Ritter. In company with the latter two he visited the coasts of Holland and Normandy and became much interested in the life of smugglers, fishermen, and sailors, from which the subjects of his best pictures are chosen. He also painted humorous military scenes. His works show good composition, careful study of detail, and harmonious coloring. The most noteworthy are: "Smugglers about to Land" (1830), National Gallery, Berlin; "Rescued Women" (1841); "Pilot Boat" (1841); "On a Brig" (1848), Breslau Museum.

EBERS, GEORG MORITZ (1837-98). A German Egyptologist and novelist, born in Berlin. In 1856 he entered the University of Göttingen as a student of law, but soon became interested in Egyptology and devoted himself to that study in Berlin under Lepsius, Brugsch, and Boeckh. In 1862, he spent the next year at work in the principal Egyptological museums of Europe. In 1865 he became lecturer and in 1869 associate professor of Egyptology at Jena. In 1869 and 1870 he traveled extensively in Egypt and Nubia and in the latter year accepted a call to Leipzig as associate professor. Two years later he again visited Egypt, where he discovered the celebrated hieratic medical papyrus, since known as the *Papyrus Ebers*. Dating from about 1550 B.C., it is one of the best-preserved Egyptian papyri in existence, and forms the chief source of information in regard to the medical knowledge of the ancient Egyptians. A facsimile (110 plates) was published in 1875 by the discoverer, with an introduction written by himself and a hieroglyphic-Latin glossary by L. Stern. The papyrus is now in the library of the University of Leipzig. Among Ebers's scientific works may be mentioned his *Disquisitiones de Dynastia XXVI Regum Egyptorum* (1865) and *Aegypten und die Bücher Moses* (1868). His *Durch Gosen zum Sinai* (1872; 2d ed., 1881) is partly of a popular character. He also wrote *Aegypten in Wort und Bild* (2 vols., illustrated, 2d ed., 1880), and *Richard Lepsius, ein Lebensbild* (1885). Ebers's reputation as a novelist was established by his *Eine ägyptische Königstochter* (1864), a charming picture of Egyptian life at the time of the Persian conquest. Of his later novels, *Uarda* (1877), *Homo Sum* (1878), *Die Schwwestern* (1879), *Der Kaiser* (1881), and *Serapis* (1885) deal with periods of Egyptian history. Others of his novels, among them *Die Frau Bürgermeisterin* (1881), *Ein Wort* (1882), and *Die Gred* (1887), are located either in Holland or South Germany in the sixteenth century, while his *Eine Frage* (1881) is an idyl of ancient Greek life. In 1887 he brought out his novel *Die Nilbraut* and in 1894 *Kleopatra*. In 1876 Ebers became partially paralyzed and for the rest of his life suffered from continued ill health. He usually spent the summer at his country place at Tutzing, near Munich, and there he died. An excellent sketch of Ebers by the historian Eduard Meyer is to be found in *Biographisches Jahrbuch und deutscher Nekrolog*, vol. iii (Berlin, 1898). His own *Die Geschichte meines Lebens* (Stuttgart, 1893) should also be consulted.

EBERSWALDE, ä'bërs-väl'de. A town and health resort of the Prussian Province of Brandenburg, situated on the Finow Canal, at its

junction with the Schwärze, about 27 miles north-northeast of Berlin (Map: Prussia, E 2). It has a forestry school, a gymnasium, and schools of domestic economy, and is a favorite summer resort on account of its delightful situation in the midst of fine groves and pine forests. It has mineral springs. It is an industrial centre, having extensive manufactures of railway cars and locomotives, horseshoe nails, roofing, felt, and cement. There is considerable trade in coal, wood, and grain. Near by are large brass foundries and a government mill at which paper is made for bank notes. Pop. 1900, 21,619; 1905, 23,846; 1910, 26,064.

EBERT, a'bërt, ADOLF (1820-90). A German philologist, born at Cassel. He studied at Marburg, Leipzig, Göttingen, and Berlin, became professor at Marburg, and in 1862 professor of Romance philology at Leipzig. From 1862 to 1873 he also held the chair of English philology. His most important work is his *Allgemeine Geschichte der Litteratur des Mittelalters im Abendlande* (3 vols., 1874-87; Fr. trans. by Aymeric and Condamin, Paris, 1883-89). In 1859 he established with Ferdinand Wolf the *Jahrbuch für romanische und englische Litteratur*, to the first five volumes of which he contributed. His study was directed chiefly towards an examination of the connection between the Romance literature of the Middle Ages and the Latin and German literature of the same period. Among his publications may be mentioned: *Quellenforschungen aus Geschichte Spaniens* (Kassel, 1849); *Handbuch der italienischen National-Litteratur* (Marburg, 1854); *Geschichte der christlich-lateinischen Litteratur von ihren Anfängen bis zum Zeitalter Karls des Grossen* (Leipzig, 1874).

EBERT, KARL EGON (1801-82). An Austrian poet, of the school of A. Grün and Lenau. He was born at Prague and was educated there and at Vienna, and after filling several positions settled in Prague. His chief works are his *Dichtungen* (1824; 3d ed., 1845); *Wlasta, ein böhmisch-nationales Heldengedicht in drei Büchern*, a true epic, but perhaps too rhetorical; *Das Kloster, idyllische Erzählung in fünf Gesängen* (1833), one of his best works, plainly under the influence of Goethe's *Hermann und Dorothea*; the dramatic poem, *Bretislav und Jutta* (1835); a collection of sonnets entitled *Ein Denkmal für Karl Egon, Fürsten von Fürstenberg* (the poet's godfather) (1855); and the didactic poem *Fromme Gedanken eines weltlichen Mannes* (1859). He likewise wrote a large number of dramas, of which *Das Gelübde* was the best. His best work was in the field of the lyric and the ballad. His poetical works were published in 7 vols. (1877).

EBERTH, a'bërt, KARL JOSEF (1835-). A German bacteriologist and anatomist. He was born at Würzburg, studied at the University there, became professor of pathological anatomy at Zurich in 1865, and in 1881 was called to a similar chair at Halle. The results of his anatomical researches, including "Ueber den Peitschenwurm" (1859) and "Ueber Nematoden" (1863), appeared chiefly in Rudolph Virchow's *Archiv für pathologische Anatomie*. His investigations as a bacteriologist have to do principally with the bacillus of typhoid fever. His writings include: *Die Untersuchung des Auswurfs auf Tuberkulizität* (1891); *Die Thrombose*, with Schimmelbusch (1888); *Mikroskopischer Technik* (1900).

EBING, RICHARD, BARON VON KRAFFT. See **KRAFFT-EBING.**

EBINGEN, ˈɛbɪŋən. A town in the Black Forest district of Württemberg, Germany, 37 miles south of Tübingen by rail, situated amid beautiful hill scenery (Map: Germany, C 4). It has manufactures of woollens, clothing, velvet, stockings, hats, and leather. Pop., 1900, 9001; 1910, 11,423.

EBIONITES, ˈɛbɪ-ō-nīts (Lat. *Ebionitæ*, from Heb. ʿebyonim, poor). A name employed, because of its Hebrew origin, to designate Christians of Jewish blood. Still later, when Jewish Christians had separated from the great body of the Church and displayed heretical tendencies, the name was applied to them. Isolated as they now were, they fell into a number of sectarian divisions, to one of which in particular the term was sometimes confined (in distinction from a more moderate sect called the Nazarenes). Irenæus describes the Ebionites as Jewish Christians who hold to the Mosaic law, reject Paul as an apostate, deny the miraculous birth, and regard Christ as a mere man. Origen styled all Jewish Christians Ebionites and distinguished two classes, one of which accepted and the other denied the virgin birth. The most detailed accounts are found in Epiphanius, *Against Heretics*. They lingered in Palestine and Syria till the fifth century, but were few and unimportant after the second. Consult Harnack, *History of Dogma* (Boston, 1894-1900), and Rainy, *The Ancient Catholic Church* (New York, 1902). See **CLEMENT OF ALEXANDRIA**; **ESSEXES**; **OLD CATHOLICS**.

EB/LIS. See **IBLIS.**

EBNER-ESCHENBACH, ˈɛb-nər ɛʃ-ən-bäç, MARIE, BARONESS VON (1830-1916). A distinguished Austrian novelist. Born at Castle Zdislawitz, Moravia, her maiden title being Countess Dubsky, she married, in 1848, an Austrian officer, who died in 1898. She lived alternately at her birthplace and in Vienna. Her first publications are dramas now unimportant. Her fiction, which attracted immediate attention, begins with *Erzählungen* (1875). This was followed by: *Božena* (1876); *Neue Erzählungen* (1878); *Dorf- und Schlossgeschichten* (1884); *Zwei Comtessen* (1885; Eng. trans.); *Neue Dorf- und Schlossgeschichten* (1886); *Das Gemeindekind* (1887); *Lotti die Uhrmacherin* (1889); *Ein kleiner Roman* (1889); *Miterlebtes* (1890); *Unsühnbar* (1890; Eng. trans.); *Margarete* (1891); *Drei Novellen* (1892); *Glaubenslos* (1893); *Das Schädliche* and *Die Totenwacht* (1894); *Rittmeister Brand* and *Bertram Vogelweid* (1896); *Alte Schule* (1897); *Aus Frühherbsttagen* (1901); *Agave* (1903); *Die unsiegbare Macht* (1904); *Die unsiegbare Macht* (1905); *Meine Kinderjahre* (1906); *Ein Buch für die Jugend* (1907); *Volksbuch* (1909); *Altweibersommer* (1909); *Genrebilder* (1910). Among her dramatic works are: *Dr. Ritter* (1872); *Ohne Liebe* (1891); *Am Ende* (1897). She wrote also a popular collection of *Aphorismen* (1880) and verses collected as *Parabeln, Märchen und Gedichte* (1892). Her collected works were published in 1893-1911. Her work is distinguished for its power of description, its psychological insight, its humor, wit, and polished precision of style. Her sense of proportion in novelistic construction has also been highly praised. For her biography, consult Necker (Berlin, 1900) and Bettelheim (ib., 1900).

EBOLI, ˈɛb-ō-lé (Lat. *Ebura* or *Eburum*). A

city of Campania, in South Italy, 50 miles south-east of Naples (Map: Italy, K 7). It is picturesquely situated on a hill above the river Sele, a few miles from the Gulf of Salerno. Pop., 1901, 12,407; 1911, 12,741.

EBOLI, ANNA DE MENDOZA DE LA CERDA, PRINCESS OF (1540-92). A Spanish courtier, with the further titles of Duchess of Francavilla and Princess of Melito. She was a prominent and influential figure at the court of Philip II of Spain and played a conspicuous rôle in many of the intrigues of the time. She was the wife of that proud old nobleman Ruy Gómez de Silva, Prince of Eboli and one of the most trusted advisers of Philip II, and she became the mistress of Philip II and of his favorite the traitor Antonio Pérez, carrying on the intrigue with sovereign and favorite at the same time. She is best known as a character in Schiller's drama *Don Carlos*, and more recently she appeared in Marion Crawford's novel *In the Palace of the King*, where her rôle accords better with the known facts of history.

EB'ONY (older form *ebon*, OF. *ebene*, Lat. *ebenus*, Gk. ἔβερος, *ebenos*, ebony; probably of Sem. origin; cf. Heb. pl. *hābñim*, ebony, lit. dark, ultimately probably of Egyptian origin). The hard, heavy, and dark-colored heartwood of a number of species of trees. The genus *Diospyros*, of the family Ebenaceæ, is the source of most of the ebony of commerce. The best quality is obtained from *Diospyros ebenum*, a large tree of India, Ceylon, and other tropical countries. Logs of ebony of this species, 10 to 15 feet in length, with the heartwood 2 feet in diameter, are common. Ebony of good quality is obtained in Coromandel from *Diospyros melanoxylon* and also from *Diospyros tomentosa* and other species of India, Madagascar, and Mauritius. The Calamander wood is from *Diospyros hirsuta*; the Calabar wood is a peculiar kind of wood of the same effect obtained from *Diospyros ebenum*. Ebony is furnished by *Maba ebenus* of Mouloua and by a number of trees of the family Leguminosæ. Among these latter may be mentioned a variety obtained in Abyssinia from *Milletia* and the West Indian ebony (*Brya ebenus*). The American species of *Diospyros* (*Diospyros virginiana* and *Diospyros tawana*) often supply a fairly good quality of ebony. The wood is chiefly used as a veneer by cabinetmakers. It is very heavy and takes a high polish. The beauties of this wood were well known to the Greeks and Romans, who inlaid it with ivory for contrast. It is mentioned in the Scriptures as an article of Tyrian importation. The wood is somewhat pungent and was once thought to have medicinal value. Ebony is exported in considerable quantity from Egypt, Zanzibar, Madagascar, Ceylon, India, and Jamaica. A variety of bastard ebony is exported in considerable quantities from Brazil. It is produced by the tree *Jacaranda ovalifolia*. True ebony wood is so intensely dark in color that the term "black as ebony" is a well-known colloquialism. Imports into the United States in 1913, \$90,133. See **JACARANDA WOOD**.

EBONY, MOUNTAIN. See **BAUHNIA**.

EBORA. See **EBURA**.

EBOR'ACUM. See **YORK**.

EBRARD, ˈɛbr-ärt, JOHANNES HEINRICH AUGUST (1818-88). A German Reformed theologian and miscellaneous writer. He was born at Erlangen, Jan. 18, 1818. He studied there and at Berlin, became professor at Zurich in

1844, at Erlangen in 1847, removed to Speyer in 1853, but in 1861 returned to Erlangen and resumed his lectures. From 1875 he was pastor of the French Reformed church at Erlangen. He was a voluminous writer both in theology and lighter literature. Those of his theological works translated into English include *The Gospel History* (1863) and *Apologetics* (1886-87). He also published: *Die irisch-schottische Missionskirche des sechsten bis achten Jahrhunderts* (1873); *Bonifatius, der Zerstörer des columbanischen Kirchentums auf dem Festlande* (1882); *Lebensführungen* (1888); *Christliche Dogmatik* (1851); commentaries on Hebrews and Revelation; and many dramas, poems, etc. When writing upon nontheological subjects he generally used a pseudonym—Gottfried Flammberg, or Sigmund Sturm. He died at Erlangen, July 23, 1888.

EBRO (Lat. *Iberus*). One of the largest rivers of Spain, rising in the Province of Santander, in the north-central part of the country, on the south slope of the Cantabrian Mountains (Map: Spain, E 2). After a tortuous course in a southeasterly direction of about 450 miles, it empties into the Mediterranean at Cabo de Tortosa. It drains an area of about 30,000 square miles and has a delta which extends far into the sea. Its mouth is choked up with sand, and, to render it navigable, a canal called the San Carlos has been carried through the south side of the delta. Its principal affluents are the Najerilla, Jalon, Huerva, and Guadalepe from the right, and the Aragon, Gallejo, and Segre from the left, which drain the south slopes of the Pyrenees. The large supply of water brought to it by the Aragon and Segre renders the Ebro particularly advantageous for irrigating the lowlands of Aragon. The course of the Ebro is chiefly through narrow and sometimes rocky valleys; its bed is characterized by many shoals and rapids which interrupt the navigation. This is partly remedied, however, by means of the Imperial Canal, which extends from the vicinity of Tudela to a point 40 miles below Saragossa, the principal city on the river.

EBERTH, ERSTIN, WILHELM (1836-1912). A German physician, born at Jauer, Silesia. He was educated at Breslau and Berlin and in 1874 became professor of medicine at the University of Göttingen and director of the Medical Polyclinical Institute at that institution, and from 1877 to 1906 he was at the head of the medical clinic. His writings, several of which contain valuable suggestions as to dietetic cures, include: "Nierenkrankheiten," vol. ix of Ziemssen's *Handbuch* (2d ed., 1878); *Die Fettleibigkeit (Korpulenz) und ihre Behandlung nach physiologischen Grundsätzen* (7th ed., 1887); *Die Kunst das menschliche Leben zu verlängern* (1891); *Lebensweise der Zuckerkranken* (2d ed., 1898); *Handbuch der praktischen Medizin*, with Dr. Julius Schwalbe (1898); *Die Medizin im neunzehnten Jahrhundert* (1901); *Die Medizin im Neuen Testament* (1903); *Die Pathologie und Therapie der Lepra* (1909).

EBULLIOSCOPE (Lat. *ebullire*, to boil, from *e-*, out + *bullire*, to bubble, from *bullo*, bubble + Gk. *σκοπεῖν, skopein*, to look). An apparatus for ascertaining the boiling temperature of liquids, such as distilled liquors, and more especially for observing the changes of boiling temperature caused by dissolving comparatively nonvolatile substances in a given liquid. The best-known ebullioscope is that devised by

Beckmann. It is used mainly for determining the molecular weights of soluble substances, the principle involved being that the elevation of the boiling point of a liquid caused by dissolving in it, say, 1 gram of a given substance, is inversely proportional to the molecular weight of the substance. Concerning the theory and practice of ebullioscopic determination of molecular weights, consult Rosanoff and Dunphy, in the *Journal of the American Chemical Society* for 1914. See MOLECULES—MOLECULAR WEIGHTS.

EBULLITION, or **BOILING**. See **HEAT**.

EBURA, or **EBURUM**. See **EBOLI**.

ÊÇA DE QUEIROZ, a'sä da ka'e-rôsh, José MARIA (1845-1900). A Portuguese author, born at Povoá do Varzim. He was educated at the University of Coimbra, was a collaborator on the staff of *As Farpas*, a critical journal, in 1871, and was appointed Consul successively at Havana, Mexico, and Paris. His best-known publications are his works of prose fiction, *O crime do Padre Amaro* (1874; thoroughly rewritten and revised edition, 1880), *O primo Basílio* (1877; in French translation by Rattazzi-Ruth, German by C. and H. Michaelis), and *A Reliquia* (1886; 2d ed., 1891), together with his short stories. The best of the latter, *O Defunto*, was done into excellent English, under the title of *Our Lady of the Pillar*, by Edgar Prestage (London, 1906), with a brief introduction, and a frontispiece showing the beautiful monument erected to Queiroz in Lisbon by the devotion and friendship of the Conde de Arnoso and other admirers. Prestage had previously translated and published, with a critical preface, *A Suave Milagre*, which has already gone through three editions in England and one in America, as *The Sweet Miracle*. An unsatisfactory English rendering of *O primo Basílio* appeared in Boston (1889) under the title *Dragon's Teeth*. Consult the series of essays by J. Pereira de Sampaio (Bruno) entitled *A Geração Nova* (Porto, 1886), and the number for Nov. 20, 1897, of the *Revista Moderna*, which was entirely devoted to Queiroz. Batalha Reis gives reminiscences of Êça's early days, in his preface to some prose fragments that he edited under the title of *Prosas Barbaras* (Porto, 1903).

ECARDINES. See **BRACHIOPODA**.

ÉCARTÉ, a'kär'tä' (Fr., discarded, p.p. of *écarter*, to discard, from Lat. *ex*, out + *charta*, Gk. *χάρτης, chartēs*, paper). A game of cards usually played by two persons, though, in the form called pool écarté, three or even more may take part in it. In this case the third player takes the place of the loser in the first game, and the fourth player takes the place of the loser in the second game. In French écarté bystanders are permitted to advise, and the player losing leaves the table, his adviser taking his place. If, however, the loser is playing *la chouette* (i.e., taking all bets offered), he need not retire on losing. The sixes, fives, fours, threes, and twos are removed from a pack, and the player cutting highest deals. He gives five cards, by two and three at a time, to his opponent and himself and turns up the eleventh card for trumps. The trump card, if a king, counts one for the dealer. His adversary, if satisfied with his hand, plays; if not satisfied, proposes, which means, briefly, that he wishes to get rid of poor cards and take up others from the stock, and the dealer can accept or refuse.

Should he accept, each may discard, face downward, as many cards as he may choose, receiving fresh ones from the cards yet undealt, these being given first to the nondealer till his hand is complete. A second proposal and a third may be made, and so on till the player is satisfied; but if the dealer refuse, the hand must be played without discarding. The king of trumps scores one if in either hand. The nondealer, being satisfied with his hand, leads; the dealer follows, and the trick is taken by the highest card or the trump. The king is the highest. The winner of a trick leads to the next. The second player must follow suit and must win the trick if he can. The game is scored by the king, as explained, and the majority of tricks. Three tricks score one for the point; all five tricks won by one player score two for the *vole*. When the nondealer does not propose, or his proposal is refused, and he fails to gain three tricks, the dealer scores two, but no more, even though he win the *vole*. The game is five up. The rules are very complicated and vary in different countries. The game is described at length in *Foster's Complete Hoyle* (New York, 1909), whose compiler says he presents "what appears to be the best French usage." Consult also Cavendish, *Pocket Guide to Ecarté* (London, 1897); *The Laws of Ecarté Adopted by the Turf Club* (ib., 1897).

ECBATANA (OPers. *Hangmatāna*, written *Ḥangmatāna*; place of assembly, from *ham*, Skt. *gam*, to come; Babyl. *Agamatanu*, *Agamtanu*, Heb. *Achmētha*, Lat. *Ecbatana*, Gk. *Ἐκβάτανα*, *Ekbatana*, *Ἀγβάτανα*, *Agbatana*). The ancient capital of Media. It was situated at a distance of 12 stadia (about 1½ miles) from Mount Orontes, the modern Elvend. It lay upon a conical hill, crowned by a temple of the sun, and was inclosed by seven concentric walls, the innermost of which was gilded and the next plated with silver; while the rest, in their order outward, were painted orange, blue, scarlet, black, and white. The city is said to have been nearly 30 miles in circumference. Its principal buildings were the citadel—a stronghold of enormous dimensions, where also the archives were kept in which Darius found the edict of Cyrus the Great concerning the rebuilding of the temple at Jerusalem—and the royal palace. The mild climate and the beauty of its structure singled out it as the favorite summer residence, first, of the Median, then of the Persian, and lastly of the Parthian monarchs. After the battle of Arbela (331 B.C.) Alexander followed Darius thither and secured immense booty. It was again pillaged by the Seleucidæ; but such were the riches of this place that Antiochus the Great still found 4000 talents' worth of silver, equivalent to more than \$4,000,000, to carry away. Ecbatana subsequently fell into the hands of the Parthians, and it has since so utterly sunk into decay that its site can no longer be fixed upon with certainty. But nowadays scholars generally agree that the present Hamadan, with the reputed tombs of Mordecai and Esther (see *HAMADAN*), occupies the site of ancient Ecbatana. Excavations on the site would no doubt yield valuable finds in the way of antiquities. There was another Ecbatana in Persia, which was given to the Magi, and a third in Syria, at the foot of Carmel, the present Haifa, where Cambyases, the son

of Cyrus, died. Consult: Barbier de Meynard, *Dictionnaire géographique de la Perse* (Paris, 1861); De Morgan, *Expédition scientifique en Perse*, vol. iv (1896); Pauly-Wissowa, "Ekbatana," in *Real-Encyclopædie*, vol. v (1905); A. ECCARD, *ék'kärt*, JOHANNES (1553-1611). A German composer of church music. He was born at Mühlhausen (Thuringia), was a pupil of Orlando Lasso at Munich, and became assistant conductor in 1583 and chapelmaster in 1599 at Kassel. In 1608 he was chief conductor of the Elector's chapel in Berlin. His songs, cantatas, and chorales live by reason of their harmony and religious feeling. Among the collection of his songs are *Geistliche Lieder* (1579) and *Preussische Festlieder* (1642, posthumous).

ECCE HOMO, *ék'sé hō'mō* (Lat., Behold the Man). This expression is derived from the words spoken by Pilate on showing Christ to the multitude (John xix. 5) previous to His being led forth to crucifixion, and is applied to paintings . . . of Christ bound and crowned with . . . the most celebrated representations of the subject are those by Sodoma in the Pitti Palace (Florence) and the Siena Academy; by Correggio in the National Gallery (London); by Titian in the Scuola di San Rocco (Venice) and the museums of Madrid and Vienna—the latter a very large canvas of almost repellent realism; by Tintoretto in the Munich Gallery and the Scuola di San Rocco; by Guido Reni, whose well-known heads of "Christ Crowned with Thorns" are in the Dresden Gallery, the Louvre, and the National Gallery (London); and by Murillo in the Cadiz Museum, the Prado (Madrid), and the collection of Lord Ashburton (London).

ECCE HOMO: A STUDY OF THE LIFE AND WORK OF JESUS CHRIST. A religious work by John Robert Seeley, professor at Cambridge University, England, which appeared anonymously in 1865.

ECCEN'TRIC (from Lat. *eccentros*, Gk. *ἐκκεντρος*, *ekkēntros*, eccentric, from *ék*, *ek*, out of + *κέντρον*, *kētron*, centre). A mechanical contrivance for obtaining an . . . rectilinear motion from a revolving . . . consists of a cylindrical disk, mounted on a revolving shaft with its axis parallel to that of the shaft, but having its centre of figure not in the axis of revolution. It is in effect a crank, whose crank pin is of a diameter greater than that of the shaft which actuates it. The disk has usually a groove on its cylindrical surface, into which fits a metallic hoop or band or strap, to which is attached the eccentric rod which has the alternating linear motion. As the eccentric revolves with the shaft, the strap is alternately forced out and in, thus imparting a to-and-fro motion to the rod. The extent of the rise and fall of the rod is equal to twice the distance between the centres. The eccentric is used where the harmonic motion of the crank and connecting rod is desired, but where the stroke or traverse of the rod must be less than the diameter of the shaft which revolves, or is to take place where crank construction would not be feasible, as in the middle of a long or massive shaft. This adapts it for use in operating valves of steam engines, or for working pumps for feed water or compressing air. See **CRANK**; **STEAM ENGINE**.

All full citizens over 30 years of age were at liberty to attend. There was no free debate, and as a rule only the officials seem to have spoken: there was no right to alter the proposals laid before the assembly. It is not known what was the nature of the little ecclesia at Sparta mentioned once by Xenophon. The voting at Sparta was by acclamation and not by ballot. The majority was determined by the comparative volume of sound, or, if that was doubted, by a division and conflict of the two parties.

2. In the Greek of the New Testament, *ecclesia* is the name for the company of Christ's disciples professing to trust Him as their Saviour and to obey Him as their Lord. It is applied to a small assembly of them, such as were members of one family or could meet in a dwelling house of ordinary size; to the whole number in one city or town; to the whole number on earth; to the whole number in heaven; and to the innumerable company on earth and in heaven. It has other meanings, but is usually rendered *Church*.

ECCLESIASTES, *ek-kle'zi-ās'tēz* (Lat., from Gk. *ἐκκλησιαστής*, *ekklēsiastēs*, one concerned with an assembly, from *ἐκκλησία*, *ekklēsia*, assembly). A philosophical book belonging to the third division of the Old Testament collection known as Hagiographa. The Hebrew name is *Koheleth*, which is translated into Greek as *Ecclesiastes*, on the supposition that the Hebrew stem underlying *Koheleth* is to be taken in the sense of assembly, so that *Koheleth* is one who addresses or convenes an assembly, i.e., a preacher. This explanation of the name, however, is doubtful, a strong objection to it being that it does not account for the feminine ending which the Hebrew word exhibits. To assume, as some scholars are inclined to do, that the speaker is "personified wisdom" (and hence the feminine) is not satisfactory, since nowhere is wisdom mentioned as the speaker. Various other explanations have been brought forward, none of which, however, has met with general acceptance. *Koheleth* impresses one as an intentional disguise and therefore a more or less artificial formation, and since *kahal* is a characteristic Hebrew word for "congregation," it is not impossible that by inventing the form *Koheleth* the author intends to carry the idea of anonymity. *Koheleth* would thus be about the equivalent of our "anonymous."

The book itself consists of 12 chapters, forming a series of discourses on the vanity of earthly things, and is put into the mouth of *Koheleth*, who describes himself as "a son of David, king in Jerusalem" (i. 1). Whether Solomon was originally in the mind of the author is not certain, for "son of David" may be an interpolation: but it is probable, for, to the Jews of the postexilic period, to which *Ecclesiastes* belongs, Solomon had become the ideal of a king endowed with wisdom, riches, and power, and who therefore could properly be chosen as an illustration for the central doctrine of the author's philosophy. To prove the theory of the vanity of life it was necessary to choose some one who could represent life in all its manifestations. Solomon was such a man, and the author's argument is that if Solomon came to the conclusion that wisdom, pleasures, riches, power, were all vain, there could be no doubt about it. The introduction of Solomon by implication gave rise to the tradition which ascribed the authorship to Solomon.

This tradition prevented a proper understanding and gave rise to methods of interpretation that disguised the real character of the book, which is undoubtedly skeptical. Everything is questioned—the value of virtue, immortality, divine justice, the providence of God, the advantage of wisdom. The character of the skepticism is peculiarly Oriental. The tone is the same that we find in Omar Khayyam. Yet the influence of Greek thought is unmistakable. It is not only Stoic, but also Epicurean and Heraclitian, speculation with which, though not necessarily through written documents, the author shows acquaintance. The book must belong to a period of depression in the history of the Jews when internal conditions suggested a doubt as to the validity of the prophetic teachings which had emphasized God's providence for Israel, His justice and goodness, and the necessity of virtue and morality as a condition to securing divine favor and with it happiness. Such a period sets in towards the close of the Persian dominion, and the depression became accentuated from age to age. Hence scholars vary considerably in assigning a date to *Ecclesiastes*; several are inclined to bring the date of the composition down to the days of Herod, while others are inclined to see an allusion to the siege of Syracuse by the Romans in 212 B.C. in iii. 13-18 and consequently place the book about 200 B.C. The language points to a late date. The discovery of the Hebrew text of *Ecclesiasticus* has naturally led to comparisons, and Nöldeke, *Zeitschrift für alttestamentliche Wissenschaft*, pp. 90 ff. (1900), expressed the view that *Ecclesiasticus* is somewhat older. The song of *Youth and Age*, a poem in form as well as in spirit, as Schmidt has shown, is manifestly the work of another man than the original author.

Ecclesiastes became a popular book, much to the alarm of pious Jews, who shrank from its skeptical tone and conclusions. Hence the attempt was made to modify its most audacious utterances, to intersperse throughout the book phrases indicative of the author's piety, and above all, by adding a pious conclusion, to give to the book a religious touch. This was done with such success that the skeptical tone was disguised and the book, though not without discussion by the Jewish rabbis, was allowed to remain among the books used in the synagogue and considered as sacred.

ECCLESIASTICAL COMMISSIONERS FOR ENGLAND. A corporate body established by act of Parliament, charged with the oversight of the estates belonging to the church.

The commissioners are about 50 in number and include all the bishops of the Established church in England, Wales, the deans of Canterbury, Exeter, and Westminster, and five cabinet ministers, in addition to 12 lay members, appointed partly by the crown and partly by the Archbishop of Canterbury. They are required to lay before the crown in council such plans as appear to them best adapted for carrying out the objects of their appointment. By acts subsequent to their organization they now have authority to divide or unite existing parishes and to create additional jurisdictions, known as districts. At the time of their appointment, in order that they might be provided with funds to carry out their plans, the seven best-endowed sees of the Established church were laid under a contribution which amounted to an annual sum of £22,800. In addition to the income thus provided, several canonries in various cathedrals and other ecclesiastical preferments were suppressed, and the entire emoluments were vested in the commissioners.

The commissioners expend their funds on church buildings, on the augmentation of poor livings, and on the endowment of new churches in new cures, called districts; and in so doing, though the fund they handle is a common one, they are bound to consider the needs of the places whence the income is derived. In the augmentation of poor livings the commissioners often contribute a certain sum on condition that the persons interested raise an equal sum. Consult Whitehead, *Church Law* (London, 1892), and Cripps, *Law Relating to the Church and Clergy* (ib., 1886).

ECCLESIASTICAL CORPORATION. A body corporate constituted of an ecclesiastical person or persons and subject to ecclesiastical judicatories. Ecclesiastical corporations are divided into corporations aggregate and corporations sole. The former consist of several persons—as, e.g., the head and fellows of a college or the dean and chapter of a cathedral—and are perpetuated by a continuous succession of members. The latter consist of a single person and his successors in a certain office—as, e.g., a bishop or rector. By the law of England the holder of an ecclesiastical benefice is regarded as a corporation. The object of the law in regarding the incumbent of a benefice as a corporation sole is to preserve the temporalities vested in him, which would otherwise descend to his natural heirs. The right of a rector or other corporation sole to church temporalities, although generally spoken of as a freehold in law, is in fact practically nothing more than a tenancy for life. Such a corporation sole is entitled to the full enjoyment of the benefice during his life, but he cannot sell it, and he is even punishable for waste.

The corporation for religious purposes, as it has developed in American law, bears little resemblance to the ecclesiastical corporation of the English law; for while the objects for which they exist are much the same, the American body is purely a civil corporation and subject to the civil tribunals. Of recent years provisions for the creation of ecclesiastical corporations sole have been introduced into the statutes of several States. See CORPORATION; CIVIL CHURCH LAW, AMERICAN.

ECCLESIASTICAL COSTUME. See COSTUME, ECCLESIASTICAL.

ECCLESIASTICAL COURTS. Tribunals having jurisdiction more especially in causes relating to the discipline of the church and to the discipline of religious persons. Their origin is to be found in the first years of Christianity, when the Christians made every effort to settle their disputes among themselves and to maintain their discipline without resorting to the courts presided over by pagan officials. These primitive Christian courts developed around the bishops, who came to take cognizance of all causes, temporal as well as spiritual, among the brethren. Later still, certain matters were assigned to them as proper causes for their especial jurisdiction, such as questions of taxation for the support of religion and matrimonial and testamentary causes. The character and extent of the jurisdiction of ecclesiastical courts must of necessity depend upon the relation existing between a state and the religious bodies within it. See ESTABLISHMENTS, ECCLESIASTICAL.

According to the leading authorities in this matter, no separate ecclesiastical courts existed in England before the Norman Conquest, as all causes, both civil and spiritual, were heard in the single county court, in which the bishop and the earl sat together. By a charter of William I a distinction was made between courts civil and courts ecclesiastical, and authority was given to the bishops to hear ecclesiastical causes according to the canon law, which was imported from the Continent. The extent of the jurisdiction of these ecclesiastical courts became a chronic source of dispute between the English crown and the see of Rome, until the jurisdiction of the Bishop of Rome was completely excluded by Henry VIII.

The ecclesiastical courts of England now consist of the following: the Archdeacon's Consistory, Peculiars, Arches Court, and, in cases of appeal only, the Crown in Council. The Public Worship Regulation Act of 1874 created a new ecclesiastical judgeship, having jurisdiction mainly of offenses in matters of ritual. In 1857 the greater part of the ancient jurisdiction of the ecclesiastical courts was taken away, and it is now vested in the Probate, Divorce, and Admiralty divisions of the High Court of Justice. They have, however, still to deal with questions of church government and discipline and changes in church buildings. If they in any manner exceed the limits of their jurisdiction, they are "prohibited" by the High Court of Justice. The power of the ecclesiastical courts over the laity is now practically obsolete. The decrees of these courts are enforced by suspension, deprivation, degradation, and by imprisonment under a writ *de contumace capiendo*. In the Isle of Man the ecclesiastical courts still have, as they formerly had in England, jurisdiction in probate and matrimonial causes. In Scotland the chief ecclesiastical courts have been the General Assembly, the Commissary Court, and the Court of Teinds. The first is the highest tribunal for the consideration of questions of doctrine and discipline according to the Presbyterian usage of the Established church. The courts of the American church bodies are considered under the various denominational titles.

ECCLESIASTICAL TITLES ASSUMP-

TION ACT. An act of the Parliament of Great Britain for the protection of the Established church of England. In the year 1850 an edict was issued by Pope Pius IX., dividing Great Britain into territorial bishoprics under an archbishop of Westminster. This brief was immediately followed by a pastoral letter by the newly appointed Archbishop, Cardinal Wiseman. This created much popular protest, and at the commencement of the parliamentary session of 1851 was spoken of as a papal aggression, and the necessary measures to counteract it became the chief topics of discussion. It was under these circumstances that Lord John Russell introduced the Ecclesiastical Titles Bill. By a previous act it had been provided that the right and title of archbishops to their respective provinces, of bishops to their sees, and of deans to their deaneries, as well in England as in Ireland, having been settled and established by law, any person, other than the person thereto entitled, who should assume or use the name, style, or title of archbishop of any province, bishop of any bishopric, dean of any deanery, in England or Ireland, should for every such offense forfeit £100. The Roman Catholics claimed that this enactment struck only at the titles of existing provinces and dioceses, and that, while the Pope could not create an archbishop of Canterbury, there was no prohibition against the creation of an archbishop of Westminster. To meet this claim and to remove the doubt that existed, the Ecclesiastical Titles Assumption Act was passed, its object being to prohibit the assumption of such titles "in respect of any places within the United Kingdom." The Catholics always considered the penal clauses of this act to be a grievance, and in time an arrangement was made for its repeal. An act was passed which, after declaring that "no ecclesiastical title of honor or dignity derived from any see, province, diocese, or deanery recognized by law, or from any city, town, place, or territory within this realm, can be validly created," and that no "preëminence or coercive power can be conferred otherwise than under the authority of her Majesty," repealed the Ecclesiastical Titles Assumption Act as inexpedient. The result is that, while no prosecution can now be had for assuming such titles, this assumption is still treated by the law as an illegal act. Practically, however, the law is a dead letter.

ECCELESIASTICAL TREATY RIGHTS.

See TREATY RIGHTS, ECCELESIASTICAL.

ECCELESIASTICUS, êk-klē-zī-ās'ti-kūs (Lat., from Gk. ἐκκλησιαστικός, *ekklesiastikos*, relating to an assembly, from ἐκκλησία, *ekklesia*, assembly). The Latin title of a biblical book called, in the Greek version, *The Wisdom of Jesus the Son of Sirach*, and, in the original Hebrew, sometimes *The Wisdom of Ben Sirā*, sometimes *The Proverbs of Ben Sirā*. Books read in public or regarded as suitable for that purpose and therefore kept in places of assembly were designated as *libri ecclesiastici*, or 'church books,' by the Latin Christians. When, largely through the influence of Jerome, books found in the Greek Bible, but not in the generally recognized Hebrew canon, began to be looked upon as only deuterocanonical, or even apocryphal, the term "church books" was not improperly confined to the works still read and cherished by the church, though rejected by the synagogue. Among these, *The Wisdom of Jesus the Son of Sirach*, being used as a textbook

in the instruction of catechumens, naturally became known as the "church book" par excellence; hence the name *Eccelesiasticus*. The Hebrew original was widely read as a holy book in the days

of the canon. (See title of *the Bible*, in the article BIBLE.) So strongly was it intrenched that, even after the canon had been reduced to 22 or 24 books, it still continued to be used and quoted as Scripture, particularly by the rabbis of Sora. Patristic and mediæval writers, who, on the ground of its absence in the Hebrew Bible, regarded it as canonical only in a secondary degree, freely appealed to its authority in support of doctrine. Its canonicity was rejected by the Reformers, though it was still printed in their versions.

Until 1896 the Hebrew original was known only through quotations in rabbinic literature. Of these there were about 80, amounting to perhaps one-twentieth of the entire text. Since the year mentioned, fragments of four manuscripts have been discovered. All of these have come from the *geniza*, or hiding place for worn-out copies of biblical books and esoteric or forbidden works in the synagogue of Cairo. They cover about four-fifths of the book and furnish in some instances two or three witnesses to the text. Numerous marginal notes also supply variant readings and doublets. Probably no one of the manuscripts is older than the eleventh century. One was evidently made by a Persian Jew, who occasionally put into the margin remarks in his own vernacular. There can be no reasonable doubt that all these manuscripts in the main represent the Hebrew original. But it is equally manifest that the text has been greatly corrupted, and in some cases has been corrected, or at least shaped, under the influence of either the Syriac version itself or an Aramaic targum closely resembling it. The ancient versions therefore remain of utmost importance. Of these, the Greek and the Syriac were made directly from the Hebrew; the Latin, the Syro-Hexaplaric, the Ethiopic, and the Coptic are the chief translations of the Greek. A prologue to the Greek version states that the author's grandson, who translated the work, came to Egypt in the thirty-eighth year of King Euergetes. This can only be Ptolemy Euergetes II, called Physcon, who was the only Euergetes reigning as long as 38 years; the years of his reign are counted from the time when he first assumed power in 170 B.C. Hart has attempted to prove that Physcon was so hostile to the Jews that no Jew would have thought of coming to Egypt in his reign and that the grandson of Ben Sirā came to Egypt in the first year of Euergetes I, which was the 132nd year of Philadelphus, or 247 B.C. But his arguments are far from convincing; such a construction of the phrase "now in the thirty-eighth year under Euergetes" seems indeed impossible. How long after the year 132 B.C. Ben Sirā's grandson lived in Egypt before he was able to undertake the task of translating this book cannot be determined. But it is likely that the work was not completed until the time of Ptolemy Soter II, called Lathyrus, the first period of whose reign extended from 117 to 106 B.C. Another prologue of uncertain authority printed in the editio princeps, the Complutensian Polyglot, may not be older than the fourth century A.D. and draws its information from the work itself. Not even its independent statement that

the translator's name was Jesus can be accepted on so doubtful authority. We are far from possessing the original of this translation. The text presented by the great uncial codices is much inferior to that followed by a group of cursives and one late uncial. Particularly the manuscript printed in the Complutensian has preserved an older and better text. Yet no codex has suffered more by interpolations than this very one. A curious displacement is found in all manuscripts. Without a single exception they pass from xxx. 24 to xxxiii. 16, continue to xxxvi. 11, and then go back to the section xxx. 25-xxxiii. 15. This could not well have found its way into all manuscripts except through the authority and influence of some universal codex. It is difficult to avoid the conclusion that this was Origen's Hexapla. The fact that the Syriac version of Paul of Tella uses the asterisk and obelus to indicate differences from some recognized original, renders it possible that Origen actually compared the Greek text of his book with a Hebrew copy. The displacement may have taken place before his time, and a different arrangement of his small books forming the volume even in this Hebrew copy may have facilitated the error. In some places the Latin and in others the Ethiopic has preserved an earlier and better reading than that found in any manuscript. The Syriac version is a translation from the Hebrew. Its often starting with the recovered Hebrew text confirms this conclusion. But it is evident that here and there it has suffered corruption. Originally made in all probability by a Jew, it subsequently passed through many Christian hands that have left their mark. And occasionally its agreement with the Hebrew seems to be due to the influence it has itself exerted on the latter. Though the facilities for textual criticism have thus been greatly enriched, considerable uncertainty still exists as to the original.

By the discovery of the Hebrew text new questions have been raised as to the name of the author and the integrity of his work. The colophon (l. 27) designates as author Simeon, son of Jesus, son of Eleazar Ben Sira. The statement is repeated in chapter li, and also given in the abbreviated form, "Simeon, son of Jesus, who is called Ben Sira." Ben Sira is consequently the family name that might be added to the proper name of father and son alike. The best Greek manuscripts corroborate the statement that Eleazar was the name of the father of Jesus Ben Sira. If the Hebrew text is to be trusted, the authorship is consequently assigned, not to Jesus, but to his son Simeon. One of the editors also maintains that the name of the translator's grandfather was Simeon Ben Sira. But the name Jesus is too closely associated with the book, both in Jewish and Christian tradition—as the superscriptions, on the one hand, and the application to the author of the legends of the nativity, on the other, show—to permit such an assumption. Another solution suggests itself. Chapters xlv-1 once formed a separate book. It has been demonstrated that the old Latin version, which Jerome adopted without much emendation, was made by two different men, living in different lands; chaps. xlv-1 not having been translated by the same hand that produced the rest. The unity of this section and its distinct character render it natural that it should have circulated separately.

If that is the case, the colophon in l. 27 refers, not to the entire work, but to these chapters. Internal evidence renders it entirely probable that this part was written in the Hasmonean period, by the son of Jesus Ben Sira. The reference to a transfer of the high priesthood, and the promise of David to the posterity of Phinehas, because of his zeal, in xlv. 23-26, and the description of the high priest Simon in l. 1-24, seem quite decisive. It is natural that the assumption of the pontificate by the Hasmoneans should have been in need of scriptural support, and the reward promised to Phinehas for his zeal seems to have furnished the necessary prophecy. Scholars have been divided in regard to the identity of the Simon praised in chap. l. Some have thought of a high priest, Simon the Just, supposed to have lived in the beginning of the third century; others of a Simon who held the office a century later. There is no record showing that either of these men achieved any of the deeds for which Simon is lauded. If Simon the Just really lived in the time of Ptolemy Soter, and if this King's harsh treatment actually included the specific damage presupposed, the high priest may indeed have paid attention to the necessary repairs. But Josephus does not seem to have found any mention of this in his sources, since he is able to give no other reason for the title than Simon's piety towards God and kind disposition towards His people. His sources, however, appear to have been late and unreliable. Concerning the Simon who was high priest in the days of Antiochus III, Josephus has no information to give. As evidence of this King's kind feeling towards the Jews, he quotes a letter of his to Ptolemy, in which he tells the Egyptian King, from whom he has just taken Palestine, how generously he is about to reward the inhabitants of Jerusalem for their services in the war. But the letter is manifestly a forgery; and it is significant that Josephus can quote no act, but only a promise, to show the attitude of Antiochus. On the other hand, we know, from the colophon in xliii and xiv, that Simon, high priest, repaired the temple, fortified the holy hill after the capture of the tower, built walls, and strengthened the city against the enemy. The only feature of the description in Ecclesiasticus l not found in this source is the construction of a cistern; but if Simon filled up the hollow between the Akra and the temple north of it, he is quite likely also to have paid attention to the water supply. There is no reason to doubt the accuracy of the Hebrew colophon. Chapter li is made up of two parts—verses 1-12 and 13-29. The latter is an acrostic poem, each stichos beginning with a new letter of the alphabet. Between both, the Hebrew text has a long hymn, probably written in the second century A.D. The whole chapter is late. In the part of the book that in the main is the work of Jesus Ben Sira, the clear allusion to the death of Antiochus IV in x. 9, the acquaintance with Daniel and the whole tenor of the prayer in xxxvi. 1-17, and the fact that chap. xliii does not seem to have been extant in the Hebrew text used by the Syriac translator—apparently point out these sections as later interpolations. Concerning the time when Jesus Ben Sira lived we have no other evidence than the Greek translator's statement that the author was his grandfather. This would render it probable that he wrote his work between 190 and 170 B.C. In

his theological views he occupies substantially the position of the later Sadducees. When he meets with angels in a biblical passage, he gets rid of them by a rationalistic interpretation. He recognizes no demons. He never hints at any Messianic hope. He is convinced that "the son of man is not immortal." He honors the law, reveals its meaning, but knows as yet no canon of its interpretation. He feels that he is himself raised up to be a teacher, even as the holy men of old. His moral teaching is utilitarian and individualistic. His aim is the happiness that a certain line of conduct will bring. The welfare of others is not presented as a consideration. The author lays down rules rather than principles. He directs how men should act in different situations. His work is not so much a conscious endeavor to find a basis for morality outside of religion, as rather an earnest attempt to commend the righteous life for the happiness it brings to the wisdom-seeking youth of his time.

ECCLESIAZUSÆ (Lat., from Gk. ἐκκλησιαζουσαι, *ekklesiázousai*, women in assembly). An inferior comedy by Aristophanes, produced 392 B.C. His subject is an imaginary national assembly of women, held for the establishment of women's rights, socialism, etc., at Athens. The play is aimed at the attempts to restore the state by means of formal constitutions. See **ARISTOPHANES**.

ECCLESIOLOGY (from Gk. ἐκκλησία, *ekklesiá*, church + Gk. λογία, *logia*, account, from λέγειν, *legein*, to say). 1. That branch of the general science of human society or sociology which deals with so much of human relations as exist for the purpose of religion, embracing the analysis of the church as organized society, its constructive principles (see **POLITY**), its relations to the other organizations of society, such as the state, the features of its internal law, and the sphere of its discipline. As con-

structive principles, it considers Episcopacy and Papacy, Presbyterianism, Congregationalism, etc. (qq.v.). 2. The term also connotes that branch of antiquities which deals with the building in which this organized society meets, the church as a structure, and its decoration. It takes note of ecclesiastical architecture, not from the point of view of art history, but from that of its relation to liturgy and ceremonial, iconography, the customs regarding clergy and congregation. It explains the ground plan, elevation, orientation, internal divisions of the church: the form and position of crypt, confessional, altar, lectern and pulpit, choir and choir screen, seats for clergy, books and vessels for sacred service, priestly robes, paschal candlesticks, reliquaries, crosses, croziers, tabernacles for holy oils, holy-water vase, and other church furniture; it also treats of the baptistery, baptismal font, and chrismatory; of the belfry, its bells, chimes, windows; of the chapels, porches, and other subordinate structures. See **CHURCH**; **BASILICA**; **CATHEDRAL**; **TOWER**; **MONASTIC ART**; the separate articles on parts of the church and on articles of church furniture.

Bibliography. Rohault de Fleury, *La messe* (Paris, 1883-89), is the fullest systematic study of church furniture; the articles scattered through Smith and Cheetham's *Dictionary of Christian Antiquities* (London, 1877-87) are excellent synopses for the period ending with the early Middle Ages. Durand, a bishop of the thirteenth century, wrote a manual of ecclesiology called *Rationale Divinorum Officiorum* (many editions, and an English translation with an essay by Neale and Webb, "The Symbolism of Churches and Church Ornaments," New York, 1893). Pöhlmann, *Altchristliche Architektur* (Stuttgart, 1881), gives the links between liturgy and church architecture and furniture of the early period. Consult also: Andrews, *Curious Church Customs* (Hull, 1895); Bumpus, *A Dictionary of Ecclesiastical Terms* (London, 1910); Lee, *Glossary of Liturgical and Ecclesiastical Terms* (ib., 1877); Ducange, *Glossarium*.

EC'CLESTON, SAMUEL (1801-51). An American Roman Catholic clergyman. He was born in Kent Co., Md., and studied at St. Mary's College, Baltimore, of which he became president in 1829. In 1834 he succeeded Dr. Whitfield as Archbishop. Under his auspices the Christian Brothers established a novitiate and training school of their order, parochial schools were multiplied, and several academies for girls were established under the Nuns of the Visitation.

E CHANG. See **I CHANG**.

ECHEGARAY, a'chá-gá-rí', José (1833-1905). A Spanish playwright, scientist, and philosopher, born in Madrid. He received a professional education in mathematics at the school of engineering. He was Minister of Public Instruction in 1873 and Minister of Finance in 1874 and 1905. In 1874 his plays *El libro talonario* and *La esposa del vengador* marked the beginning of a splendid dramatic career for himself and the opening of a new epoch in the history of the Spanish stage. He wrote, all told, some 70 plays in verse and prose. His tone is one of almost uniform gloom, relieved, however, by the presence of a sane belief in the

efficacy of moral law and by a splendid idealism. His principal plays are: *En el puño de la espada* (1875); *Ó locura ó santidad* (1876); *En el seno de la muerte* (1879); *El gran Galeoto* (1881), treating of the power of slander and considered his best work; *Vida alegre y muerte triste* (1885); *Mariana* (1892); *El hijo de Don Juan* (1892), based on, and identical in theme with, Ibsen's *Ghosts*; *El estigma* (1895); *La duda* (1898); *El loco Dios* (1900); *La escalinata de un trono* (1903); *La desequilibrada* (1903); *A fuerza de arrastrarse* (1905). In 1904 he shared with Mistral the Nobel prize for literature. Americans are familiar with *El gran Galeoto* not only through Charles Frederick Nirdlinger's translation, but through the stage production by Mr. and Mrs. William Faversham, under the title "The World and his Wife." Three other works have also appeared in English translation: *El loco Dios*, as *The Madman Divine*, by E. H. West (in *Poet Lore*, vol. xix, 1908); *Ó locura ó santidad*, as *Madman or Saint*, by Ruth Lansing (in *Poet Lore*, vol. xxiv, 1912); and *Mariana* (New York, 1914). Consult: A. Zacher, *Don José Echegaray, Der Verfasser des Galeoto* (Berlin, 1892). F. Vézinet, *Les maîtres du roman espagnol* (Paris, 1907); L. Antón del Olmet and A. García Caraffa, *Echegaray* (Madrid, 1912); H. de Curzon, *Le théâtre de José Echegaray* (Paris, 1912).

ECHELON, ɛsh'e-lŏn (Fr., round of a ladder, from *échelle*, OF. *eschelle*, ladder, from *lascala*, ladder) A military formation. A regiment, when ordered to advance in echelon, would proceed as follows: The leading or named company would advance, followed at company distance by the remainder of the regiment, each marching in a direction parallel to its front, so that, if the leading company were to halt, the remainder would return to the original line formation. The echelon formation is used because of the facility with which "line" may be formed in any direction—front, flank, or rear; it also presents certain obstacles to accurately sighted rifle fire from the enemy. The word "echelon" is also sometimes used, in a broader sense, to designate the subdivisions in rear of the advance element of a large organization or system of supply; e.g., the ammunition supply of the firing battery is usually obtained from the echelons in rear in the following order: combat train, ammunition column, line of communication trains, advance-supply depot.

ECHENEIS, ɛk'ɛ-nɛ'is, **ECHENEIDIDÆ**, ɛk'ɛ-nɛ'id'id-ɛ. See REMORA.

ECHENIQUE, ɛ'chā-nɛ'kā, JOSÉ RIVERO (1808-87). A Peruvian soldier and statesman, born at Puno. When the army under Gamarra and Bermudez revolted, in 1833, he restored order, and later fought in the cause of Santa Cruz and the confederation, but made his peace with Gamarra. In 1846 he became a member of Castilla's council. He was elected President of Peru, April 20, 1851. His administration was remarkable in many ways. He undertook more public works than any of his predecessors and did more than they for the spread of public instruction. And despite all that, he was able, in 1853, to show a balance of 3,000,000 pesos in the budget. He instituted important reforms in the management of the public debt, restoring the nation's credit both at home and abroad. He negotiated important

treaties with several European nations. Despite the perilous times in which he lived and the practices of many other statesmen of his day, he never had recourse to the death penalty. He remained in office until 1855, when repeated revolts against his authority, culminating in his defeat by Castilla, resulted in his banishment from the country. Returning in 1862, he was at once elected deputy, and in 1864 President of the Chamber. Later he was elected senator and became President of the Senate. He aided in the defense of Callao during the Spanish War of 1866. His candidacy for the presidency in 1872 was not successful.

ECHEVERRÍA, ɛ'chā-vɛr'ɛ'á. ESTÉBAN (1809-51). A South American poet, born at Buenos Aires. His education was French, and his early works showed that influence, but he afterward became more national, and his poem *La cautiva* (1837) contains fine descriptions of the pampas. He was exiled by the Dictator Rosas and went to Montevideo, where he died. His complete works were published at Buenos Aires in 1874, in 5 vols., under the direction of Juan María Gutiérrez, an Argentine man of letters.

ÉCHEVIN, ɛsh'vān' (OF., Fr. *eschevin*, It. *schiafino*, *scabino*, from ML. *scabinus*, sheriff, from OHG. *skæffino*, Ger. *Schoffe*, from OHG. *scaffan*, Ger. *schaffen*, to create). During the early Middle Ages, a royal officer possessing a large measure of power in local administration. The office was common in France and the Low Countries and prevailed to a less degree throughout Germany. It first appears in the documents of the eighth century. When Charles the Great reformed the administration, the *échevins* became royal officers for the counties and hundreds. They were named by the *missi*, or royal deputies, the counts, and the people, and held their office during good behavior. The system continued without any important change during the Carolingian period. In the tenth century the *échevins* were given jurisdiction over the nonnoble class, the peasants, and the towns, and later became municipal magistrates. At the close of the twelfth century the *échevins* in the towns were elected yearly. The *échevins* seem to have formed a body or tribunal which in many cases not only administered justice, but controlled military affairs and imposed police regulations. In the north of France these tribunals were especially numerous. The powers of the *échevins* declined after the sixteenth century, and the central government, in 1764, sought to unify the whole system of *échevinage* by limiting the number to four for all large towns. In Paris there were four *échevins*, two chosen each year. Their powers were limited to the regulation of trade, fixing the prices of commodities, and settling the disputes of tradesmen. The office of *échevin* was abolished in December, 1789, during the first period of the French Revolution. The title is now used in Belgium for an assistant to the burgomaster. Consult Cheruel, *Dictionnaire historique des institutions, mœurs, et coutumes de la France*, vol. i (Paris, 1874).

ECHIDNA, ɛ-kid'nā (Lat., Gk. *ἐχίδνα*, viper, from *ἐχis*, *echis*. Skt. *ahi*, Av. *achi*, serpent). A genus and family (Echidnidae) of monotreme mammals, the spiny or porcupine anteaters of the Australian region, closely allied to the duck-bill. The ordinary echidna is from 12 to 18

inches long and has a broad, depressed body, mounted upon very short, strong legs terminating in big, powerful claws suited to digging into hard ground. The head is small, and the nose prolonged into a slender snout; the mouth

AUSTRALIAN SPINY ANTEATER.
(*Echidna aculeata*.)

is without teeth, but the palate is studded with recurved spines, and the tongue is slender, extensile, and glutinous. The back of the animal is covered with stiff, hedgehog-like spines, mixed with long, coarse hairs; and when danger threatens it outside its burrow, it curls up much like a hedgehog, so as to protect the under parts, which have no spines, but are clothed in silky brown hair. The males have spurs on their heels, like the duckbill (q.v.), but have never been seen to use them. It dwells in burrows of its own digging and obtains its food by excavating in the hillocks of ants, which it tears open in order to devour the succulent larvæ. Like other monotremes, the echidnas lay eggs. After a period of gestation of 27 or 28 days one or two eggs are laid, and one is placed in the temporary pouch, where after about two weeks it hatches. The young echidna is carried in the pouch until fairly good-sized and able to walk. They are gentle in disposition, endure confinement well, eating bread and milk, chopped eggs, etc., and are frequently kept as intelligent and playful pets, exhibiting a good deal of activity and agility. They are inclined to nocturnal habits and in times of drought become dormant in their burrows.

The common echidna (*Echidna aculeata*) seems to be very variable in size, color, and length of spines, and some naturalists have separated the large Tasmanian form as *Echidna setosa*, and the small New Guinea form as *Echidna laurssii*, but their specific value is doubtful. In New Guinea there also occurs a closely related animal, *Proechidna* (or *Acanthoglossus*)

THREE-TOED PAPUAN ANTEATER.
(*Proechidna bruijnii*.)

bruijnii, which is much larger, has only three claws on each foot, and its snout and tongue are greatly prolonged. The Papuans call them nodiaks, and hunt them for food in the Arfak Mountains by the aid of dogs which know how to dislodge them from their burrows. Consult: Bennett, *Gatherings of a Naturalist in Australia* (London, 1860); Saville-Kent, *The Naturalist in Australia* (ib., 1897); Lucas and Souëf,

Animals of Australia (Melbourne, 1909); English, *The Sphere*, vol. liv (London, 1913). See MONOTREME.

ECHINADES, ê-kin'à-dêz (Lat., Gk. Ἐχινάδες, from ἔχινος, *echinos*, hedgehog). A group of islands in the Ionian Sea, now known as the Kurzolari Islands. They are situated around the entrance of the Gulf of Corinth and are supposed to have been formed by drift from the river Achelous. Off these islands was fought the celebrated battle of Lepanto in which Admiral Doria and Don John of Austria overwhelmed the Turkish fleet under Ali Pasha (Oct. 7, 1571).

ECHINIDÆ, ê-kin'î-dê. See SEA URCHIN.

ECHINOCARIS, ê-kî'nô-kâ'rîs (Neo-Lat., from Gk. ἔχινος, *echinos*, hedgehog + *karis*, *karis*, shrimp). A fossil crustacean, the tail spines of which are common in certain Devonian rocks. See PHYLLOPODA.

ECHINOCOCCUS, ê-kî'nô-kôk'kûs. See TAPEWORM.

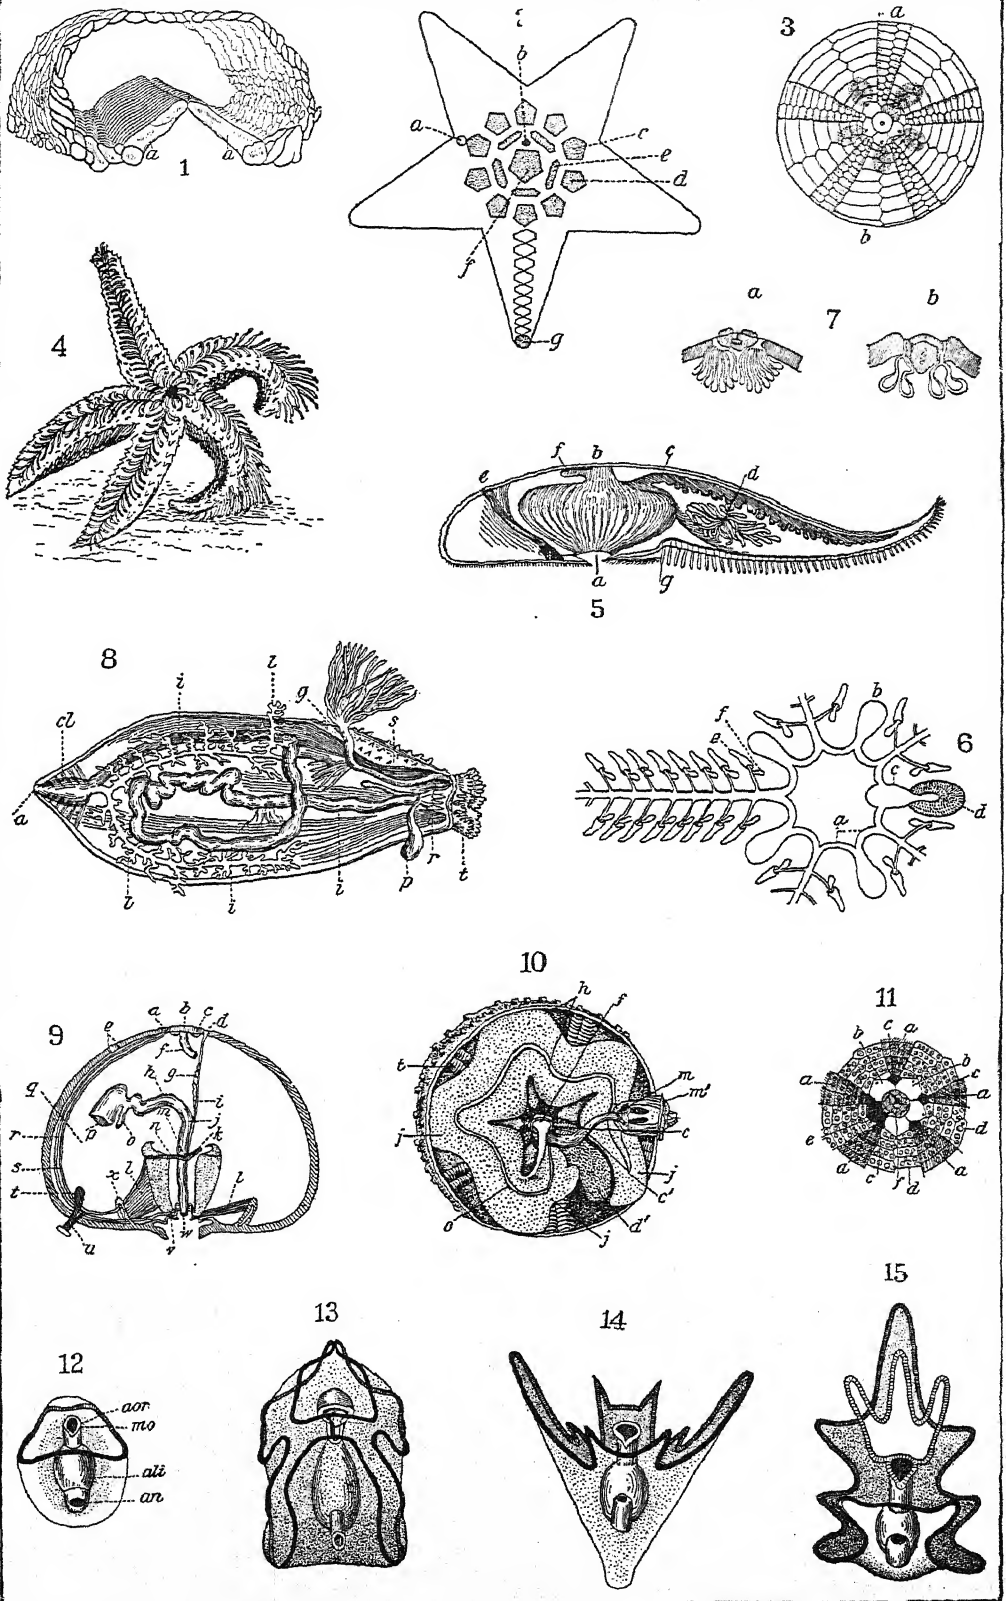

ECHINOCONUS, ê-kî'nô-kô'nûs (Neo-Lat., from Gk. ἔχινος, *echinos*, hedgehog + *kônos*, *kônos*, a cone). A genus of large, conical, or subhemispherical echinoids with flat actinal region and sunken peristome, found abundantly in the Lower and Middle Cretaceous rocks. See ECHINODERMATA; ECHINOIDEA.

ECHINODERMATA, ê-kî'nô-dêr'mâ-tâ (Neo-Lat. nom. pl., from Gk. ἔχινος, *echinos*, hedgehog + *derma*, *derma*, skin). One of the great branches or phyla of invertebrate animals, constituting an independent, well-characterized assemblage of organisms. The group is of higher rank than the Cœlenterata and is lower than the Vermes, with both of which groups it has few features in common. The animals of this phylum do not reproduce by either budding or

EXPLANATION OF THE PLATE OF ECHINODERMATA.

1. Section of the ray of starfish, showing structure of the skeleton: *a*, *a*, ambulacral ossicles, between which lies the ambulacral vessel in the ambulacral groove. 2. Aboral plates of a starfish: *a*, madreporite; *b*, anus; *c*, one of the five basal plates; *d*, one of the five radials; *e*, circle of secondary radials; *f*, dorsocentral; *g*, terminal or ocular plate (cf. Plate of CRINOIDS, Fig. 7). 3. Aboral view of a sea urchin, stripped of epidermis: *a*, ambulacral plates, in five zones; *b*, plates of interambulacral zone. 4. Tube feet of a starfish, as used in turning the body over. 5. Section of the disk and arm of a starfish: *a*, mouth, leading into the wide stomach; *b*, anus; *c*, hepatic prolongation of the stomach into the cavity of the arm; *d*, genital organs; *e*, madreporic plate (opening of madreporic or stone canal); *f*, interradial diverticulum of the rectum; *g*, ambulacral feet. 6. Diagram of the water-vascular system of a starfish: *a*, oval circular vessel; *b*, one of the ampullæ or Polian vesicles; *c*, stone canal; *d*, madreporic plate; *e*, one of the series of ambulacral feet connected with the side twigs of the radial canal; *f*, one of the ampullæ of the same. 7. Transverse sections of the ambulacral fields of two blastoids, showing forms of hydrospires: *a*, Orophocrinus; *b*, Granatocrinus. 8. Anatomy of a holothurian: *t*, tentacles; *r*, calcareous ring at the base of the tentacles; *p*, Polian vesicle; *s*, sand canal; *i*, *i*, alimentary canal; *g*, duct of the reproductive organs; *cl*, cloaca; *a*, anus; *l*, *l*, respiratory tree. 9. Vertical section of an echinoid (sea urchin): *a*, ocular plate; *b*, anus; *c*, aboral ring blood vessel; *d*, madreporite; *e*, radial extension of the stomach, surrounding the radial nerve; *f*, rectum; *g*, ovoid gland; *h*, intestinal blood vessel; *i*, stone canal; *j*, alimentary canal; *k*, Polian vesicle; *l*, *l*, muscles passing from the auricles to Aristotle's lantern; *m*, oral ring blood vessel; *n*, radial ambulacral vessel; *o*, siphon; *p*, intestine; *q*, cœlome; *r*, radial nerve; *s*, radial ambulacral vessel; *t*, ampullæ; *u*, ambulacral feet; *v*, radial nerve; *w*, mouth; *x*, auricle. 10. Horizontal section of a sea urchin, showing organs (letters as in Fig. 9); also, *c*, œsophagus; *d'*, ovary; *m'*, Aristotle's lantern. 11. Apical system of plates and aboral extremities of zones of the shell of a sea urchin: *a*, ambulacral zones; *b*, genital plates; *c*, (black) ocular plates; *d*, interambulacral zones; *e*, madreporite; *f*, periproct. 12-15. Diagrams of the development of the larvæ of echinoderms: 12, primitive form; 13, auricularia (holothurians); 14, a pluteus (sea urchins and brittle stars); 15, a bipinnaria (starfishes).

ECHINODERMATA

fission, and therefore they are never found in compact colonies like those formed by the coelenterates. The body of the animal is built, more or less constantly throughout the phylum, on the pentamerous plan of bilateral symmetry, in accordance with which the number five is a dominant feature in the arrangement of the parts.

External Covering. The external covering of the echinoderms is remarkable for its diversity, for even within the limits of the same family we find a soft, leathery body wall at one extreme and a firm, almost immovable "shell" at the other. This diversity is entirely due to the amount of mineral matter deposited in the body wall and the plates formed from it. In the body wall is chiefly composed of connective tissue, within which are deposited disconnected particles of lime, while in most sea urchins there is little connective tissue and the carbonate of lime is deposited in firm plates of definite size and shape firmly welded into a hard shell, or "test," as it is commonly called. This external covering usually functions quite as much as a skeleton for the attachment of muscles as it does as a "shell" for protection. The body wall is often covered with more or less evident knobs, tubercles, or spines, and from the frequency of the latter has arisen the name "spiny-skinned" animals. These knobs and spines are attached to the plates of the skeleton, either immovably or by a joint which permits of perfect freedom of movement.

Visceral Anatomy. There is a well-developed alimentary canal, and distinct from the general body cavity, or coelome, and provided with both mouth and anus, though the latter may be more or less suppressed in some groups. A combined respiratory and locomotory system of complicated nature, called the water-vascular system, is peculiar to the members of this phylum only. A nervous system, blood-vascular system, and reproductive system are more or less fully developed.

The nervous system is variously modified in the different classes of echinoderms. In all there is a well-developed epidermal system, with circumoral ring and radial branches.

Sense organs are few and imperfect. We find occasionally pigment eyes, ciliated pits (perhaps olfactory), and positional organs. The sense of touch is well developed. The blood system is rarely developed, though many forms have an "axial organ and strands," the anatomy and physiology of which are still little understood. Special respiratory and excretory organs are found in a few cases.

The water-vascular system, which is present in more or less complete form in all members of the group, consists of a ring vessel about the mouth. From this ring vessel a number of tubes, generally five, radiate to the ambulacral areas, or "radia." These tubes connect with the "tube feet," or ambulacra, which are extensible sac-like tentacles that project from the surface of the body through pores in the plates of the ambulacral areas. These tube feet function not alone as locomotory organs, but also as respiratory organs, and in some classes they assist in conveying food to the mouth. The circumoral ring vessel has communication with the outside, in most echinoderms, through a tube of variable form, called the stone canal or madreporic canal, which extends from the ring vessel to a special plate, the madreporic plate, on the

aboral side of the body. This plate is sieve-like, and through it is sucked the water that fills the water-vascular system. Connected with the ring vessel, in all classes except the Crinoidea, are peculiar bladder-like organs, the Polian vesicles, that serve to regulate the pressure in the radial tubes. Lack of active locomotion obviates the necessity for a well-developed muscular system, although some special muscles of complicated nature are present in connection with particular organs, as the jaws of echinoids.

The mouth of echinoderms is sometimes, especially in the Holothuroidea, surrounded by a crown of tentacles. Usually it is a simple opening, but in the Echinoidea (sea urchins) it is provided with a complex system of jaws that form the so-called "Aristotle's lantern." Outgrowths from the alimentary canal, called "respiratory trees," found in the holothurians, and an accessory intestine, attached to the intestine proper in the echinoids, and other modifications of various organs, constitute the respiratory organs; there are no strictly special respiratory organs in the members of this branch.

The sexes are separate, and development takes place through metamorphosis. The egg produces a bilaterally symmetrical free-swimming larva, which differs somewhat in form in the different classes. Three types of larva have been distinguished, and they have received the names auricularia, bipinnaria, and pluteus.

Ecology. About 3000 living echinoderms are known. They are all marine, and the species are scattered throughout all seas of the globe and are found at all depths, but they are most abundant in the warm seas of the tropics. The only fixed members of the branch are those included in the subbranch Pelmatozoa, comprising the crinoids, cystoids, and blastoids. Many echinoderms, especially the crinoids, are gregarious, and they are found associated together in vast numbers. Echinoderms are largely benthonic organisms, crawling slowly on the bottom of the sea by means of the tube feet or arms, as in the starfish and sea urchins, or by the oral tentacles, as in holothurians. The fixed pelmatozoans are either benthonic, when fixed to the bottom, or pseudoplanktonic, when attached to floating wood, and the free-swimming crinoids almost all among the pelagic animals or plankton.

Classification. The Echinodermata are divided among the following seven classes: Holothuroidea, Echinoidea, Asteroidea, Ophiuroidea, Crinoidea, Cystoidea, and Blastoida. The last three groups, comprising mostly attached forms, are often included as subclasses under a class Pelmatozoa. We prefer to associate the first four in a subbranch Eleutherozoa, and the last three in a second subbranch, Pelmatozoa. The characters of the various classes are as follows:

I. **HOLOTHUROIDEA** (holothurians, or sea cucumbers). The body is cylindrical or wormlike, and has a soft leathery skin, in which are imbedded minute calcareous spicules or plates. A certain degree of bilateral symmetry is apparent, but there is little trace of radial pentamerous symmetry. The mouth is at the anterior end of the body and is surrounded by tentacles; the anus is at the posterior end. The only portions of holothurians that are apt to be preserved as fossils are the calcareous bodies of the skin. These are known in rocks of Carboniferous to

recent time, but they are never common. See HOLOTHURIAN.

II. ECHINOIDEA (sea urchins). In this group the body is inclosed in a more or less rigid box of polygonal stony plates, arranged in rows that form five ambulacral and five interambulacral areas. In the more regular, radial forms both the mouth and the anus are central on opposite surfaces of the body. In other irregular forms, exhibiting less radial and greater bilateral symmetry, the mouth may be placed towards the anterior end and the anus is variously situated, either on the dorsal, lateral, or ventral surface, but always in the middle line. The majority of echinoids have complicated jaws. About 300 living and 2500 fossil species are known. The earliest appear in Ordovician rocks. See ECHINOIDEA; SEA URCHIN.

III. ASTEROIDEA (starfish). The bodies of the animals of this class are flattened dorsoventrally, and the ambulacra are produced into five (or some multiple of five) radiating arms. The arms are not at all demarcated from the central portion of the body, and they contain prolongations of the coelome and of most of the organs. Radial symmetry is quite marked. The tough skin contains calcareous plates of irregular form that are not united to each other, so that the body wall is to some extent flexible. The ambulacral plates occupy the larger portion of the undersides of the arms, and the tube feet are well developed. The large mouth opening is in the center of the ventral surface of the disk, and the small anal opening is near the centre of the dorsal surface, except in a few genera, where it is wanting, and the intestine is then closed. The earliest starfish appear in rocks of Ordovician age, and they have continued, though never becoming abundant, through all subsequent periods down to the present. See STARFISH.

IV. OPHUROIDEA (brittle stars). The animals of this group have the body flattened in the same manner as in the Asteroidea, with the ambulacral arms produced into five long rays that are either simple or many times branched. The body is covered by stony plates that present a greater degree of systematic arrangement than is seen in the Asteroidea, and they are more firmly united. The central disk is well demarcated from the arms, and no portions of the coelomic cavity or diverticula of the alimentary canal or genital system are prolonged into them. The arms serve for locomotion. The mouth is central on the ventral surface, and the anus is closed. The class makes its first appearance in Silurian rocks, and it is represented, though rarely, in rocks of all later periods. At present its members are widely distributed. See OPHUROIDEA; BASKET FISH; BRITTLE STAR.

The subbranch Pelmatozoa, including the Crinoidea, Cystoidea, and Blastoidea, constitutes a group of mostly attached echinoderms in which the body is inclosed in a somewhat cup-shaped, spherical, or saclike box of calcareous plates, and is raised, during at least a portion of the life of the individual, upon a stalk with the ventral surface and mouth upward.

V. CRINOIDEA (sea lilies). These are pelmatozoans in which the cup-shaped body wall is made up of closely joined plates arranged according to definite plans of pentamerous radial symmetry, the arrangement varying in every family according to the number of plates in the "calyx," or body cup. The calyx bears five simple or branched, highly flexible arms, that are pro-

vided with pinnules to screen food from the water. The mouth is at the middle of the upper or ventral surface, and the anus is excentric. Both these orifices undergo peculiar and important modifications that are used in classifying the members of the group. The class appeared in Ordovician time and was exceedingly abundant during the Paleozoic era. About 2000 fossil species, in 175 genera, and 600 living species are known. See CRINOIDEA.

VI. CYSTOIDEA. Pelmatozoans with spherical or saclike body inclosed in a more or less irregular box, composed of more or less closely united polygonal plates that present definite plans of arrangement only in the most advanced forms. The animals were sessile, stalked, or free. The arms are poorly developed and in some forms are not separated from the oral surface of the body, in which case they appear as ambulacral grooves radiating from the mouth. The mouth is central, and the anus is always excentric and is placed either on the oral or aboral surface. In some forms the mouth is slightly excentric. The earlier and more primitive members of the class are spherical, with the plates very irregular. There are some genera which exhibit tendencies towards the crinoid type; others resemble the blastoids or the echinoids, or starfish. On this account the cystoids have by some authors been considered to resemble, more nearly than any other class, if not actually to represent, the original primitive echinoderm stock from which were derived through evolution all the other classes. Cystoids appear in the rocks of Upper Cambrian age, being the earliest group of echinoderms, and they reached a considerable expansion in the Ordovician and Silurian periods. They disappeared at the close of the Paleozoic. See CYSTOIDEA.

VII. BATHYURIDEA (Pentremites). This is a small, extinct, specialized group of echinoderms, derived from the cystoids at perhaps an early Ordovician date, that did not reach its maximum development until Carboniferous time. Then, however, after the cystoids had quite disappeared, and the crinoids had begun to decline, the bathyurids attained considerable prominence, so that their members are characteristic index fossils of the Carboniferous and Permian rocks. The class became extinct at the close of the Paleozoic. The body is inclosed in a bud-formed box made up generally of 13 plates of regular form and strictly pentamerous radial arrangement. The mouth is at the summit of the calyx, and the anus at the side. There are no arms, and the relatively large ambulacral areas extend downward over the surface of the calyx, sometimes nearly to the base or stem. The stem was short or absent. About 20 genera and 150 species are known. See PENTREMITES.

Bibliography. For general treatises on both living and fossil forms, see Bather, "The Echinoderma," in Lankester's *Treatise on Zoology*, part ii (London, 1900); this contains a good bibliography. Consult also: Parker and Haswell, *Textbook of Zoology*, vol. i (London and New York, 1910); Lang and Bernard, *Text-Book of Comparative Anatomy*, part ii (ib., 1896), also with a bibliography. These last two works are technical. Zittel and Eastman, *Text-Book of Paleontology*, vol. i (ib., 2d ed., 1913), deals almost entirely with the fossil forms. Consult also: Alexander Agassiz, "Paleontological and Embryological Development," *Proceedings of the*

American Association for the Advancement of Science, Boston Meeting (Cambridge, 1880); Carpenter, "Notes on Echinoderm Morphology," *Quarterly Journal of the Microscopical Society*, N. S., vols. xviii-xxviii (London, 1878-87); Bell, "On the Arrangements and Interrelations of the Classes of the Echinodermata," *Annals and Magazine of Natural History*, series vi, vol. vii (ib., 1891); Ludwig, *Morphologische Studien an Echinodermen* (Leipzig, 1877-82); Neumayr, *Die Stamme des Thierreiches* (Vienna and Prague, 1889); W. B. Clark, "The Mesozoic Echinodermata of the United States," *Bulletin United States Geological Survey*, No. 97 (Washington, 1893). See also the works cited under the articles on various classes of echinoderms above referred to.

For description of the ontogeny or development of the echinoderms, consult the works by Lang and Bather mentioned in the bibliography. The following are intended to represent both the general history and the phylogenetic relationships of the various classes:

	Cambrian	Ordovician	Silurian	Devonian	Carboniferous	Permian	Triassic	Jurassic	Cretaceous	Tertiary	Quaternary

Clypeastridae											
Spatangoidae											
Echinoidea											
Echinodermata											

ECHINOIDEA, êk'i-noi'dê-â (Neo-Lat. nom. pl., from Gk. *êxivos*, *echinos*, hedgehog + *êidos*, *eidos*, form). One of the five classes of Echinodermata (q.v.), containing the sea urchins and their kindred. It is subdivided into four orders: (1) Palaeo-Echinoidea, all fossil; (2) Regularia, the typical globular echinoids, or sea urchins; (3) Clypeastridae, the flattened cake urchins and sand dollars; (4) Spatangoidae, the cordate heart urchins. For further details of existing forms, see SEA URCHIN. Consult Jackson, "Phylogeny of the Echini, with a Revision of the Palaeozoic Species," in *Memoirs of the Boston Society of Natural History*, vol. vi (1912).

ECHINOSPHERITES, ê-kî'nô-sfê-rî-têz (Neo-Lat., from Gk. *êxivos*, *echinos*, hedgehog + *σφαῖρα*, *sphaira*, ball). A genus of cystids with globose, nonpedunculate calyx, composed of numerous irregularly arranged plates, all of which are furnished with pore rhombs. Certain species, especially *Echinospherites aurantium*, occur in great abundance in the Ordovician of Russia and Scandinavia and also in that of North America. See CYSTOIDEA.

ECHIUM, êk'i-um. See VIPER'S BUGLOSS.

ECHIURIDA, êk'i-û-rî-dâ. An order of annelids. See ANNULATA.

ECHMIADZIN, êch'mê-âd-zên'. See ETCHMIADZIN.

ECHO (Lat., from Gk. *ἠχώ*, *Êchô*; cf. *ἡχώ*, *êchê*, sound, noise, echo). A personification in Greek mythology. According to the legend, the mountain nymph Echo, by her talking, detained Hera when she sought to surprise Zeus among

the mountain nymphs. As a punishment, the goddess deprived her of the power of speech unless first spoken to, when she was compelled to reply. The love of Pan for Echo was also celebrated by later poets. According to Ovid (*Met.* iii, 356-401) the nymph Echo, having conceived a hopeless passion for Narcissus, pined away until only her voice remained. A portico at Olympia, where there was a sevenfold echo, was called by the nymph's name. These stories of Echo date from the time of Euripides.

ECHO. Sound is produced by waves or vibrations of the air or through which it travels, and these waves on striking a surface are reflected according to the laws of reflection. A sound thus reflected is termed an echo, and the rule that the angle of incidence must equal the angle of reflection holds good, as in the case of light and other forms of wave motion. If the sound is reflected by an obstacle at right angles to the direction of propagation, the echo returns to an observer at the place where the sound originated. This phenomenon enables one to ascertain the distance to a cliff or other surface from which an echo is obtained, and is made use of by navigators when approaching in a fog a shore with cliffs. Knowing that sound at ordinary temperatures travels with an approximate velocity of 1125 feet per second, by multiplying this figure by the time between the sound—that of a steam whistle, e.g.—and the perception of the echo, we obtain the distance to the cliff and back. Reflection also takes place from the surface of a cloud, as is the case with thunder, and an uneven surface such as that presented from the edge of a wood, which often will furnish excellent echoes. Echoes in auditoriums often present unpleasant effects which are difficult to overcome, as they produce an interference of the sound waves that destroys the effect to the auditor. Proper consideration of the size and shape and of the nature of the reflecting surfaces must be given in designing an auditorium. Consult Sabine, *Architectural Acoustics* (Boston, 1900).

ECHO, IN MUSIC. 1. A subdued repetition of a phrase. 2. In large organs there is a separate set of pipes, placed at a distance so as to produce the effect of an echo. There are separate stops and generally also a special manual.

ECHO CAÑON. A long and deep gorge formed by the Weber River, in northern Utah, on the Union Pacific Railroad (Map: Utah, C 2). It is about 20 miles northeast of Salt Lake City, and is remarkable for its echoes and sublime scenery. The sides of the cañon are of bare rock and almost vertical. Owing to erosion, many of the rocks have assumed curious shapes.

ECHTER, êk'têr, MICHAEL (1812-79). A German mural painter. He was born in Munich, received his artistic training at the academy there, and assisted Julius Schnorr von Karolsfeld (q.v.) in the decoration of the *salle des fêtes* of the royal palace at Munich with 19 wall paintings derived from the history of Rudolph of Hapsburg, Charlemagne, and Frederick Barbarossa. With W. Kaulbach (q.v.) he restored certain mural works in the Berlin Museum, and subsequently he established himself in Munich, where he executed several important commissions, including decorative paintings in the Bavarian National Museum, and "The Battle on the Lechfeld," a large canvas to form one in a series of thirty historical pictures in the Maximilia-

neum. He also painted scenes from Wagnerian opera for King Louis II of Bavaria. In 1903 he was appointed a professor in the Munich School of Industrial Arts.

ECHTERMEYER, ɛk'tēr-mī'ēr, ERNST THEODOR (1805-44). A German critic and compiler, born at Liebenwerda. His *Auswahl deutscher Gedichte* (1837; 34th ed., 1903) has been widely circulated in Germany.

ECHTERNACH, ɛk'tēr-nāg. A town in the Grand Duchy of Luxemburg, situated amid beautiful scenery on the Sure, 18 miles northeast of Luxemburg. It is celebrated for its Benedictine abbey, founded in 698, which retained its autonomy until 1801. The Romanesque abbey church of St. Willibrord, dating from 1017, now restored, is noted for its archaeological features. The Dingstuhl, or Rathaus, and the Casino Garden are also noteworthy. Boat building is one of the chief industries; the manufacture of damask, wall paper, and faience is also carried on. "The Procession," peculiar to Echternach, in which from 12,000 to 15,000 persons from the surrounding region take part annually each Whit-Tuesday, dates from the eighteenth century, when the intercession of St. Willibrord was invoked against the cholera which was afflicting Germany and Holland. It has now come to be an annual occasion of pilgrimage, especially for those suffering with St. Vitus's dance. Pop., 1900, 3538; 1910, 4300. See Sax, *Beiträge zur geschichte der abtei Echternach* (Luxemburg, 1874).

ECHTER VON MESPELBRONN, fōn mēs-pēl-brōn. See JULIUS ECHTER VON MESPELBRONN.

ECHUCA (formerly HOPWOOD'S FERRY). A town and river port of Victoria, Australia, on a peninsula formed by the Murray and Campaspe rivers, 157 miles north of Melbourne (Map: Victoria, D 4). A roadway and railway bridge, 1905 feet long, of the Murray River Railway, connects Echuca with Moama, on the New South Wales side of the Murray River. It has important vineyards and wine factories and a considerable river trade in wool, wine, and red-gum timber. Pop., 1901, 4078; 1911, 3546.

ÉCIJA, ɛ'thē-há. A city in the Province of Seville, Spain, 47 miles east by north of the city of Seville, on the river Genil, at the head of navigation, and on the Córdoba-Cádiz Railway (Map: Spain, C 4). It is well built, the streets and plazas being clean and paved, and has handsome gardens. A fine promenade extends along the river, and in the Plaza Mayor stands the municipal building, one of the notable structures of the city. The Plaza de Toros, well known as the scene of some of the most exciting bullfights in Spain, occupies the site of the Roman amphitheatre. Ecija contains hospitals, asylums for orphans and the aged, barracks, and a large theatre. A long and narrow stone bridge spans the Genil at this point. The climate is excessively hot. The city is the centre of a productive agricultural section, and has important manufactures. Its footwear is known throughout Spain, and there are several woolen, linen, and silk mills, flour mills, and tanneries. Pop., 1900, 23,472; 1910, 23,217. Ecija is an ancient city, some ascribing its origin to the Greeks long before the rise of the Romans. Anciently known as *Istigi*, it was named *Colonia Julia Augusta Firma* by the Romans, under whom it ranked in importance with Córdoba and Seville. It occupied a prominent place as a border town in the struggle between the Moors

and Christians. There are still extant Roman remains, and several gates and towers representative of Moorish architecture.

ECK, ERNST WILHELM EBERHARD (1838-1901). A German jurist. He was born in Berlin and was educated at the university of that city and at Göttingen. He held professorships at Berlin (1872), Halle (1873-77), Breslau (1877-81), and Berlin (after 1881). His principal works include: *Die sogenannten doppelseitigen Klagen des römischen und gemeinen deutschen Rechts* (1870); *Die Verpflichtung des Verkäufers zur Gewährung des Eigentums nach römischem und gemeinem deutschen Recht* (1874); "Die Stellung des Erben," etc., in Bekker and Fischer, *Beiträge zur Beurteilung des Entwurfs eines bürgerlichen Gesetzbuchs* (1890).

ECK, HEINRICH (1837-). A German geologist. He was born at Gleiwitz, Silesia, and was educated at Breslau. After participating in the Prussian geological survey in Thuringia and Silesia, in 1862, he was appointed lecturer at the mining school in Berlin in 1866, and professor of mineralogy and geology at the Polytechnic Institute, Stuttgart, in 1871. His investigations are devoted principally to the Triassic deposits, and are discussed in numerous writings which appeared in the publications of the German Geological Society. His larger works include: *Über die Formationen des bunten Sandsteins und des Muschelkalks in Oberschlesien und ihre Versteinerungen* (1865); "Radersdorf und Umgegend," in *Abhandlungen zur geologischen Spezialkarte von Preussen*, vol. i (1872). He wrote also: *Das Erdbeben in der Gegend zwischen Strassburg, Forbach.....am 11. Juni 1887* (1892); *Verzeichnis der mineralogischen, geognostischen, geographischen und balneographischen Literatur von Baden, Württemberg, Hohenzollern...* (1880, with additions in 1901).

ECK, JOHANN MATER VON (1486-1543). A German theologian, the well-known adversary of Luther and a opponent of the Reformation. He was born at Eck (now Eick), Swabia, Nov. 13, 1486. He studied at Tübingen (1498), Tübingen (1499), and Freiburg (1501). He became doctor of theology at Freiburg in 1510, and professor of theology at Ingolstadt in the same year. In 1512 he became chancellor of the university and canon of Eichstätt, and held these positions the rest of his life. Luther sent him a copy of his thesis, and he wrote in reply the *Obelisci* (1518). Carlstadt (q.v.) and Luther wrote replies to this work, and in 1519 occurred the memorable disputation at Leipzig, lasting from June 27 to July 16. In 1520 he visited Rome and urged upon the Pope, Leo X, to take strong measures against Luther. The Pope consented, and Eck returned with a papal bull of condemnation in his pocket. From this time on he was prominent among the opponents of the Reformation in Germany and Switzerland. In 1525 he visited England, and was well received by Henry VIII. He disputed at Baden, Switzerland, in 1527, with Haller of Bern and Ecclampadius of Basel, and attended the Augsburg Diet in 1530. He also took part in the religious convocations held at Worms in 1540 and at Regensburg in 1543. He died at Ingolstadt, Feb. 10, 1543. His most important works are included in *Operum Johannis Eccii contra Lutherum* (Augsburg, 1530-35). He prepared a German translation of the Old Testament and

adopted Emser's translation of the New. Consult Wiedemann, *Dr. Johannes Eck* (Regensburg, 1865).

ECKARDT, ɛk'ärt, JULIUS VON (1836-1908). A Russo-German author and diplomat. He was born at Wolmar (Livonia), was educated at the universities of St. Petersburg, Dorpat, and Berlin, and with Bärens published the *Rigasche Zeitung*, a journal which served as the chief exponent of the principles of the German Constitutional party in the governments of Esthonia, Livonia, and Courland. In 1867 he became a resident of Germany, where he was associated with Gustav Freytag, the well-known novelist, at Leipzig, in the publication of the *Grenzboten* (a newspaper) from 1867 to 1870. In 1884 he was appointed a privy councillor of Prussia, and after 1885 he was German Consul successively at Tunis, Marseilles, Stockholm, Basel, and Zurich. His publications include *Jungrussisch und Altlivländisch* (2d ed., 1871) and *Die baltischen Provinzen Russlands* (2d ed., 1877). Many anonymous works on Russian affairs are also ascribed to him.

ECKARDT. See ECKHART.

ECKART. See ECKHARDT.

ECKEL'S, JAMES HERRON (1858-1907). An American banker and financial expert, born at Princeton, Ill. He graduated at the Albany Law School (New York) in 1880, and practiced law at Ottawa, Ill., from 1881 to 1893. From 1893 to 1897 he was United States Comptroller of the Currency, and in the presidential campaign of 1896 was a leading Gold-Standard Democrat. He became president of the Commercial National Bank of Chicago in 1898. He published *The Financial Power of the New West* (1905).

ECKER, ALEXANDER (1816-87). A German anatomist and anthropologist. He was born at Freiburg and was educated at the university in that city and at Heidelberg and Vienna. He was professor of anatomy and physiology at Basel from 1844 to 1850, when he was called in the same capacity to Freiburg, where he formed a valuable anthropological collection. The Museum of Etymology at Freiburg was also established by him. He was coeditor of the *Archiv für Anthropologie* and wrote the following publications: *Physiologische Untersuchungen über die Bewegungen des Gehirns und Rückenmarks* (1843); *Erläuterungstafeln zur Physiologie und Entwicklungsgeschichte* (1850-59); *Crania Germanica*, with 38 plates (1863-65); *Die Hirnwindungen des Menschen* (1869; 2d ed., 1882); *Die Anatomie des Frosches, ein Handbuch für Physiologen, Aerzte und Studierende* (3 parts, 1864-82; part i, 3d ed., parts ii and iii, 2d ed., 1896-1904); Eng. trans. by George Haslam, *The Anatomy of the Frog* (1889).

ECKERMANN, ɛk'ër-män, JOHANN PETER (1792-1854). A German author known for his intimate relations with Goethe, born at Winsen. He served in the War of Liberation (1813-14) and afterward studied at Hanover and Göttingen. In 1822 he sent Goethe the manuscript of his *Beiträge zur Poesie mit besonderer Hinreise auf Goethe*. Goethe was favorably impressed with the work, and in the following year Eckermann went to Weimar and became Goethe's private secretary. He held several minor public offices in the grand duchy after Goethe's death, but is memorable solely for his *Gespräche mit Goethe* (1836-48), a translation of parts i and ii, of which, by Margaret Fuller, appeared in

Boston in 1839, and a complete one by Oxenford in London (1850). There are translations in almost every European language, even Turkish. Eckermann published Goethe's *Nachgelassene Werke* (1832-33) and coöperated with Riemer in the edition of the *Samtliche Werke*, in 40 volumes (1839-40).

ECKERNFÖRDE, ɛk'ern-fär'de. A town and seaside resort in the Province of Schleswig-Holstein, Prussia, Germany, on the Baltic, 20 miles northwest of Kiel by rail (Map: German Empire, C 1). It stands on a strip of land dividing Eckernförde Bay into two portions, and has a fine harbor. It is the headquarters of the Prussian fisheries, and carries on a thriving trade in agricultural produce, salt, iron goods, lumber, hardware, and tobacco. Its public institutions include a teachers' college, a trade school, and a school of architecture. Pop., 1900, 6719; 1910, 6802.

ECKERSBERG, ɛk'ers-bèrk, JOHAN FREDERIK (1822-70). A Norwegian landscape painter. He was born at Drammen and studied at Düsseldorf under Schirmer, and afterward founded an important school at Christiania, Norway, in 1859. Among his works are "Sunrise in the High Mountains," a series of views of Madeira, where he lived some time for his health; "A View in Saeter Valley," in the Christiania Gallery, and a grand panoramic "Scene from a Norwegian Plateau," exhibited at the Paris Exposition of 1867.

ECKERSBERG, KRISTOFFER VILHELM (1783-1853). A Danish painter, born at Varnaes, Schleswig. He studied in Copenhagen under Abildgaard and in Paris under David, and from 1813 to 1816 lived in Rome, where he was strongly influenced by Thorvaldsen. On his return to Denmark he was made professor at the Academy of Copenhagen, and he founded the modern Danish school of painting. Although he lacks pictorial conception and imagination and uses dry and monotonous color, his sincere attitude towards nature and his good draftsmanship distinguish him above the artists of his day. He painted everything: biblical subjects, including "Moses Dividing the Waters of the Red Sea" (Copenhagen Museum); historical paintings, such as those in the throne room at Christiansborg; genre scenes, landscapes, marines and portraits, among which are the excellent and minutely executed likenesses of Anne Marie Magnani and Thorvaldsen.

ECKERT, ɛk'ért (FRIEDRICH EDUARD), MAX (1868-). A German cartographer and writer on commercial geography. He was born in Chemnitz, and was educated in Löbau and Berlin. He taught in Löbau and Leipzig; in 1903 became privatdozent in the University of Kiel, and in 1907 was appointed professor of geography in the Royal Technical High School of Aix-la-Chapelle. Among his publications are: an excellent *Schulatlas* (45th ed., 1912); *Wesen und Aufgabe der Wirtschafts- und Verkehrsgeographie* (1903); *Grundriss der Handelsgeographie* (1905); *Leitfaden der Handelsgeographie* (3d. ed., 1911); *Nepe Entwürfe für Erdkarten* (1906); *Die Kartographie als Wissenschaft* (1907); *The New Fields of Geography, especially Commercial Geography* (1907); *Geographisches Praktikum* (1908; with Krümmel); *Fortschritt in der geographischen Erschliessung unsern Kolonien* (1908 et seq.); *Die Kartenprojektion* (1910); *Deutsche Kulturgeographie* (1912); *Wirtschaftsatlas der deutschen Kolonien*

(1912); *Die wirtschaftliche Bedeutung des Panama-Kanals* (1913); *Die Metallverbreitung und Metallgewerbe der Welte* (1913).

ECKERT, THOMAS THOMPSON (1825-1910). An American telegrapher and manager of telegraph systems, born in St. Clairsville, Ohio. He superintended the military telegraph office at General McClellan's headquarters in 1861, and held a similar position with the Army of the Potomac during the Peninsular campaign. In 1862 he organized the military telegraph service in the War Department buildings at Washington. At the close of the war he received the brevet rank of brigadier general, and from 1864 to 1866 was Assistant Secretary of War. He was superintendent of the eastern division of the Western Union Telegraph Company from 1866 to 1875, and was president of the Atlantic and Pacific Telegraph Company from 1875 to 1880, and of the American Union Telegraph Company from 1880 to 1881. On the consolidation of these two corporations with the Western Union, in 1881, he was elected vice president and general manager of the latter, in 1892 became president and manager, and retired early in 1902.

ECKFORD, HENRY (1775-1832). An American naval architect. He was born in Irvine, Scotland, and when 16 years old became a shipwright in the shipyards of his uncle, John Black, at Quebec. In 1796 he removed to New York and established a shipyard of his own. During the War of 1812 he constructed a fleet of ships of war upon Lake Erie in a remarkably short period of time. He was the builder of the *Robert Fulton*, which made the first successful ocean trip ever made by a steamship, from New York to New Orleans and Havana. In 1820 he was appointed naval constructor in charge of the Brooklyn Navy Yard, where he designed and superintended the construction of six ships of war. Leaving the service of the Government, he engaged again in shipbuilding on his own account, and constructed vessels for several European and South American countries. In 1831 he built a frigate at Philadelphia for the Sultan of Turkey, and accompanied it to Constantinople, where the Sultan offered him the position of chief constructor in his navy. He established a navy yard there, and, while engaged on plans for some new ships, died at Constantinople in the following year.

ECKHARDT,   k'h  rt, or ECKART, THE TRUSTY (Ger. *der getreue Eckart*). In German legend, an old man whose doom it is to precede the spectral band of Frau Holle ("Die wilde Jagd"), in their wild ride through the country, and to warn all whom he meets, but especially children, of their approaching danger. According to another version Eckhardt sits at the entrance to the Venusberg, to dissuade those who would enter, and often attends the goddess on her journeys.

ECKHART, or ECKARDT, JOHANNES (c. 1260-1327). A noted German mystic, generally called Meister (Master) Eckhart. He was of the Dominican Order, and in 1298 became prior at Erfurt and vicar of Thuringia. In 1303 he was made provincial of his Order for Saxony, and in 1307 vicar-general of Bohemia. For several years he lectured at Paris. He was distinguished for practical reforms and for his power as a preacher. His writings show the results of contact with the Beghards (see BEGUINES) and Brethren of the Free Spirit. The

opponents of the Beghards found some propositions in Eckhart's works for which he was called to account by the Inquisition at Cologne in 1327. He made a recantation and appealed to the Pope, by whom some of his propositions were formally condemned. Probably before the issuing of this condemnation Eckhart died. His works show that he was deeply learned in all the philosophy of the time, and a profound thinker. His style is without system, brief, mystical, and full of symbolical expressions; but his thinking was clear, calm, and logical, and he gave the most complete exposition of what may be called Christian pantheism. The starting point of his doctrine is that, apart from God, there is no real being. But, in his view, God is the unknown. Anything definitely ascribed to the Godhead would limit and therefore destroy its infinity. The Godhead is not God as known to us. From it proceeds the triune God, who is known. The essence of the Godhead is what it is in itself; its nature is that which it becomes as an object for others. It reveals itself in the personal God, the Father. The Son is the word or expression through and in which the Father becomes self-conscious. The Father eternally begets the Son, and the Son's return into the Father in love and mutual will is the Spirit. The Father is not before the Son; only through the begetting of the Son, only through arriving at self-consciousness, does He become the Father. The genesis of the Son from the Father involves also the production of the world of things; for God is reason, and in reason is contained the ideal world of creatures. In the Son all things are made in ideal form. As all things have arisen from God, so they all tend to return to Him. Repose in Him is the end of all things; and in man, the noblest of creatures, this end may be realized. Man has the power of reaching to the Absolute. This power—which Eckhart called *the spark*—is in truth God working in man. In knowing God, God and man are one; there is no distinction of knower and known. Union with God—the birth of the Son in the soul—is the ultimate end of activity, and is to be attained by resigning all individuality. When this union is reached the soul is one with God; its will is God's; it cannot sin. Yet all this applies only to the "spark" in the soul, the other powers of which may be properly employed about other things. Thus, the way is left open to adjust the balance between feeling and action, between philosophical theory and practical life. Consult: Pfeiffer, "Meister Eckart," second volume of *Deutsche Mystiker* (Leipzig, 1857), containing a rich selection from his writings; *Meister Eckhart* (Hamburg, 1842); Preger, *Geschichte der deutschen Mystik im Mittelalter* (Leipzig, 1874); *Meister Eckhart's mystische Schriften* (Berlin, 1903); *Schriften und Predigen* (Jena, 1909); Hartmann, *Die Geheimlehre in der christliche Religion nach den Erkl  rungen von Meister Eckhart* (Leipzig, 1895); Vaughan, *Hours with the Mystics* (London, 1860).

ECKHART, JOHANN GEORG VON (1664-1730). A German historian, born at Duingen. He studied at Leipzig, in 1694 became an assistant to Leibniz in the latter's historical studies, and in 1700 professor of history at Helmstedt. Elevated to the nobility, he was in 1724 appointed librarian at the court of the prince-bishop of W  rzburg. Among his works are the *Corpus Historicum Medii   vi* (1723) and the

Commentarii de Rebus Franciæ Orientalis et Episcopatus Wirceburgensis (1729), long-standing authorities on the times of which they treat.

ECKHEL, êk'el, JOSEPH HILARIUS (1737-98). An eminent Austrian numismatist, born at Enzersfeld. He was educated at the Jesuits' College in Vienna, and in 1751 entered the society. His knowledge of numismatics soon won him the place of keeper of coins and medals in the Jesuits' College at Vienna. In 1772 he went to Italy, where for two years he was engaged in the study of coins; on his return to Vienna he was made director of the Imperial Cabinet of Medals and professor of archaeology at the university. Beginning with 1775, he published numerous works on coins and gems, but his greatest work is his *Doctrina Numorum Veterum* (3 vols., 1792-98). A supplementary volume was added in 1826 from papers left by Eckhel at his death; this volume also contains an account of his life and writings. By his great work Eckhel became the founder of scientific numismatics. Consult Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908). See NUMISMATICS, *History of Numismatic Studies*.

ECKHOF, êk'hôf, KONRAD. See EKHOF.

ECKMÜHL, êk'mûl, or **EGGMÜHL**. A village of Bavaria, on the Grosse Laber, 13 miles south-southeast of Ratisbon, noted for the battle fought there on April 22, 1809, between 75,000 French and 40,000 Austrians. The Austrian Archduke Charles had taken up his position on the right bank of the Danube, near Ratisbon. From this point, at the head of four divisions of the Austrian army, he threatened the French position at Donaauwörth. Davout, however, succeeded in keeping him in check, while Napoleon, swinging round to the southeast, interposed himself between the road to Vienna and the Austrian army, with which he came face to face at Eckmühl. The action on the side of the French was commenced by Lannes, who drove back the Austrian left, while at the same time the village of Eckmühl was stormed by the Württembergers. Shortly afterward the high grounds between Eckmühl and Laichling, also occupied by the Austrians, were abandoned after an heroic struggle, and the Archduke ordered a retreat on Ratisbon, which was admirably executed, though at the sacrifice of the entire Austrian cavalry, who were cut to pieces at Eylofstein while covering the movement. The Austrians lost nearly 30,000 men at Eckmühl and in the two days' fighting that preceded it. The French loss was much less.

ECKMÜHL, PRINCE OF. See DAVOUT.

ECKSTEIN, êk'stîn, ERNST (1845-1901). A versatile German humorist, poet, and novelist, born at Giessen. His first literary work, *Schach der Königin* (1870) and *Pariser Silhouetten* (1873), was done in France, as were the grotesque *Die Gespenster von Varzin* (1870) and *Der Stumme von Sevilla* (1871). His travels in Italy and Spain resulted in the stories *Margherita*, *Am Grabmal des Cestius*, and *Die Moschee von Cordova*. He returned to Germany, lived for several years in Leipzig as editor of a literary journal and of a comic weekly, and wrote many brilliantly humorous sketches, of which the side-splitting *Besuch in Carcer* is typical. In 1885 he moved to Dresden, and afterward wrote several serious novels of classical life, among which *Die Claudier* (1882), *Prusias* (1883), *Aphrodite* (1886), *Pia* (1887), and *Nero* (1889) are noteworthy. *Familie*

Hartwig (1894) is his best novel. His lyrics are carefully polished, and some of his translations are models.

ECLECTICISM (from *eclectic*, from Gk. ἐκλεκτικός, *eklektikos*, selecting, from ἐκλέγειν, *eklegein*, to select, from ἐκ, *ek*, out + λέγειν, *legein*, to gather). In philosophy, an attempt to piece together from various competing systems such elements as may, to superficial view, appear fairly compatible. The prevailing motive is usually practical, being a desire to get a set of opinions which shall lend their support to moral and religious life. Eclecticism appears wherever great speculative power is wanting at the same time that the conflict between traditional schools is vigorously carried on without much appreciation of the reach of the principles involved. Under such conditions many thinkers prefer to keep out of the strife of the schools, and endeavor to satisfy their not very exacting intellectual demands by selecting here and there what appears to go together to form a satisfactory intellectual foundation for the needs of this life. In ancient philosophy, Cicero was the most conspicuous if not the greatest representative of this tendency, adopting elements from the Skeptic, the Stoic, and the Peripatetic schools without any systematic outcome from this. From his day to this, eclectics have been numerous. Cousin (q.v.) is often called the great modern eclectic, but perhaps this characterization fails to do justice to his desire to get a consistent system rather than a merely edifying one. Every great philosopher gathers his materials wherever he finds them. He is not troubled by the fact that he finds them in mutually hostile territories. But what distinguishes him from the eclectic is his desire to know what is true rather than to believe what is helpful, and above all his ability to weave his materials together into a consistent fabric.

ECLECTIC SCHOOL OF MEDICINE, AMERICAN, or NEW SCHOOL OF MEDICINE. The modern representative of a school of medical thought which existed as early as 200 B.C. Its adherents contended that the wisdom of the various schools was a vain thing, and that the individual could choose for himself between the good and the bad. They, therefore, rejected all knowledge gained by the experience of others. The modern revival took place in America in the early part of the nineteenth century. The modern eclectic professes still to take what is best in medicine, and is still an individualist. In 1826 an eclectic college was founded in New York by Wooster Beach, who was the author of several textbooks for the school. Soon afterward schools were established in Ohio and other States, and at a later period regular colleges in New York, Chicago, and other cities. State societies were formed, and in 1870 the National Eclectic Medical Association was incorporated by the New York Legislature. In 1914 the United States contained 4 eclectic colleges, with 270 students. The prominent feature of the school is the theoretical rejection of mercury and most other mineral substances in medicine. Another distinctive point in modern eclectic practice is the use of native medicinal plants, and from the studies of some American eclectic teachers much useful information has been gained respecting these plants. Consult Beach, *The American Practice of Medicine* (New York, 1838), and Wilder, *History of Medicine* (New Sharon, Me., 1901).

ECLECTIC SCHOOL OF PAINTING. See BOLOGNESE SCHOOL OF PAINTING.

ECLIPSE (Lat. *eclipsis*, from Gk. *ἐκλείψις*, *ekleipsis*, eclipse, from *ἐκλείπειν*, *ekleipein*, to forsake, fail, from *ἐκ*, *ek*, out + *λείπειν*, *leipein*, to leave). Sometimes one or other of the self-luminous heavenly bodies is shut off from our view temporarily by the interposition of some other body between it and the earth. This is called an eclipse when the object temporarily obscured is the sun, and an occultation (q.v.) when it is a star. Nonluminous bodies, which shine only by reflected solar light, may be "eclipsed" by having the light cut off by a body passing between themselves and the sun; and they may be "occulted" by being concealed behind a body passing between themselves and the earth. The term "transit" is applied to the partial concealment of the sun by the passage across his face of Venus or Mercury, and to the similar phenomena of the passages of Jupiter's satellites across his disk. The causes of eclipse as here suggested are so simple and familiar that it is difficult for us to imagine how deeply eclipses affected men's minds before the dawn of astronomical science. At Rome, at one time, it was blasphemy, and punished by law, to talk publicly of their being due to natural causes. According to some, Luna, when in eclipse, was in the pains of labor; according to others, she was suffering from the arts of wicked magicians. The Chinese imagine eclipses to be caused by great dragons . . . to devour the sun and moon, and . . . they beat drums and brass kettles to terrify the monsters into letting go their prey. Chinese annals of the 22d century B.C. record that, on the occasion of a solar eclipse which took place in the reign of the Emperor Chung K'ang, the state astronomers, Hsi and Ho, were drunk and incapable of attending to their duties as supervisors of the prescribed rites, and were, in consequence, put to death. Solar eclipses can occur only at the time of new moon, when the sun and moon are in conjunction on the same side of the earth. In a partial eclipse, the sun's disk suddenly loses its circular form; it becomes indented on one side, the indentation slowly increasing for some time, and then diminishing until it disappears altogether. In a total eclipse, the indentation goes on increasing till the whole orb disappears for a time; after a short interval, the sun reappears again, passing through the same stages of obscuration in an inverse order. . . . In a partial eclipse, the whole sun is obscured except a ring or annulus. Lunar eclipses, on the other hand, always occur at full moon, or when the sun and moon are in opposition, and are caused by the moon passing through the earth's shadow. Such eclipses are sometimes partial and sometimes total, but never annular, and in their general phases they resemble those of the sun. The duration of an eclipse is the time of its continuance, or the interval between immersion and emersion. Immersion, or incidence, of an eclipse is the moment when part of the luminary begins to be obscured; emersion is the time when the luminary begins to reappear or emerge from the shadow. When the size of an eclipse is mentioned, the part of the luminary obscured is obtained by dividing its diameter into 12 digits; and the eclipse is said to be of so many digits, according to the number of them contained in that part of the diameter which is obscured.

Eclipses of the Moon. It has been said that

these are caused by the moon passing through the earth's shadow. Before this explanation can be accepted, it must be shown that that shadow extends as far as the moon. This is easily done. Supposing the earth to have no atmosphere, then the shadow is the cone marked in shade in Fig. 1, in which *T* and *S* are the centres of the earth

FIG. 1.

and sun. The cone's apex is at *O*; and the question is, whether the distance *OT* from the apex to the earth's centre exceeds the moon's distance from the earth. Drawing *TB*, *SA*, from the centres of the earth and sun, respectively, perpendicular to the line *OBA*, tangent to both spheres, and the line *TC* parallel to the line *OBA*, we have from the similar triangles *OTB*, *TSC*, the proportion, *OT* : *TB* : : *TS* : *SC*. Now, we know that *TS*, the (mean) distance of the sun, is equal to about 24,000 times *TB*; also, from the construction, *AC* = *TB*; and we know that *SA* = 112 times *TB*; whence it follows that *SC* = 111 times *TB*. The above proportion then gives *OT* = 216 times *TB*, since $\frac{24,000}{111} = 216$ nearly. But the moon's average distance is only 60 times *TB* (the earth's radius). Hence it appears that the length of the earth's shadow is almost four times the average distance of the moon, and that the moon can enter it. Further, it is clear that, should it do so, it may be totally obscured; for it must enter at a point much nearer *T* than half the distance *OT*, which is 108 times *TB*; and everywhere within that distance, it might be shown, the breadth of the shadow is much greater than the moon's disk. But one consideration now remains to be stated to complete the proof of the theory of lunar eclipses. It was mentioned that they only occur at full moon, and we know that to be the only time when the earth is between the sun and moon, and so has a chance of throwing her shadow upon it. Why they do not occur every full moon will be explained in treating of the prediction of eclipses.

In the foregoing explanation, we proceeded on the assumption that the earth has no atmosphere. If this assumption were correct, the earth's shadow would be darker and narrower than it is, and the phenomena of eclipses more sudden. The effect of atmospheric refraction (see REFRACTION) is to bend the rays which fall on the atmosphere in towards the axis of the cone of the earth's shadow, those which pass through the lowest strata of the air being refracted through an angle of $1^{\circ} 8'$, and converging to a point in the line *OT* (Fig. 1) considerably nearer the earth than the point where the moon crosses her shadow. As a result of this, the moon never enters that part of the shadow which is completely dark; thus, she never loses her light entirely, but appears of a distinct reddish color resembling tarnished metal. This appearance is caused by the atmospheric refraction in the same way as the ruddy color of the clouds at sunset. There is another reason why the phenomena of a lunar eclipse are less striking than might be expected from the explanation given relative to Fig. 1. Every shadow cast by the sun's rays

necessarily has a penumbra, or envelope, on both sides of the central cone. In the case before us (Fig. 2), suppose a cone having its apex

FIG. 2.

O' between the sun and the earth, and enveloping each of them respectively in its opposite halves $CO'C'$ and $AO'A'$. It is clear that from every point in the shaded part of the cone $CO'C'$ but without the shadow BOB' , a portion of the sun will be visible—and a portion only—the portion increasing as the point approaches either of the lines $CB, C'B'$, and diminishing as it approaches the lines $BO, B'O$. In other words, the illumination from the sun's rays is only partial within the space referred to, and diminishes from its extreme boundary line towards the lines $BO, B'O$. When, then, the moon is about to suffer eclipse, it first loses brightness on entering this penumbra; so that when it enters the real shadow, the contrast is not between one part of it in shade and the other in full brilliancy, but between a part in shade and a part in partial shade. On its emersion, the same contrast is presented between the part in the umbra and the part in the penumbra. What we should expect on this geometric view of the earth's shadow, actually happens. From the breadth of the penumbra, it happens that the moon may fall wholly within it before immersion in the umbra commences; and so softly do the degrees of light shade into one another, that it is difficult to tell when a remarkable point on the moon's surface leaves the penumbra to pass into the umbra, or the reverse.

Prediction of Lunar Eclipses. We said that lunar eclipses happen only at full moon. They do not happen every full moon, because the moon's orbit is inclined to the ecliptic, on which the centre of the earth's shadow moves at an angle of $5^\circ 9'$ nearly. Of course, if the moon moved on the ecliptic, there would be an eclipse every full moon; but from the magnitude of the angle of inclination of her orbit to the ecliptic, an eclipse can only occur on a full moon happening when the moon is at or near one of her nodes, or the points where her orbit intersects the ecliptic. An eclipse clearly can happen only when the centres of the circle of the earth's shadow and of the moon's disk approach within a distance less than the sum of their apparent semidiameters. This sum is very small; so that except when near the nodes, the moon, on whichever side of the ecliptic she may be, may pass above or below the shadow without entering it in the least. The moon's average diameter is known to be $31' 8.2''$, and from the *American Ephemeris*, or the *British Nautical Almanac*, we may ascertain its exact amount for any hour—its variations all taking place between the values $29' 24''$ and $33' 32''$. As for the diameter of the circle of the shadow, as seen from the earth's centre, it is easily found by geometric construction and calculation and is shown to vary between $1^\circ 16' 36''$ and $1^\circ 30' 38''$; and its value for any time may be found from the *American Ephemeris*, or the *British Nautical Almanac*, to which value astronomers usually add about

$1' 30''$, as a correction for their calculation, which proceeds on the assumption that the earth has no atmosphere. Starting from these elements, it is a simple problem in spherical trigonometry (which may be solved approximately by plane trigonometry by supposing the moon and the earth's shadow to move for a short time near the node in straight lines) to fix the limits within which the shadow and moon must concur to allow of an eclipse. Recollecting that the earth's shadow on the ecliptic is at the opposite end of the diameter from the sun, and that therefore as it nears one node the sun must approach the other—the sun and shadow being always equidistant from the opposite nodes—we find, from the solution of the above problem: (1) that if, at the time of full moon, the distance of the sun's centre from the nearest node be greater than $12^\circ 15'$, there cannot be an eclipse; (2) if at that time the distance of the sun's centre from the nearest node be less than $9^\circ 30'$, there will certainly be an eclipse; (3) if the distance of the sun's centre from a node be between these values, it is doubtful whether there will be an eclipse, and a detailed calculation must be resorted to, to ascertain whether there will be one or not. It may here be mentioned that before the laws of the solar and lunar motions were discovered with anything like accuracy, the ancients were able to predict the dates of lunar eclipses with tolerable correctness by means of the eclipse cycle or Saros (see PERIOD) of 18 Julian years and 11 days. Their power of doing so turned on this, that in 223 lunations the moon returns almost to the same position in the heavens. If she did return to exactly the same position, then, by simply observing the eclipses which occurred during the 223 lunations, we should know the order in which they would recur in all time coming.

All lunar eclipses are visible in all parts of the earth which have the moon above their horizon, and are everywhere of the same magnitude, with the same beginning and end; and this universality of lunar eclipses is the reason why it is popularly thought, contrary to fact, that they are of more frequent occurrence than solar eclipses. The eastern side of the moon, or left-hand side as we look towards her from the north, is that which first immerges and emerges again. The reason of this is that the motion of the moon is swifter than that of the earth's shadow, so that she overtakes it with her east side foremost, passes through it, and leaves it behind to the west. It will be readily understood from the explanations above given that total eclipses of the longest duration happen in the very nodes of the ecliptic. But from the circumstance of the circle of the shadow being much greater than the moon's disk, total eclipses may happen within a small distance of the nodes, in which cases, however, their duration is less. The farther the moon is from her node at the time, the smaller is the eclipse, till, in the limiting case, she just touches the shadow, and passes on unobscured.

Eclipses of the Sun. These are caused, as we have stated, by the interposition of the moon between the earth and sun, through which a greater or less portion of the sun is necessarily hid from view. By a process similar to that used in ascertaining the length of the earth's shadow, it can be shown that the greatest value of the length of the moon's shadow is about 60

semidiameters of the earth; at the same time, we know that the least distance of the moon from the earth is about 56 semidiameters. It follows that when a conjunction of the sun and moon happens at a time when the length of the shadow and the distance of the moon from the earth are, or are nearly, equal to the value above stated, the moon's shadow extends to the earth and beyond it. Should the shadow in these circumstances fall upon the earth, there will be a total eclipse of the sun in all places

FIG. 3.

within it or over which it moves. If L (Fig. 3) be the moon, T the earth, and abL the moon's shadow cast by the sun, there will be a total eclipse of the sun at every point that is completely within the portion ab of the earth's surface. Again, the smallest value of the length of the moon's shadow may be shown to be about 58 semidiameters of the earth, and the greatest distance of the moon from the earth is about 64 semidiameters. Suppose the moon interposed between the earth and sun when these values concur, it is clear that the moon's shadow will fall short of the earth. In this case, the sun cannot be altogether hid from any point of the earth's surface; but this case, or one approximate to it, is that in which there will occur an annular eclipse. In Fig. 4, suppose O to be the

FIG. 4.

apex of the shadow which falls short of the earth, and conceive the cone of the shadow produced earthward beyond O into a second cone Ocd ; then from every point within the section cd of the earth's surface the moon will be seen projected as a black disk on the middle of the disk of the sun, the portion unobscured forming a ring or annulus of light. While in the two cases just described the eclipse is total or regular at places within ab (Fig. 3) or cd (Fig. 4), respectively, it will be partial at other places; the moon will appear projected against a portion of the sun's disk, making a circular indentation. To ascertain the places at which the eclipse will be partial, we have merely to form the cone of the penumbra of the moon's shadow in the manner explained in treating of lunar eclipses; at all places on the earth's surface within that cone there will be a partial eclipse. A simple calculation shows what is the observed fact, that the cone of the penumbra is not nearly large enough to embrace the whole of the face of the earth directed to the sun; in other words, solar eclipses are not universal, like those of the moon, i.e., they are not seen from all places that have the sun above their horizon at the time of the eclipse, which is the reason that though they are of more frequent occurrence than lunar eclipses, the latter are more frequently seen by the public, and there-

fore commonly supposed to occur more frequently. There are certain appearances, attending an eclipse of the sun, when it is total, that are very remarkable. The darkening of the orb of day, more particularly when it is unlooked for, is calculated to impress a spectator with vague terror; even when expected, it fills the mind with awe. The sudden darkness, too, is impressive from its strangeness; it resembles neither the darkness of night nor the gloom of twilight. Stars and planets appear, and all animals are dismayed by the gloomy aspect of nature.

There is one important phenomenon attending total eclipses of the sun, which is always seen and the cause of which cannot be said to be as yet fully understood. As long as the total eclipse lasts there appears round the sun and moon a luminous corona, while at its base, and projecting beyond the dark edge of the moon, appear very brilliant prominences, generally of a red color. These prominences are found to be constant attendants on eclipses, and methods have been invented for rendering them visible at any time without the interposition of the moon. The spectroscope shows that they consist mainly of hydrogen gas in an incandescent state. The prominences are sometimes seen to shoot up like flames, in wild fantastic shapes, with incredible velocity, and to the height of hundreds of thousands of miles.

The first eclipse photographs of the sun were obtained at the eclipse of 1851, but it was not until that of 1860 that photography was systematically employed in the observation of solar eclipses. On that occasion De La Rue and Father Secchi, at different stations in Spain, secured photographs which definitely established the chromosphere as a solar appendage. The Indian eclipse of 1868 saw the spectroscope added to the instrumental resources of the eclipse observer, and the gaseous nature of the chromosphere and its prominences was revealed when the bright lines due to hydrogen were observed; another important discovery was that of the orange line of helium which, however, was attributed at the time to the presence of sodium in the chromosphere. In the North American eclipse of 1869 the corona yielded a continuous spectrum traversed by a single green line, which was at first identified with one of the iron lines, but is now recognized as due to an element unknown to terrestrial chemistry, to which the name "coronium" has been given. The Spanish eclipse of 1870 was marked by Young's discovery of the "reversing layer." In recent years no total eclipse, if at all accessible, has been allowed to pass without the dispatch of several expeditions, usually manned by astronomers from the leading observatories, but occasionally due to private initiative, and, except in a few cases where adverse weather conditions have led to failure, each has added confirmation of previous discoveries, or has raised new questions the solution of which has been left to succeeding expeditions. See CHROMOSPHERE; SUN.

Prediction of Solar Eclipses. The period of 18 Julian years 11 days, referred to in treating of the prediction of lunar eclipses, applies equally to solar eclipses; but the ancients, who understood that fact, could find no law of recurrence of solar eclipses within that period so as to predict them. The reason of the failure is obvious; for though solar eclipses recur in a

fixed order within the cycle, they are not visible at the same places on their recurrence as when first observed. By modern methods, however, eclipses of the sun may be predicted, with all their circumstances of time and places of observation, with the most perfect certainty. At the time of a solar eclipse the sun and moon are in conjunction; they are also in or near the same node; and no eclipse can happen if they are farther than $18^{\circ} 31'$ from the node, or if the latitude of the moon, viewed from the earth, exceeds the sum of the apparent semi-diameters of the sun and moon. When within these limits, it is a problem of numbers and of spherical trigonometry to ascertain whether an eclipse will actually occur and what its circumstances will be.

The number of eclipses of the sun and moon together in a year cannot be less than two—in which case both are solar—or more than seven, five solar and two lunar, or four solar and three lunar; but total solar eclipses are extremely infrequent in any one place, compared with the actual frequency of their occurrence. Thus, total eclipses were visible somewhere in the United States during the nineteenth century only in the years 1806, 1834, 1860, 1869, 1878, 1880, 1889, 1900; and in the present century such eclipses will be visible in the years 1918, 1923, 1925, 1945, 1954, 1979, 1984, and 1994. For a very complete list of eclipse dates, consult Newcomb, "On the Recurrence of Solar Eclipses, with Tables of Eclipses from 700 B.C. to 2300 A.D.," in *Astronomical Papers* (Washington, 1882), and Oppolzer, *Kanon der Finsternisse* (Vienna, 1887).

Notable Eclipses of Antiquity. Besides the solar eclipse already referred to as having been the occasion of the death of the Chinese astronomers, Hsi and Ho, many other notable eclipses, both of the sun and the moon, are recorded in history. Several are mentioned in Babylonian and Assyrian annals, one of the best authenticated being a total eclipse of the sun which took place at Nineveh on June 15, 763 B.C. On May 28, 585 B.C., occurred the famous eclipse predicted by Thales, of Miletus, which is said to have put a stop to the battle of the Halys between the Medes and Lydians. Thucydides mentions an annular eclipse of the sun which took place on Aug. 3, 481 B.C., during the first year of the Peloponnesian War; and another is recorded in 394 B.C. as occurring a few days after the sea fight off Cnidus in which Conon defeated the Persians. The Carthaginian expedition of Agathocles, the Tyrant of Syracuse, landed in Africa during a total eclipse of the sun in 310 B.C. During the Third Macedonian War Sulpicius Gallus, one of the Roman officers, foretold a total eclipse of the moon which occurred on the eve of the battle of Pydna in which the Romans in 168 B.C. defeated Perseus, the Macedonian King; it is said that he announced the coming eclipse to the assembled army, that it might not be regarded as a bad omen. Several eclipses find mention in the *Anglo-Saxon Chronicle* and are associated by the chronicler with notable contemporaneous events. A complete list of eclipses from 900 B.C. to 600 A.D., with identifications with recorded eclipses, may be found in Ginzel, *Spezieller Kanon der Sonnen- und Mondfinsternisse* (Berlin, 1899). Consult Lockyer, *Recent and Coming Eclipses* (New York, 1900); Buchanan, *Mathematical Theory of Eclipses* (Phil-

adelphia, 1904); Lynn, *Remarkable Eclipses* (London, 1906).

ECLIPTIC (Lat. *eclipticus*, from Gk. *ἐκλειπτικός*, *ekleiptikos*, relating to an eclipse, from *ἐκλείψω*, *ekleipsis*, eclipse). The great circle of the heavens round which the sun seems to travel from west to east in the course of a year. It took its name from the early observed fact that eclipses (see ECLIPSE) happen only when the sun and moon are in or near this circle. Attention about sunset or sunrise shows that the sun is constantly altering his position among the stars visible near him, leaving them every day a little farther to the west. That this motion is not exactly east and west, or parallel to the celestial equator, becomes evident by observing that the sun's height at midday is constantly altering. It was discovered very early in the history of astronomy that twice a year, about March 21 and September 23, the sun is exactly on the equator. The two points of the equator on which the sun then stands are the equinoctial points (see EQUINOXES; EQUINOCTIAL) and are the intersections of the equator and ecliptic. Again, there are two days in the year on which the sun reaches his greatest and his least midday elevation in the Northern Hemisphere—the first is the 21st of June; the second, the 21st of December. On these days the sun has reached his greatest distance from the equator either way, and the points in his course where he thus seems to pause or halt in his retreat from the equator are called the solstices (*solis stationes*). The solstices are halfway between the equinoxes, so that these four points divide the ecliptic into four quadrants, each of which is divided into three arcs of 30° . The 12 arcs into which the ecliptic is thus divided are called signs of the zodiac (q.v.). These arcs or signs have been named after constellations through which the ecliptic passes. As the equinoctial points are not fixed, but recede yearly westward about $50''$, and in the century about $1^{\circ} 24'$, the same constellations and signs that coincided when the division of the ecliptic took place no longer coincide. The constellation of the Ram, e.g., which originally stood in the first arc or sign, now stands in the second, every constellation having advanced forward 30° , or a whole sign. Modern astronomers therefore pay little attention to these constellations and signs, but measure celestial longitudes from the existing spring equinoctial point, reckoning them from 0° to 360° . Not only do the points change where the ecliptic and equator cross each other, but the angle between these two circles, called the obliquity of the ecliptic, is also variable. It is at present nearly 23.5° and is diminishing at the rate of about $50''$ in a century. Were it to go on diminishing always, the ecliptic and the equator would at last coincide. The decrease, however, has a limit; the obliquity oscillates between two definite bounds, which it can never pass. It has been calculated that the diminution will continue for about 150 centuries, when the obliquity will amount to only 22.25° . After that it will again increase, tending towards an upper limit of about 25° . These slight alterations cannot sensibly affect the seasons.

The physical cause of this change of the obliquity is the gravitational action of the other planets, especially Jupiter, Mars, and Venus, on the mass of the earth. The fact of the change was known to astronomers in very

ancient times; Herodotus mentions an old tradition of the Egyptians that the ecliptic had formerly been perpendicular to the equator—a notion into which they were most probably led by observing for a long series of years that its obliquity was constantly diminishing. Though it was not until after the discovery of the law of gravitation that the change of the obliquity could be explained, yet that it was changing was long believed by many astronomers, although some doubted whether the differences in the values at different times were not due to errors of observation. The earliest-known measure of the obliquity of the ecliptic was probably made in China.

ECLOGITE (from Gk. *ἐκλογος*, *eklogos*, selected, from *ἐκλέγειν*, *eklegein*, to select, from *ἐκ*, *ek*, out + *λέγειν*, *legein*, to gather). A variety of metamorphic crystalline rock, remarkable for its composition and great beauty. It has a ground mass of pale-green pyroxene and hornblende, in which reddish crystals of garnet and blue crystals of cyanite are included. The rock is of rare occurrence, being found only in a few regions where Archæan gneisses and schists are exposed. The type locality for eclogite is the Bavarian Fichtelgebirge.

ECLOGUE (Lat. *ecloga*, Gk. *ἐκλογή*, *eklogê*, selection, from *ἐκλέγειν*, *eklegein*, to select). A pastoral poem, in which are related the loves and adventures of shepherds and shepherdesses in some ideal scene and period. This kind of poetry flourished among the ancients, Theocritus and Vergil being well-known examples. Under the name of pastorals, eclogues were fashionable in the sixteenth century. A good English specimen is Spenser's *Shepherd's Calendar*. They were revived in the eighteenth century by Ambrose Philips and Pope, but are no longer written. The term, however, is still applied to poems descriptive of country life and scenes. For the recent treatment of the eclogue, consult Bridges, "New Poems," in *Poetical Works* (London, 1899). See PASTORAL POETRY.

EC'NOMUS. A hill near Licata, on the southern coast of Sicily, which gave its name to the famous naval battle in which Regulus in 256 B.C. vanquished the Carthaginians.

ÉCOLE DES BEAUX-ARTS, á'kôl' dâ bô'-zâr' (properly ÉCOLE NATIONALE ET SPÉCIALE DES BEAUX-ARTS). The national school of the fine arts in France, probably the most important institution of the kind in the world. It was founded in 1648, coincidently with the Académie Royal de Peinture et de Sculpture, as the academic school where each professor in turn gave instruction in drawing. It did not receive its official title until 1793. Since then the only changes have been in the form of its administration. In 1815 the Académie des Beaux-Arts was given its present name, and in 1863 the outside ateliers, which are practically workshops, were added to the main Ecole. The Academy judges the yearly competition for the Prix de Rome (q.v.), directs the Academy at Rome, and has charge of the Ecole generally. The Academy of Architecture was annexed to the Academy of Painting and Sculpture in 1671, with François Blondel as its first professor, and was incorporated into the Académie des Beaux-Arts in 1793. The School of Architecture is now one of the most important branches of the Ecole des Beaux-Arts. In 1666 the Prix de Rome was instituted, and in the same year the Académie de France at Rome

was established by Colbert, with the practical assistance of Charles Errard (q.v.), its first director. By the study of the antique the student perfects himself in form and line and attains that skill in drawing and composition for which the Ecole has always stood, even to the detriment of color, and which, more than any other factor, has influenced French art. The site of the Academy since 1803 has been the Villa Medici, on the Pincian Hill.

The courses in drawing, sculpture, architecture, engraving, gem cutting at the Ecole des Beaux-Arts are free to both men and women between the ages of 15 and 30. Foreigners, not being eligible for the Prix de Rome, are not subject to the age regulation. The student who passes the examinations in any one of the courses must already have had experience in some special branch of art. The whole system of teaching at the Ecole is by means of competitions, and the grade obtained in these marks the student's relative advancement. The outside ateliers are in charge of the professors or "patrons," and in order to enter these the student pays a small fee. Some of his work is required to be done *en loge*, but much may be worked up in the ateliers. The regular course is nominally from 8 to 10 years, but a student may remain as long or short a time as he pleases, provided he visit the school twice a year, in order to keep his name on the rolls. The whole number of students in the school is approximately 2000, most of whom are French. The number of Americans who enter is larger than that of any other foreign nation, and the influence of the Ecole on American art and artists has been very great. The teachers, of whom there are (1913) 31 in the Ecole proper and 17 in the ateliers, besides the director (in 1914 Léon Bonnat) and administrative officers, are selected from among the most celebrated French artists. But they are paid a purely nominal fee, the equivalent of \$240 in our money, for work which takes them two half days each week of the school year.

The Palais des Beaux-Arts, the home of the Ecole, on the Quai Malaquais, was begun by Debret in 1820 and finished by Duban in 1863. It contains a noted collection of copies of famous paintings, made by the winners of the Prix de Rome, casts of statues and models of ancient buildings, drawings by old masters, and the Hémicycle of Delaroche (q.v.). Consult: Delaborde, *L'Académie des Beaux-Arts* (Paris, 1891); Béraud, *Annales de l'Ecole française des Beaux-Arts* (Paris, 1828); Montaiglon, *Mémoires pour servir à l'histoire de l'Académie Royale de Peinture et de Sculpture depuis 1648-1664* (ib., 1853); Vitet, *L'Académie Royale de Peinture et de Sculpture, Etude historique* (ib., 1861); Lenoir, *Histoire des arts en France* (ib., 1811); Penarun, Roux, and Delaire, *Les architectes élèves de l'Ecole des Beaux-Arts* (ib., 1895); *Architectural Record* (Beaux-Arts No., January, 1901); Flagg, "Ecole des Beaux-Arts," *Architectural Record*, vol. iii.

ÉCOLE DES FEMMES, á'kôl' dâ fâm, L' (Fr., The School of Wives). A five-act comedy by Molière, produced at the Palais Royal, Dec. 26, 1662.

ÉCOLE DES MARIS, dâ má'rê', L' (Fr., the School of Husbands). A three-act comedy in verse by Molière, produced at the Palais Royal in 1661. The general idea of the piece is borrowed from the *Adelphi*, of Terence, and details

are taken from Boccaccio and probably from Lope de Vega's *Discreta enamorada*.

ÉCOLE POLYTECHNIQUE, pól'ték'nèk' (Fr., Polytechnic School). See MILITARY EDUCATION.

ECOL'OGY, or ECOL'OGY OF PLANTS (from Gk. οἶκος, oikos, house + -λογία, -logia, discourse, from λέγειν, legein, to say). That division of botany which has to do with the mutual relations between plant organisms and their environment. Until recently the subject matter of ecology has not been systematically treated, although certain phases of the subject, such as pollination, seed dispersal, protection, symbiosis, have been for some time grouped together and denominated "biology," especially by German authors, as Kerner (1887), Wiesner (1889), and Ludwig (1895). The first to treat ecology systematically was Warming, of Copenhagen, who in 1895 gave a résumé of the ecological factors and their influence and discussed the ecological plant geography of the world, dividing plants into four groups, viz., hydrophytes, mesophytes, xerophytes, and halophytes (q.v.). In 1898 Schimper gave a much more extended treatment of the world's vegetation, but from a different point of view, namely, on the basis of temperature and humidity. In each subdivision the ecological factors are discussed, and the three types of climatic formations (forest, grassland, desert), and also, but very briefly, of the edaphic formations or groups of plant associations.

Ecology is even yet imperfectly organized, but at present two main aspects of the subject are recognized, and these are in their turn more or less subdivided according to different authorities. These aspects are: 1. Autecology, or the ecology of plants as individuals, i.e., the relation of these plants, their tissues and organs, to their environment, including the variations which result. This phase of ecology is often quite rightly regarded as inseparably connected with plant physiology. Autecology has two principal subdivisions: anatomical ecology, which deals with the origin, development, function and variations of plant tissues; and organographic ecology (usually termed simply organography), which concerns itself with the origin, development, and meaning of plant organs. 2. Synecology, the ecology of plant communities, investigates plants as they are associated in the vegetation covering the earth. It recognizes the fact that plants exist not only as individuals, but also members of communities that have an origin, a life history, and a more or less prolonged duration, and, further, that these communities are of various different ranks and develop as definite responses to various factors. It may be subdivided into physiographic ecology, dealing with the origin, development, and history of plant associations, their relationship to the local conditions, and the combination of these plant associations to form the larger plant communities known as plant formations; and geographic ecology, or ecological phytogeography, the study of the great forest, grass, and desert formations of the globe in relation to climatic factors. This latter subdivision is closely related to the geography and is conveniently discussed under the head of DISTRIBUTION OF PLANTS (q.v.).

Autecology, being concerned with the origin and meaning of the tissues and organs of plants, has led to the development of two methods of interpretation. The older, or teleological, may be termed the theory of purpose. It accounts for

the relations between structures and functions, either by special creation or by natural selection having caused specialized structures to arise, obviously adapted for certain ends. The latter modification of the theory may be termed one of adaptive response. For example, in very dry soil a very large root system is needed to obtain a sufficient water supply, and the roots are therefore believed to grow longer here because they are needed. Opposed to this view is the newer and more scientific method of interpreting these phenomena on the basis of mechanical causation and fortuitous variation. Plant structures are regarded as the result of responses to definite physical and chemical forces and quite as likely to be harmful or indifferent to the welfare of the plant as to be beneficial. That the latter appear to be more numerous is because plants possessing them are more likely to survive. These variations may also arise fortuitously, or rather as a response to unknown factors, while the factors may be either external or within the plant itself. Probably the correct standpoint is at neither extreme. Structures cannot be built nor functions carried on contrary to chemical or physical laws; but within certain limits there is perhaps room for successful variation, and hence for natural selection and the gradual inheritance of structures in relation to plant life.

Experiments show that some plants are rigid and some plastic. Rigid plants have commonly lived for ages in rigid habitats, as is especially true of desert plants. Plastic plants, on the contrary, often live in variable habitats, the best examples of all plastic plants being the amphibious species. It would seem as if permanence of habitat causes the development of rigid structures, and as if the great plasticity of such amphibious plants as *Ranunculus*, *Nasturtium*, *Polygonum*, *Proserpinaca*, *Sium*, etc., is the result of long life in variable habitats. The desert plant shows the natural selection of advantageous but rigid forms, while the amphibious plant shows the selection of the capacity to vary—a far subtler type of selection. The extreme views of some teleologists, who see a purpose in everything, must certainly be discarded, and it remains for the future to strike a proper balance between mechanical causation, adaptation, and adaptive response in ecology. At present, therefore, the ecologist should strive to ascertain the influence of external agents on plant form and should also seek to discover the advantages possessed by certain forms in the performance of the plant functions, but leave the exact relation between form and function to be determined by future investigation.

Physiographic ecology is the most recently developed subdivision of ecology, and deals with the origin and development of plant associations and their relationship to plant communities of a lower and higher order. It has long been evident that groups of associated species are also associated with a definite kind of habitat: e.g., lichens, mosses, and crevice plants are found upon rocks; pond weeds, water lilies, and bulrushes grow in shallow water; beech, maple, beech ferns, and maidenhair ferns thrive together in mesophytic forests. These groups of plants grow together because they thrive in similar conditions. Somewhat later it was also seen that the conditions of a particular habitat did not remain constant, but in the physiographic development of a region the habitats

passed through a series of more or less definite stages, owing chiefly to the processes of erosion and deposition, supplemented by the accumulation of humus, and with these changes of habitat there was a corresponding series of changes of the plant association, or, in other words, a definite *succession of vegetation*. Two general lines of succession are seen; for either the primitive associations are upon new land, rocks, or other xerophytic habitats, affording *xerarch successions*, or in the water, giving *hydrarch successions*; but in all regions of mesophytic climate the primitive associations are successively replaced by others slightly more mesophytic, until the series culminates in the most mesophytic association of which the region is capable. For example, this climax association in the northeastern United States, for both xerarch and hydrarch successions, is a deciduous mesophytic forest in which the beech and maple are usually conspicuous trees.

As already stated, the earliest and most useful ecological classification of plants and plant communities was into hydrophytes, mesophytes, xerophytes, and halophytes, or one based upon the water relations of the habitat. Some of the most recent advances in physiographic ecology have been in improved instruments and methods for measuring this water in its relation to plant growth. Plants, as a rule, obtain their water from the soil and lose it into the air. Ecologists therefore measure the amount of water available for absorption by plants above the point where the supply falls so low that they wilt, and at the same time determine the demand for water made upon the aerial parts of the plants by the evaporating power of the air, and the ratio between the two determinations gives with considerable accuracy the relative moisture of the habitat. More exact methods for measuring the other factors are being sought with some success.

The subject matter of anatomical ecology is not presented as such in this work. The purely morphological aspects are treated under ANATOMY OF PLANTS. Anatomical matter is also presented in connection with the topics HYDROPHYTE; XEROPHYTE; LEAF; ROOT; SYMBIOSIS. Organographic ecology will be treated in connection with the various organs of plants (see LEAF; STEM; ROOT; SEED; POLLINATION; also COLOR; DURATION; VEGETATIVE PROPAGATION) and with various plant forms. (See EPIPHYTE; LIANAS; SAPROPHYTE; SYMBIOSIS.) The topics treated in physiographic ecology, and to some extent in phytogeography, involve organographic material. Synecology will also be treated from the standpoint of topographic habitats (see BEACH PLANTS; BENTHOS; DUNE VEGETATION; HEATH; MEADOW; PLANKTON; ROCK PLANTS; RUDERAL PLANTS) as well as from the standpoint of the water relations (see HYDROPHYTE, MESOPHYTE, XEROPHYTE) and chemical relations of the soil. (See HALOPHYTE.) The ecological aspects of geographic botany are presented under DISTRIBUTION OF PLANTS; ALPINE PLANT; DESERT VEGETATION; FOREST; GRASSLAND; THICKET.

ECONOMIC ASSOCIATION, AMERICAN (Lat. *œconomicus*, from Gk. *οικονομικός*, *oikonomikos*, relating to the management of a household, from *οικονομία*, *oikonomia*, management of a household, from *οἶκος*, *oikos*, house + *νόμος*, *nomos*, law). An organization formed in 1885 and composed mainly of persons interested in the study of political economy or the economic phases of political and social questions. In 1913 it had about 2600 members, made up of teachers of political economy and related subjects, and business men, journalists, lawyers, and politicians interested in the theories of political economy and their application. Its chief feature is its annual meeting, which usually takes place in the last week in December, a convenient city being selected in the East and West in alternate years. The publications of the association include: *Publications of the American Economic Association* (1st series, 1886-97), consisting of reports of annual meetings and of monographs on economic subjects; *Economic Studies* (1896; 1897); *Publications* (2d series, 1897-99; 3d series, 1900-10). From 1908 to 1910 the association published a quarterly *Bulletin*, devoted to current notes, and in 1911 it published the *American Economic Review*, a quarterly journal holding an important place among the periodicals of economic science.

ECONOMIC CRISIS. See CRISIS, ECONOMIC.

ECONOMICS. See POLITICAL ECONOMY.

ECONOMICS, HOME. See HOME ECONOMICS.

ECONOMIZERS, or FEED-WATER HEATERS.

A name given first in England to a device to utilize the heat of the burned or heated gas in the flue or passage between a boiler and its chimney, so as to preheat the feed water which is to be introduced into the boiler. After passing through the boiler flues the furnace gases still retain considerable heat, which ordinarily escapes up the chimney. The economizer is so placed that it receives these gases and extracts a portion of the heat remaining in them. It consists of a series of tubes, made up in sections, connected together and placed in a chamber through which the gases from the boiler pass to the chimney. The feed water is forced through the tubes while the hot gases circulate around them. In most of the best forms of economizer a provision is made to scrape the soot or tarry deposit from the ex-

terior surfaces of the heating tubes. This may be power-driven and work continuously or may be operated by hand and intermittently. The scraping attachment adds enormously to the effectiveness of the feed-heating process, as the coating of sticky soot and the flue dust is a nonconductor of heat. Economizers are most effective in securing a saving of fuel in boilers and settings which are so designed that the heating surfaces of the boiler proper do not abstract from the gases and products of combustion as much heat as they might do. Such waste is caught and utilized in the economizer. Provision must be made to prevent excessive pressure from being generated in the economizer and injury from scale and corrosion. The name has also been applied, but less correctly, to a device for preheating the air for combustion in the boiler furnace.

ECONOMY. A village in Beaver Co., Pa., 17 miles northwest of Pittsburgh, on the Ohio River and on the Pennsylvania Railroad (Map: Pennsylvania, A 6). It was founded by the "Harmonists" in 1825, after their return from Indiana. Pop. (township), 1900, 1062; 1910, 860. See HARMONISTS.

ÉCORCHÉ, á'kór'shá' (Fr., flayed). A figure in which the muscles are represented, stripped of the skin, for purposes of art study. From a portion of the figure the upper muscles are also removed so as to exhibit those which lie nearer to the bone. Ancient examples of the subjects survive in the statues of Marsyas flayed by Apollo. Michelangelo is said to have made an écorché of exaggerated dramatic action. The examples most commonly used are those by the sculptor Houdon (q.v.), representing the figure in repose, and by the anatomist Salvage, in which the figure is depicted in violent action, not unlike the Borghese gladiator. Figures of this kind can now be procured both in plaster and papier-maché, and few artists' studios are without them.

ÉCORCHEURS, á'kór'shēr', LES (Fr., the flayers). Lawless bands infesting the rural districts of France and Belgium during the Hundred Years' War. They are first heard of in 1435, when, led by Villandras and Crabannes the Bastard, they began to rob, murder, and strip all unprotected wayfarers.

ÉCOSSAISE, á'kó'sáz' (Fr., Scotch). A dance of Scottish origin. It was written in 3-2 or 2-4 time and played upon the bagpipes. The modern *écossaise* is a species of contredanse in quick 2-4 time. Schubert wrote several *écossaises* for the piano.

ÉCRASEUR, á'krá'zēr' (Fr., crusher). A long steel instrument, invented by a French surgeon Chassaignac, and consisting of a fine chain, which, passed round any structure—the pedicle of a tumor, e.g.—gradually constricts it and finally crushes its way through it by means of a screw or rack for tightening the chain, controlled at the end of the handle. A wire may be substituted for the chain. The advantage of this instrument over the knife is that it causes little or no bleeding, the torn vessels spontaneously contracting and closing. The galvanic écraseur is even more effective in this respect. This instrument permits the wire loop to be heated to incandescence, thus cauterizing and sealing up blood vessels in its passage through the tissues. It is specially applicable for the removal of polypi and certain tumors.

ECSTASY (Lat. *ecstasis*, from Gk. *ἐκστασις*, *ekstasis*, displacement, astonishment, from *ἐξιστάειν*, *existanai*, to displace, from *ἐκ*, *ek*, out + *ιστάειν*, *istanai*, to stand). A state of consciousness (q.v.) characterized by intense emotional excitement, concentration of attention, and loss of self-control. There are many grades of ecstasy, from overpowering joy or grief to a temporary frenzy closely resembling mania. In the Neoplatonic philosophy of the early Christian centuries, ecstasy denoted a seizure or rapture in which the individual was supposed to transcend the distinction of subjective and objective, to come into direct union with God, and to know the ultimate nature of things. The ecstatic state of mysticism is somewhat similar. It is intended to liberate the soul from the body, to bring inspiration, and to induce the contemplation of supernatural objects. The most common form of ecstasy results from overmastering religious sentiments. Religious ecstasy has appeared from time to time, especially in the Middle Ages, as a widespread epidemic, leading to the most extravagant actions in whole groups of individuals. The term "ecstasy" is also used in mental pathology to denote an abnormal mental condition resembling the catalepsy of deep hypnosis. There are, however, two points of difference. In ecstasy, consciousness is not lacking, the mind being rather dominated by a single idea, and there is subsequent memory of the ecstatic state. Consult Galton, *Inquiries into Human Faculty* (London, 1883). For illustrations, see CONVULSIONARIES; DANCING MANIA; TERESA, SAINT.

EC'THESIS (Neo-Lat., from Gk. *ἐκθεσις*, *ekthesis*, exposition, from *ἐκ*, *ek*, out + *θέσις*, *thesis*, position, from *τίθειναι*, *tithenai*, to place). The name given to an edict issued by the Emperor Heraclius, in 638, for the purpose of settling the troubles caused by Monothelitism. It confirmed the monothelitic doctrine and failed of its object. It was annulled by Constans II in 648. See MONOTHELITISM.

ECTHYMA (Neo-Lat., from Gk. *ἐκθύμα*, *ekthyma*, pustule, from *ἐκθύειν*, *ekthyein*, to break out, from *ἐκ*, *ek*, out + *θύειν*, *thyein*, to rush). A pustular affection of the skin, an eruption, in which yellowish, flat pustules occur which often reach the size of a pea and have a red, slightly elevated, hard base. In the course of 2 or 3 days after the appearance of the pustule, it gains its full size, and after 7 to 10 days it is replaced by a scab, which adheres firmly to the base, and is somewhat concave. On its removal, a deep red mark, a new scab, an ulcer, or a healed scar remains. There is no premonitory or prepapular stage. It thus resembles impetigo (q.v.), as well as in being due to pyogenic cocci. It occurs only in debilitated people, especially in cases of chronic alcoholism, cachexia, in delicate and poorly nourished children, etc., and is particularly apt to occur in vagrants and in inmates of jails and almshouses. It also occurs in cases of syphilis, variola, glanders, diabetes, and nephritis. The *Staphylococcus pyogenes aureus*, *albus*, or *citreus* is the causative bacillus. The lesions are inoculable, and may appear when the patient has scratched the bites of fleas, lice, etc. Treatment must be directed to renovating the system with proper food, habits of cleanliness, and general hygiene, bitter tonics, saline and alkaline laxatives, and diuretics. The crusts should be removed with antiseptic washes, and the areas

treated with iodoform, carbolic acid, or bichloride of mercury, resorcin, boric acid, or salicylic acid.

EC'TODERM (from Gk. *ἐκτός*, *ektos*, outside + *δέρμα*, *derma*, skin), or **EPIBLAST**. The outer cellular layer of the embryo. See **EMBRYOLOGY**.

EC'TOPARASITE. A parasite living upon the surface of its host. Common examples are found among the various mildews growing upon the surfaces of leaves. Branches of these parasitic fungi may pierce the epidermal cells. See **PARASITE**; **PLANT PATHOLOGY**.

EC'TOPLASM. See **CELL**.

EC'TOR, or **HECTOR**. 1. The father of Sir Kay and foster father to King Arthur, in the Arthurian legends. 2. The brother of Sir Launcelot, in the Arthurian legends, after that knight's death, made an expedition to the Holy Land, where, on Good Friday, he met his death.

EC'TOTROPHIC. See **MYCORHIZA**.

EC'TOZO'A (Neo-Lat. nom. pl., from Gk. *ἐκτός*, *ektos*, outside + *ζῷον*, *zōon*, animal). A term in contradistinction to **Entozoa**, designating those parasitic animals which live upon the external parts of other animals, as lice, ticks, etc. Such as the entomostracous crustaceans, the fishes, these last being called more particularly **Epizoa**. See **ENTOZOA**.

ECTROPION (Neo-Lat., from Gk. *ἐκτρόπιον*, *ektropion*, everted eyelid, from *ἐκ*, *ek*, out + *τρέπειν*, *trepein*, to turn). A term applied to eversion of either eyelid exposing a portion of the conjunctiva, the mucous membrane that lines the inner surface of the lids. The lower lid is the more frequently affected. The exposed conjunctiva becomes red and thickened; there is an overflow of tears, causing an irritation and eczematous condition of the skin of the lower lid. Inflammation of the conjunctiva covering the eyeball, and sometimes of the cornea, may result from inability to close the lids. Ectropion may be caused by cicatricial contraction after burns and wounds ("cicatricial ectropion"); by paralysis of the facial nerve, causing drooping of the lower lid alone ("paralytic ectropion"); by the relaxation of skin and muscles occurring in old persons and affecting only the lower lid ("senile ectropion"); by spasmodic contraction of the orbicularis muscle ("spasmodic ectropion"); and by long-continued inflammation of the eyelid. Proper bandaging and the application of nitrate may cure in some cases; in other cases, operative treatment is necessary. In the cicatricial variety of ectropion, operation is the only effective remedy; in the paralytic form, electricity is generally sufficient.

ECTYPE (Lat. *ectypus*, Gk. *ἐκτύπος*, *ektypos*, from *ἐκ*, *ek*, out + *τύπος*, *typos*, figure). In architecture, a cast in relief of an ornamental design, produced from a mold or else an embossed copy of such a design. The term is also applied to a figured copy of an inscription.

ECUADOR, *ék'wá-dór*, *Sp. pron. á'kwá-dór'* (*Sp.*, Equator, so called because the country is crossed by the equator) (Map: America, South, B 3). A republic of South America, situated on the west coast of the continent and bounded on the north and east by Colombia, on the south by Peru, and on the west by the Pacific Ocean (see accompanying map). The area of Ecuador is about 118,627 square miles; it cannot be stated with accuracy, and there are

pending boundary disputes with Peru and Colombia, the settlement of which has been left to the German Emperor. The Galápagos Islands in the Pacific belong to Ecuador and are included in the above statement.

Topography. Ecuador may be divided into three physiographic regions: the coast, the Andean highland, and the eastern plains. The coastal region includes a strip of varying width, but averaging about 80 miles between the base of the Andes and the Pacific shores. It is crossed by several small rivers and by mountain spurs of the Andes. The highland region is defined by two parallel ranges or cordilleras connected by a number of mountain knots which divide the plateau between them into 10 basins, and traversing the country in a direction from north to south. (See **ANDES**.) Between the parallel ranges and their connecting ridges lie elevated basins, the centres of agriculture and population, which have an average height of about 8000 feet. East of the Andes the surface falls rapidly to the vast montaña or forests of the Amazonian plains. Ecuador is watered by many streams, which flow either into the Pacific or the Amazon. Those of the latter system are the more important and include the Napo (with its affluents, the Aguarico and Curaray), the longest river of Ecuador; the Putumayo, Pastaza, Morona, and Santiago. Most of them, being interrupted by rapids, are navigable but for short distances. The western rivers are of little consequence. The chief among them are the Mira and Esmeraldas. In the south the Guayas reaches the Gulf of Guayaquil through a long estuary. Lakes are numerous, but mostly small.

Climate. Ecuador has naturally a tropical climate, which, however, is considerably modified by the great elevation of the surface. In the low coast regions and the plains of the eastern portion, as well as in the deep river valleys, the climate is hot and rainy, the annual average temperature seldom falling below 80°. To the south of the Gulf of Guayaquil, however, the west coast desert begins. The most salubrious portions of the country are the elevated valleys of the Andes, lying at an altitude varying between 7500 and 9000 feet, where the temperature is moderate and fever almost unknown; and perpetual spring may be said to reign. Owing to their tropical situation, the snow line of the Ecuador mountains is very high, and human habitations are met with at 13,360 feet. Generally speaking, there are two seasons: the rainy season or winter, lasting from December to May, and the dry season, from June to November. Only in the elevated valleys, however, are the seasons marked with distinctive regularity.

Flora. The flora of Ecuador does not differ essentially from that of other western countries of South America, and resembles that of Colombia and Peru. In the lower portions, in the east and on the foothills, the vegetation is purely tropical. The forests of cabinet woods and of medicinal plants occupy a considerable portion of the territory. Above 6000 feet the vegetation is more northern, while above 10,000 feet trees are seldom met with, and the vegetable life consists of shrubs and coarse grasses.

Fauna. The fauna includes the common South American species, such as several varieties of monkey, the jaguar, tapir, llama, vicuña, alpaca,

etc. Birds, which include the condor and a large number of humming birds which are restricted to individual volcanic cones, are represented in numerous species.

Geology and Mineral Resources. The Andes contain Archæan gneisses and granites and sedimentary strata of Paleozoic and Mesozoic age, all closely folded and broken in many places by eruptions of volcanic rocks. The coast and the eastern plains are flooded by Cretaceous and Tertiary strata.

Very little has been done to develop the mineral resources of Ecuador, but their value is known to be very great. In the Province of Esmeraldas there are placer deposits of gold along the Santiago, Uimbi, and Cochabibi rivers, which are worked by hydraulic methods, and near Zaruma, Province of Oro, gold quartz is mined by an American company. The export of gold in 1903 was over \$700,000, but in 1910 it was only a little more than \$250,000. Copper, iron, coal, and petroleum are believed to occur in quantities to warrant exploitation. Platinum is found in the Esmeraldas washings, and a small amount of silver is exported.

Agriculture. The resources of Ecuador are considerable. The soil is of singular fertility and produces a large variety of crops. The principal product is cacao, which is cultivated chiefly in the provinces of Manabí, Guayas, and Oro; its production has been steadily rising; the exports of 1911 amounted to 39,500 metric tons and the value of the exports approximately \$9,000,000. Next in importance is coffee, which is cultivated in several districts, the value of the exports being approximately \$700,000 in 1911. The conditions for sugar cultivation are very favorable, and the industry is gradually extending. Tobacco, ivory nuts, rice, Indian corn, as well as the common cereals, such as wheat, barley, oats, and a number of medicinal and industrial plants, are also raised for the home market, as well as for export. The rubber tree abounds, and the collecting of rubber and planting of rubber trees is a growing industry; in 1911 the export of rubber was nearly \$1,000,000 in value. The cattle and sheep holdings are large, and considerable alfalfa is cultivated. Cheese is a staple food.

Manufactures, Commerce, and Transportation. With the exception of some coarse fabrics for native consumption, and straw braid used for the manufacturing of Panama hats and other straw articles, Ecuador has hardly any manufactures. The commerce, although steadily increasing, is as yet unimportant. The exports consist chiefly of cacao, vegetable ivory, India rubber, coffee, Panama hats, and rubber. Some gold is also shipped. The exports increased from 14,052,514 sucres (48.7 cents) in 1893 to 26,115,714 in 1911. The imports, consisting mostly of textiles, metal ware, and necessities of life, rose during the same period from 10,052,163 sucres to 23,240,133 sucres. The trade is mostly with France, Germany, Great Britain, and the United States. The commerce with the United States has increased as follows: Imports from Ecuador in 1890, \$836,437; in 1913, \$3,037,689. Exports from the United States in 1890, \$903,159; in 1913, \$2,553,785. The United States imports most of Ecuador's rubber and a considerable portion of its cacao, and exports to it railway supplies and foodstuffs. The chief ports are

Guayaquil, Manta, and Esmeraldas. The mountainous surface of the country is unfavorable to the development of transportation facilities. The roads are mostly for pack animals, being almost impassable during the rainy season. The chief road runs from Quito (q.v.), the capital, towards Guayaquil and the ocean. Of open railway lines Ecuador has only about 500 miles, of which the line from Durán (opposite Guayaquil) to Quito is about 375 miles; this line in 1912 was in operation to within 15 miles of Quito. There is telegraph communication between Quito and Guayaquil, and also with Colombia, while Guayaquil has cable connection with Panama and Peru. The length of the land telegraph lines in 1910 was 3400 miles with 60 telegraph stations. Telephonic systems are in operation in Quito and Guayaquil.

Government. The constitution dates from 1830 and has been frequently altered. The present constitution was adopted in December, 1906. The executive authority is shared by the President with a responsible ministry. The President is elected directly for a period of four years. The Congress consists of two houses. The members of the Senate (two for each province) are elected directly for four years. The House of Representatives consists of members elected directly for two years, at the rate of one deputy for every 30,000 inhabitants, with a supplemental deputy for every additional 15,000 inhabitants or more. The Indians, being practically in a condition of slavery, are unrepresented. Congress meets annually, at Quito, on August 10, but can be summoned for an extra session by the President. The voting franchise is restricted to every male citizen of 21 years of age who is able to read and write. The local administrators, from the governors of the provinces down to the lieutenants of the parishes, are all appointed by the President and removed at his discretion. For administrative purposes Ecuador is divided into 16 provinces, besides the Galápagos Archipelago, which is administered by a territorial chief. For the administration of justice there are a supreme court of five judges appointed by the Congress, six superior courts or courts of appeal, whose judges are also appointed by the Congress, and a number of commercial and other inferior courts.

Army and Navy. For military defense Ecuador has a standing army of about 3800 men and a national guard about 100,000 strong. The navy consists of a torpedo boat and a transport. For National Coat of Arms, see Colored Plate in article HERALDRY. For National Colors, see Colored Plate of FLAGS.

Finance. The revenue of Ecuador is derived mostly from customs duties (about 70 per cent from this source) and to some extent from taxes on real estate and from government monopolies and property. The budget for 1913 estimated the revenue at a sum equivalent to \$9,921,000 in United States currency, and the expenditure at a like sum. Ecuador's share of indebtedness at the dissolution of the Republic of Colombia in 1830 amounted to £1,824,000 (\$3,883,000). In 1854 the bondholders finally secured from Ecuador a formal recognition of its debt. In 1867 payment on the debt ceased, and the arrears amounted in 1891 to £428,640. By an arrangement with the creditors in 1892 the principal was reduced to £750,000, which sum was afterward further reduced. In 1904 the entire foreign debt amounted to 8,566,000 sucres, held

entirely by the Guayaquil and Quito Railway Company. In 1911 a new loan of 3,000,000 sucres was contracted with Speyer & Co., of New York. The total indebtedness was stated in 1914 at 40,625,000 sucres, equivalent to \$19,780,000 in United States currency. Ecuador adopted the gold standard in 1900. The silver coinage has been almost entirely superseded by gold. The circulation in 1910 was: gold, 5,087,000 sucres; silver, 2,783,000; paper, 9,835,000. The Banco del Ecuador and the Banco Comercial y Agrícola, with a combined capital of 8,000,000 sucres, issue notes for circulation, which amount now to about 10,000,000 sucres. There are two other leading banks.

Weights and Measures. The Law of 1898 established the gold standard with a gold coin, the *condor*, containing 7.3224 grams of fine gold and equivalent in value to the English pound sterling; the silver *sucra*, one-tenth of the value of the condor and the unit of value (value, 48.7 cents in U. S. currency); and nickel and copper coins, fractions of the sucra. The metrical system, adopted in 1856, is used only in official publications. The current measures and weights are essentially the same as in the United States. The unit for linear measure is the vara (yard); for weight, libra (pound); for capacity, fanega (4.44 cubic feet).

Education. Elementary education is gratuitous and obligatory. There are a university at Quito and a number of secondary schools; the elementary schools number over 1000 and have an attendance of about 70,000. Education is at a low ebb.

Population. The population (official estimate in 1900) by provinces is given as follows:

Carchi.....	40,000	Bolívar.....	43,000
Imbabura.....	68,000	Los Ríos.....	32,800
Pichincha.....	205,000	Oro.....	32,600
León.....	109,600	Guayas.....	98,042
Tungurahua.....	103,033	Manabí.....	64,123
Chimborazo.....	122,200	Esmeraldas.....	14,600
Cañar.....	64,014	Oriente.....	80,000
Azuay.....	132,400	Galápagos Islands	2,000
Loja.....	66,000		

Total.....1,277,800

In 1910 the population was estimated at 1,500,000. The population of the territory of the Galápagos is given as 400. Principal cities: Quito, 70,000; Guayaquil, 80,000; Cuenca, 30,000 (these being estimates for 1910). The whites number about 100,000; those of mixed origin about 400,000; while the remainder consists of Indians and a small number of negroes. The prevailing language of Ecuador is a Peruvian dialect. There are said still to be communities of pure Quichuas. The Cayapas and the Tochi are probably descended from the ancient conquered peoples of Ecuador. The civilized Indians, belonging generally to the Quitus race, form the great laboring class. In the Amazonian valleys several tribes—the Oregones, Encabell dos, etc.—are related to those of western Brazil. In the east, too, generally are found the Jivaros, Zaparo, Abiquira, and other peoples who are supposed to be of the Tupi and the Carib races. They were formerly progressive and prosperous, but have greatly deteriorated since the expulsion of the Jesuits in the latter part of the eighteenth century.

History. The history of Ecuador up to the coming of the Spaniards is involved in obscurity. Whatever there was among the natives

in the way of writings and records which dealt with their earlier experiences the fanatical missionaries converted into ashes. There is, however, among the Indians the tradition that centuries prior to the coming of the Europeans there had existed a strong kingdom in what is now Ecuador, called Quito, which in the tenth century was overthrown by a coast people known as the Caras. The kings of the Caras occupied the throne until 1475, when, after a long and desperate resistance, they succumbed to the Inca armies of Peru, led by Huayna Capac the Great, who added Ecuador to his dominions, establishing his capital at Quito. At his death his territories were divided between his two sons, Huascar, who held Peru, and Atahualpa, who reigned at Quito. They soon fell out, and civil war after war against each other, being at last overthrown in 1532.

It was at this junction that Pizarro, having with a handful of men embarked upon the conquest of the realm of the Incas, arrived on the scene. He seized Atahualpa at Cajamarca, and in 1533 he put him to death. The vast territories of the unfortunate Inca were added to the Spanish Empire. They were erected into a presidency, with Quito as capital, and subordinate to the Viceroy of Peru. It remained thus until the outbreak of the great revolution which freed South America from Spanish rule.

The defeat of the Spaniards in the battle of Pichincha in 1822 liberated the Province of Quito, which joined New Granada and Venezuela in forming the Republic of Colombia, organized under the auspices of Bolívar. In 1829 Venezuela withdrew from the confederation, and in 1830 the independent Republic of Ecuador was constituted. Then there followed a number of struggles between rival political leaders, of whom the chief were Flores and Rocafuerte, which demoralized the country, destroying all security of person and fortunes. The Ecuadorians, however, were not content with fighting among themselves; they interspersed their local quarrels with wars against their neighbors, Peru and Colombia. In 1845 Vicente Roca became President, and one of the distinguishing acts of his régime was the convention with England for the abolition of slavery.

From 1850 the struggle between the Clerical and Liberal parties became bitter. In that year Diego Noboa, of the Clerical party, having seized the presidency, was overthrown by the Liberals under General Urbina. The power rested with the latter party till 1860, when there occurred a general breaking up, with several leaders claiming the presidency. The Clericals finally triumphed, electing Dr. Garcia-Moreno, who became distrusted before the end of his term. Forcing his own election a second time in 1869, he endeavored to establish a religious despotism, but was assassinated in 1875. Numerous revolutions took place during the next twenty years, and in 1895-96 a new civil war broke out between the two parties, resulting in a Liberal triumph. The Liberal leader, General Eloy Alfaro, assumed dictatorial powers, and was elected to the presidency in 1897. He pursued an active anti-Clerical policy, and his term was disturbed by various Clerical uprisings, one of which caused troubles with Colombia (1899). In 1901 General Leonidas Plaza, the administration candidate, was elected to the presidency and quietly assumed office (August 31). His anti-Clerical

policy continued that of his predecessor; civil marriage and divorce were introduced, and in 1904 all religions were made equal before the law. The establishing of new monasteries and convents was forbidden in the interest of the economic conditions of the country, and all church property was finally declared to be the property of the nation. In 1905 the Clericals were successful in electing to the presidency Lizardo García, a wealthy merchant, who was overthrown in January, 1906, by an uprising led by ex-President Alfaro, who was declared supreme dictator by the army. In 1911 Alfaro secured the election of his candidate, Emilio Estrada, who was unpopular, but who assumed the presidency after a popular tumult, marked by the assassination of a number of leaders, which secured the written abdication of Alfaro. The death of Estrada again plunged the country into revolution. General Plaza took charge of affairs and General Montero issued a *pronunciamiento* against the government (December, 1911). About 1000 revolutionists were at Guayaquil by a strategy of which the British and United States consuls intervened and arranged a capitulation. This was violated before completion and General Montero was shot, while Alfaro, who had joined the revolutionists, and a number of other leaders were taken from prison and assassinated by a mob at Quito. General Plaza, the provisional head of the government, was again elected constitutional president in 1912. He took steps to reestablish the credit of the country and in 1913 signed a contract for cleaning up Guayaquil (q.v.). Late in this latter year new revolts took place and continued in 1914, considerable fighting at Esmeraldas, which was between the hands of the rebel and the government forces. The present good condition of Ecuadorian finances is largely due to the initiative and ability of the American railway builder and financier, Mr. Archer Harman, who has taken a deep interest in Ecuador's welfare.

ECUMENICAL COUNCIL. See COUNCIL.

ECZEMA (Neo-Lat., from Gk. *ἐκζεμα*, *ekzema*,

skin disease, from *ἐκ*, *ek*, out + *ζειν*, *zein*, to boil). An inflammatory disease of the skin characterized by a number of cutaneous lesions, such as macules, papules, pustules, vesicles, scales, and crusts, generally with exudation of serum and intense itching. It is the commonest skin disease and represents from one-half to one-third of all cutaneous affections. It may be acute or chronic in its course. It is divided into four elementary types—erythematous, papular, vesicular, and pustular; but there are several secondary types, such as squamousum, rubrum, parasiticum, seborrhœicum, marginatum, neuroticum, diabetorum, intertrigo, fissum, verrucosum, and sclerosum. Among internal causes of eczema are alcoholic beverages, dietetic errors, medicines, visceral disorders, gout, scrofula, and neurasthenia. From the belief that a "humor of the blood" caused eczema, it has been commonly called "salt rheum." Among external causes are scratching, heat, cold, friction, and pressure, acids and poisons, and animal and vegetable parasites. Treatment must be directed to the particular form of the disease. In all cases strict dietetic and hygienic rules must be followed; causes must be removed or treated with a view to removal: laxatives, iron tonics, bitter principles, and electricity are used. Locally, antiseptic powders, zinc, salicylic acid, permanganate of potash, tar, ichthyol, thymol, oil of cade, bismuth, mercury, lead, carbolic acid, sulphur, and green soap are among the drugs used. Each case must be intelligently studied if treatment is to succeed.

EDAM, Dutch pron. á-dám'. A town of the Netherlands in the Province of North Holland, near the Zuyder Zee, 12 miles north-northeast of Amsterdam (Map: Netherlands, D 2). Its Reformed church of St. Nicholas, with large painted windows, is among the finest in North Holland. The town is chiefly known through its cheeses and its cheese fair. Other industries are shipbuilding, leather manufacture, rope and sail making. Pop., 1900, 6444; 1910, 6623.

EDAM CHEESE. See CHEESE; CHEESE MAKING.

EDAPHIC (from Gk. *ἐδαφος*, *edaphos*, foundation, soil). In botany the term is used with reference to local influences, especially those that reside in the soil, that affect the growth and distribution of plants. The soil itself exerts such influences through (1) its chemical composition and (2) its physical nature. The latter is probably the more important. For the size of the soil particles and their looseness or compactness determine the amount of water the soil will absorb and retain. The former seems of importance only where certain salts are present in excess, as in alkaline depressions, salt marshes, or where acids are particularly abundant, as in certain types of swamps. The amount of humus in a soil is important in changing both the chemical and the physical nature of the soil.

Edaphic influences, being local, are contrasted with climatic, which are widespread; e.g., a cypress swamp is an edaphic, and a desert is a climatic, area. See ECOLOGY; DISTRIBUTION OF PLANTS.

EDDA. A title applied to two distinct works in Scandinavian literature, the *Edda* ascribed to Sæmund the Wise and the *Edda* of Snorri Sturluson. They are also called respectively the Poetical and the Prose, and the Elder and

the Younger Edda. The latter of these, to which alone the name Edda is properly applied, treats of Scandinavian mythology and of the language and modes of composition of the ancient skalds (q.v.). Its original purpose was to serve as a guide for young poets. Accompanying this Edda are four grammatical treatises, which are frequently included in modern editions. They have also been published separately, with critical introductions and notes (Copenhagen, 1884-86). As its second name implies, the Prose Edda is ascribed to the Norse historian and politician Snorri Sturluson (q.v.), who flourished in the first half of the thirteenth century. Originally it consisted of three main parts: (1) *Gylfaginning* (the deception of Gylfi), in which various exploits of the gods and goddesses are related to a mythical Swedish king Gylfi, who is supposed to visit Asgard; (2) *Skáldskaparmál* (the language of poetry), in which an explanation is given of many of the figures of speech used by the skalds; (3) *Háttatal* (list of metres), a catalogue of the different kinds of metres used by the skalds. Snorri's treatment of the mythology is often inaccurate and is not free from contradictions. This is, however, in spite of its evident faults, one of the most important monuments of Old Norse literature. The Prose Edda was first published by Resenius in Copenhagen in 1665. This edition includes a translation into Latin by the editor and others. The next edition was published in Sweden (1746). The first modern critical edition is that of Rask, published at Stockholm in 1817. The most complete modern edition is the *Arna-Magnæan* (Copenhagen, 1848-37), in 3 vols., with a Latin translation and notes. Finnur Jónsson has edited both the Eddas, with German notes (1880-90). E. Wilken's *Die Prosaische Edda in Auszuge* (1877-82) contains the first two parts, with a German glossary. The standard German translation is Simrock's (1851). The *Gylfaginning* was translated into French by Bergmann (2d ed., 1871). The mythological part has been translated into English by Dasent (1842) and by Blackwell (in Mallet's *Northern Antiquities*). R. B. Anderson's version (1880) includes the narrative portion of the *Poetical Diction* and several minor parts.

The Elder Edda is a collection of mythological and heroic Scandinavian songs, 33 in all, the date of whose composition in their present form may probably be referred to different periods between the tenth and the thirteenth centuries. The view that assigns to them a great antiquity is no longer held by scholars. The arrangement of the whole is very unsystematic, and the text is in many parts corrupt. Vigfússon, in the *Corpus Poeticum Boreale*, vol. i (1883), tried to rearrange the parts, but his attempt is regarded as ingenious rather than convincing. These songs, which were discovered and first brought to the notice of European scholars in 1643 by Brynjólfur Sveinsson, Bishop of Skálholt, in Iceland, were incorrectly supposed by him to be the work of Samund the Wise (1065-1132). His application to them of the name Edda is also improper, as that title, which probably means "poetic guide," belongs only to the prose work. The etymology of the word that connects it with "great-grandmother" is no longer taken seriously. The unique manuscript in which the Elder Edda is contained is called the *Codex Regius* and is lodged in the Royal Library at Copenhagen. A splendid litho-

graphic facsimile edition, with a diplomatic text, was issued in 1891 under the editorship of Wimmer and Jónsson. A facsimile of a fragment of another manuscript of the Edda was published five years later by Jónsson. The collection was first published entire at Stockholm in 1818 by A. A. Afzelius, and at Copenhagen by the Royal Commission in 1777-1828, with a Latin edition, etc. Complete editions were also issued by Munch (1847), Lünig (1859), Möbius (1860), and Svend Grundtvig (1867). But all former editions have been superseded by that of Sophus Bugge (1867). Hildebrand's edition (1876) is accompanied by a valuable glossary by H. Gering (2 ed., 1896). Consult also: Detter and Heinzel, *Saemundar Edda* (2 vols., Leipzig, 1903); Sijmons and Gering, *Die Lieder der Edda* (2 vols., Halle, 1903-06), and Gering, *Vollständiges Wörterbuch zu den Liedern der Edda* (Halle, 1903), containing both text and vocabulary; Genzmer, *Edda, übertragen, mit Einleitungen und Anmerkungen, von A. Heusler* (Jena, 1912). In German the best rendering is Simrock's. Both Ettmüller and the brothers Grimm have translated portions. The latest German versions are due to Gering (3d ed., 1912) and Genzmer (1912). A Danish rendering of the mythical lays by Karl Gjellerup was issued in an illustrated edition in 1895. The standard Danish translation is Müller's (1871). There is a French rendering by E. de Laveleye (1866). The earliest English translation is Cottle's (1767). A complete English translation by Ben Thorpe was published in 1866; another translation was begun by Collingwood (London, 1908). Several of the lays are translated by R. B. Anderson in his *Northern Mythology* (1875). In the *Corpus Poeticum* an English rendering is given by F. Yorke Powell, in which the arrangement of Vigfússon's text is followed.

For a discussion of the question of the possible non-Scandinavian origin of the Elder Edda, consult Bugge, *Home of the Eddic Lays*, trans. by Schofield (London, 1899). For a general account in English of the scope of the Edda, consult W. Faraday, *The Edda* (London, 1902). For a comparative study of the language and grammatical forms, consult Noreen, *Geschichte der nordischen Sprachen besonders in altnordischer Zeit* (3d ed., Strassburg, 1913). See also SCANDINAVIAN AND TEUTONIC MYTHOLOGY.

ED'DOES. See COCO.

EDDY, CLARENCE (1851-). An American organist and composer, born at Greenfield, Mass. He studied under Dudley Buck in Hartford, counterpoint under Haupt, and piano under Loeschhorn in Berlin. In 1894 he was made organist of the First Congregational Church in Chicago, where he also was director of the Hershey School of Musical Art from 1875 to 1908. In 1908 he took up his residence in New York. Mr. Eddy's series of 100 organ recitals, with entirely different programmes, given in 1877-79, is one of the most memorable achievements in the history of American music. He composed organ music, translated Haupt's *Counterpoint, Fugue and Double Counterpoint* (1876), and published *The Church and Concert Organist* (1882-85), *The Organ in Church* (1887), etc.

EDDY, HENRY TURNER (1844-). An American scientist, born at Stoughton, Mass. He was educated at Yale University and Sheffield Scientific School and later took a further

scientific course in Berlin and Paris. After holding a professorship in mathematics, astronomy, and civil engineering at the University of Cincinnati (1874-90), and acting as dean of the academic faculty of that institution (1874-77, 1884-89), he became its president in 1890. He was also president of the Rose Polytechnic Institute at Terre Haute, Ind., from 1891 to 1894, when he accepted the chair of engineering and mechanics at the University of Minnesota. He became dean of the Graduate School of the latter university in 1906. His works include: *Analytical Geometry* (1874); *Researches in Graphical Statics* (1878); *Thermodynamics* (1879); *Neue Constructionen aus der graphischen Statik* (1880); *Maximum Stresses under Concentrated Loads* (1890); *Theory of the Flexure and Strength of Rectangular Flat Plates Applied to Reinforced Concrete Floor Slabs* (1913).

EDDY, MARY BAKER (c.1821-1910). The founder of Christian Science. She was born at Bow, near Concord, N. H. In 1843 she married Col. George W. Glover of Charleston, S. C., where she resided until his death. From that time Mrs. Eddy made her home in New Hampshire and Massachusetts. In 1877 she married Dr. Asa G. Eddy. Mrs. Eddy gives 1866 as the date when she discovered what she afterward presented to the world as the science of Christianity. She founded the First Church of Christ, Scientist (the "Mother Church"), in Boston in 1879 and opened the Massachusetts Metaphysical College there in 1881. She is most widely known as the author of *Science and Health with Key to the Scriptures*. The first edition of this work was published in 1875, and since then it has been often reprinted, with occasional revisions of its wording before her decease. It sets forth the Christian Science interpretation of the Holy Scriptures and this method of healing. Mrs. Eddy's followers believe that living in strict accord with Christian Science will not only improve their moral and spiritual condition, but will insure physical welfare. Mrs. Eddy's other publications are: *People's Idea of God* (1886); *Christian Healing* (1886); *Retrospection and Introspection* (1891); *Unity of Good* (1891); *Rudimental Divine Science* (1891); *No and Yes* (1891); *Church Manual* (1895); *Miscellaneous Writings* (1896); *Christ and Christmas* (1897); *Christian Science versus Pantheism* (1898); *Pulpit and Press* (1898); *Messages to the Mother Church* (1900; 1901; 1902); *The First Church of Christ, Scientist, and Miscellany* (1913). Mrs. Eddy died Dec. 3, 1910, at Newton, Mass., leaving the bulk of her estate to be used for extending the world's knowledge of the religion which she taught. Consult *Life by Wilbur* (4th ed., Boston, 1913). See **CHRISTIAN SCIENCE**.

EDDY, RICHARD (1828-1906). An American Universalist clergyman, born at Providence, R. I. During the Civil War he was chaplain of the Sixtieth New York Volunteers, and of this regiment he wrote a history. After 1877 he was president of the Universalist Historical Society and after 1887 editor of the *Universalist Register*. He published: *History of Universalism in America, 1636-1886* (1884-86); *Alcohol in History* (1887); *Universalism in Gloucester, Mass.* (1892); *History of Universalism, 120-1890, A.D.* (1894); *Life of Thomas J. Sawyer, D.D., and Caroline M. Sawyer* (1900). He was a

contributor to the first edition of the *New International Encyclopædia*.

EDDY, THOMAS MEARS (1823-74). An American clergyman, born in Newton, Hamilton Co., Ohio. He entered the Methodist ministry, joining the Indiana conference in 1842. For a term he was pastor at Jeffersonville, where he became intensely interested in prison reform. In 1854 he was agent for the American Bible Society. He was editor of the *Northwestern Christian Advocate* from 1856 to 1868. In 1872 he became one of the missionary secretaries of his denomination. In the meantime he held important pastorates in Baltimore and Washington, D. C. Consult *The Life of Thomas M. Eddy, D.D.*, by Charles N. Sims (New York, 1880).

EDDY, WILLIAM ABNER (1858-1909). An American meteorologist, born in New York. He took a preparatory course at the University of Chicago. Beginning experiments in kite flying in 1890, he gave special attention to problems of air currents and air layers, and in 1896 he first took pictures of the earth by controlling a camera attached to one of his kites, some of which attained a height of nearly 7000 feet. In 1903 he came to the conclusion, from the actions of an aeroplane model which he had released from a large flying kite, that eventually the aeroplane would be a practicable means of travel. He also investigated the relation of high-air temperature to that on the earth and constructed various devices to measure earth tremors.

EDDY CURRENTS. See **FOUCAULT CURRENTS**.

EDDYSTONE. See **LIGHTHOUSE**.

EDELFELO, a'del-felt, ALBERT GUSTAV ARISTED (1854-1905). A Finnish portrait, landscape, and genre painter, born at Helsingfors. He studied at the Academy of Fine Arts in Antwerp and then under Gérôme in Paris, where he lived many years. He first attracted attention with a portrait, "Pasteur in his Laboratory," but is at his best in studies of the life and scenery in his native country, painted with the freshness of vision of the North combined with a strong sense of the pictorial learned from the French. Among the best are: "Divine Service on the Seashore" (1882, Luxembourg Museum); "The Women in the Churchyard"; "Christ and the Magdalen," treated as a Finnish legend (both in Helsingfors Museum); and the "Laundry," which made a sensation in Munich in 1893. Edelfelt was very versatile and is also known as a water-color and pastel artist. He received a first-class medal in Paris in 1889 and was made Commander of the Legion of Honor in 1901.

EDELMAUN, a'del-mán, JOHANN CHRISTIAN (1698-1767). A German rationalist, born at Weissenfels. He studied theology at the University of Jena, resided for a time with Count Zinzendorf at Herrnhut, and participated in the translation of the Berleburg Bible. Soon after he turned weaver, donned a Mennonist smock frock, and continued authorship only at the request and with the support of interested friends. Having come to Neuwig, he was there compelled by the Count to draw up a confession of faith: and when this was printed, without his consent and in a garbled version, he retorted by publishing the true copy with annotations as an *Abgenötigtes, jedoch andern nicht wieder aufgenötigtes Glaubensbekenntnis* (1746). Perse-

cuted as a freethinker, he fled to Altona, where he lived in concealment, not venturing into Hamburg by day for fear of the derision of the workmen from the printing factories. In 1749 he went to Berlin, where, in 1752, though forbidding him to publish further, tolerated him, on the ground, it is said, that fools had to be endured. He was described as a choleric and laborious person. He was among the first German opponents of positive religion, which he denounced as superstition. His views were not new, but were proclaimed with a blasphemous emphasis which attracted brief attention. Among his other works are: *Moses mit seinen Lehren* (1740); *Christus und seine Lehre* (1741); *Die Gottlichkeit der Vernunft* (1742). An autobiography, edited by Klose, appeared in Berlin in 1849.

EDELWEISS, *edel-weiss* (Ger., noble white, from *edel*, noble + *weiss*, white), *Leontopodium alpinum*. An Alpine perennial woolly plant of the Composite family, found in Switzerland, the Tirol, Carinthia, Alpine Austria, and Siberia. It bears heads of flowers surrounded by woolly bracts and sage-green leaves. It is famous, not for its beauty, but because of its scarcity and the difficulty of obtaining it in its elevated haunts, and is so rare in Switzerland that several cantons protect it by law. It is readily cultivated in gardens in America and Europe. In Swiss poetry and legend it plays a prominent part.

EDEMA. See **CEDEMA**.

EDEN (Heb. *'eden*, delight). According to the biblical account, the first residence of man. On the supposition that the narrative in Genesis describes a real country, endless views have been brought forward in regard to the situation of Eden. In Ethiopic Enoch xxxii, 3, the "garden of righteousness" is placed in the northeast far beyond the Erythraean Sea. Josephus and several of the fathers conceived of the river of Eden as the earth-encircling ocean and looked for Eden itself somewhere between the Ganges and the Nile. Calvin, Huet, Bochart, and others have, with slight differences of detail, decided in favor of southern Babylonia, not far from the Persian Gulf; Reland, Calmet, Hales, Bunsen, Keil, in favor of Armenia, near the sources of the Tigris and Euphrates; and Le Clerc, in favor of the region near Damascus, while even Australia and the North Pole have been advocated. The description in Genesis (chap. ii) seems to assume the existence of a great river which forms the source of larger streams. The writer mentions four such streams—the Tigris, Euphrates, Gihon, and Pishon. The first two are well known, but it is not clear what he meant by the latter two. It has been supposed that he intended the Gihon for the Nile, as Josephus already has it (*Ant.* i, 1-3), and if it be recalled that many centuries later Arabic geographers supposed the Nile to have its rise in India, it would not perhaps be strange that the source of the Nile should have been unknown to this earlier writer. But it is by no means certain that he meant the Nile. For the Pishon, which "encompasses" the land of Havilah, some part of Arabia, the Arabian Sea has been suggested; and since the Persian Gulf is in cuneiform inscriptions called a river, it is not improbable that a writer who had only heard of southern Arabia should call the body of water flowing around it a river. Glaser and others have maintained that Pishon is the Arabian Wadi Faisan. The Karun has been claimed for

Gihon on the ground that Cush is probably a wrong pronunciation for Kash, the country whence the Kassites came. However that may be, the original habitat of man for the biblical writer is likely to have been in the same region in which mankind dwelt before the dispersion. It has been supposed that Edinn was the Sumerian name of the plain of Babylon, but this is doubtful, though the identification of Eden with Edinn may be admitted. A connection has also been assumed between Eden and Beth Eden (Amos i. 5), the Eden of Ezek. xxvii. 23, and the "Sons of Eden" of 2 Kings xix. 12. But in all of these passages it is probable that the Bit Adini of the Assyrian inscriptions is meant (see **ASSYRIA**), which can scarcely have had any relation to the Eden of Gen. ii. Of the vast literature on Eden, but little is of value at present. It will be sufficient to refer to Delitzsch's work *Wo lag das Paradies?* (1881), although his theory of the identification of Gihon and Pishon with two of the canals of Babylonia is not tenable. Consult also the commentaries on Genesis by Dillmann, Holzinger, Strack, Driver, and more particularly that of Gunkel (3d ed., 1910).

EDEN. A town in Hancock Co., Me., 35 miles (direct) southeast of Bangor, on the Maine Central Railroad, the Atlantic Ocean, and on the line of the Eastern Steamship Company (Map: Maine, D 4). Eden is situated on Mount Desert (q.v.) Island and it contains the village of Bar Harbor, the well-known summer resort. There are a hospital, public library, and a Federal building. Pop., 1900, 4379; 1910, 4441.

EDEN, GEORGE. See **AUCKLAND, GEORGE EDEN, EARL OF**.

EDEN, SIR ROBERT (1741-84). An English baronet, the last proprietary Governor of Maryland. He was the second son of Robert Eden, of Winderstone Hall, Durham. Before he was 16, he obtained a commission in the Royal Regiment of Artillery; in 1758 he was raised from cadet to ensign in the Coldstream Guards, and in 1762 he was promoted captain. He served in Germany during the Seven Years' War and soon after returning to England married the sister of Frederick, the sixth and last Lord Baltimore. His appointment as Governor of Maryland in 1768 was due to his family connection; but after his arrival in June, 1769, he displayed tact and ability in the stormy times which he came upon and endeared himself to the people by his prudence and kindness. The most serious controversy in which he held out against the people was that over the fees of public officers. In a proclamation of Nov. 24, 1770, he asserted that it was his prerogative to settle such fees, and although he maintained his position until the institution of the provisional government, the colonists blamed only his advisers without becoming embittered against him. The death of Lord Baltimore in September, 1771, weakened the proprietary government, for the loyalty of the colonists did not extend to the illegitimate son, Henry Harford, who became the next proprietary, and during the absence of their Governor, who went home to act as an executor of his brother-in-law's estate, great advances were made towards independence. He remained in the Colony until June 23, 1776, when, Congress having ordered his arrest for his correspondence with British officers, and Maryland having definitely committed herself to the principles of the Revolution

EDELWEISS, ETC.

1. ELM LEAF (*Ulmus Americana*).

1a. FRUIT, of the same Elm.

2. BLUE GUM SPRAY (*Eucalyptus globulus*).

3. CALADIUM or ELEPHANT'S EAR (*Caladium bicolor*) and spathe.

4. AN AFRICAN EUPHORBIA (*Euphorbia officinarum*).

5. EDELWEISS (*Leontopodium Alpinum*).

6. ELECAMPANE (*Inula helonium*).

and having virtually declared the proprietary government at an end, he escaped on a British war vessel. Shortly after his arrival in England he was created a baronet. During his term as Governor he had assumed the rôle of apologist for the Colony and had believed in its loyalty to the end. He returned to Maryland in 1784 on business, and died in Annapolis, on September 2 of that year. Consult Steiner, "Life and Administration of Sir Robert Eden," in the *Johns Hopkins University Studies in Historical and Political Science*, 16th series, nos. vii-ix (Baltimore, 1898).

EDEN, WILLIAM. See AUCLAND, BARON.

EDEN HALL, LUCK OF. See LUCK OF EDEN HALL.

EDENTATA, or **BRUTA** (Lat. nom. pl., toothless, from *e*, out + *dens*, tooth). An order of Mammalia, established by Cuvier, who remarked that, although brought together by a purely negative character, the Edentata have, nevertheless, some positive mutual relations, particularly in the great claws which approximate to the nature of hoofs; also in a certain slowness or want of agility, obviously arising from the peculiar organization of their limbs. He included among them, however, the monotremes, now entirely separated. The anteaters and pangolins are the only Edentata that are absolutely destitute of teeth; but none of the order have any teeth in the fore part of their jaws, and their teeth are comparatively imperfect in structure, being destitute of enamel and distinct roots; they grow from a distinct pulp, are all alike, and (except in Tatu) are not preceded by a set of milk teeth. The sloths alone subsist on vegetable food, the rest chiefly on insects or on animal substances in a decaying state. The Edentata form one of the smallest orders of mammals; its headquarters are in South America, but some species are found in Africa and southern Asia. All are clothed with coarse hair, which in the sloths and anteaters covers the body, in the pangolins is arranged into overlapping plates or scales, and in the armadillos is very sparsely scattered over the body, which is otherwise protected by dermal plates. The Edentata are generally ranked as the lowest of the placental mammals, not merely because of the condition of the teeth, but because the brain is small and poorly developed, the cerebrum not nearly covering the cerebellum and being perfectly smooth. The order is generally grouped in five tribes or suborders: the sloths (Tardigrada), which are characteristic of South America; the pangolins (Squamata), found only in Asia and Africa; the armadillos (Loricata), found from Texas southward in America; the true anteaters (Vermilinguia), found only in South America; and the aardvarks (Podientia), found only in Africa. No living Edentata are known in Europe. Consult: Rapp, *Anatomie Untersuchungen über die Edentata* (2d ed., Berlin, 1852); Flower, "Mutual Affinities of the Edentata," in *Proceedings Zoological Society of London* (London, 1882); Thomas, "A Milk Dentition in *Orycteropus*," in *Proceedings Royal Society of London*, vol. xlvii (ib., 1890); Klineckowström, *Zur Anatomie der Edentaten* (Jena, 1895); Windle, "Myology of the Edentata," in *Proceedings Zoological Society of London* (London, 1899); Beddard, *Mammalia* (ib., 1902); also authorities referred to under the various groups, as SLOTH, ETC. See Plate of ANTEATERS.

Fossil Edentata. Remains of fossil edentates have been found rarely in the Tertiaries of Europe and Africa. The centre of greatest development seems to have been South America, during ancient times as well as at present, though some imperfectly known forms, more nearly like the normal mammals in dentition, having incisor teeth on both jaws and the normal premolar and molar teeth, have been discovered in the Eocene deposits of North America. The paleontologic evidence does not support the hypothesis that the edentates represent primitive forms of mammals, but it does show that they have been derived by regressive evolution from higher normal eutherian types, and that they constitute a degenerate series of mammals, the exact origin of which is, however, unknown. See DEGENERATION AS A FACTOR IN EVOLUTION; EXTINCTION OF SPECIES.

No fossil form of the sloths (family Bradypodidae) or anteaters (Vermilinguiidae) has been found, but an extinct form (Mylodon darwini) presents characters intermediate between these two modern groups. They were mostly mammals of gigantic size, such as *Megatherium*, *Mylodon* (qq.v.), *Scelidotherium*, and *Megalonyx*, the remains of which are found commonly in the Pleistocene deposits of South America, and occasionally in the Pleistocene cave deposits of North America, as far north as Kentucky. The armored edentates, such as the armadillos and glyptodonts, are connected with the megatheriums through *Megalonyx*, which has ossified plates imbedded in its skin. These isolated plates became united into transverse rows in the armadillos and into a solid carapace in the glyptodonts. The gigantic glyptodon (q.v.) and the allied *Dædicurus*, from the Pleistocene beds of Argentina, have the body inclosed in a solid massive carapace made of polygonal bony plates that are firmly soldered together in the adult animals, but loosely joined in the young individuals. The tail also is covered by heavy plates. The total length of the skeleton varies from 12 to 20 feet. Armadillos with movable transverse rows of dermal plates are found fossil in the Tertiary deposits of Patagonia, and the earliest forms show no close points of relationship with the glyptodonts. The genera are *Chlamydotherrum*, *Dasyus*, *Eutatus*, and *Proeutatus*, of which the first mentioned attained the bulk of a rhinoceros. Compare GANODONTA.

Consult also the reports of the scientific expeditions sent by the American Museum of Natural History, New York, Princeton University, etc.

EDENTON. A town, formerly a port of entry, and the county seat of Chowan Co., N. C., 115 miles (direct) east by north of Raleigh, on Albemarle Sound, and on the Norfolk and Southern Railroad, and on the lines of two steamship companies (Map: North Carolina, F 1). It contains a United States fish hatchery,

and has extensive herring and shad fisheries, cotton mills, a peanut factory, and considerable lumber interests. The water works and electric-light plant are owned by the city. Founded in 1712, Edenton was originally known as Queen Anne's Creek and received its present name in honor of Charles Eden, an early Colonial governor. Here was held, on Oct. 24, 1774, the famous Edenton Tea Party, at which 52 women formally voted that they would not conform "to that Pernicious Custom of Drinking Tea" and "would not promote ye weare of any manufacture from England." Pop., 1910, 2789.

EDER, a'dër, JOSEPH MARIA (1855-). An Austrian chemist. He was born at Krems and was educated at the University and the Polytechnic Institute of Vienna. In 1882 he was appointed professor of chemistry at the State Industrial School in that city and afterward assisted in the organization of the Imperial Educational and Experimental Institute for Photography, of which he was appointed director in 1888. Especially noteworthy are his investigations on the influence of light of various wave-lengths upon silver salts, which resulted in the development of orthochromatic photography. He also invented a new photometric method (the now extensively used aristo papers (chlorogelatin papers)). His publications include: *Die Momentphotographie in ihrer Anwendung auf Kunst und Wissenschaft* (2d ed., 1886; 2d series, 1888); *Anleitung zur Herstellung von Momentphotographien* (2d ed., 1887); *Photographie mit Bromsilbergelatine* (4th ed., 1890); *Versuch über Photographie mittels der Röntgenschen Strahlen*, with Valenta (1896); *System der Sensitometrie photographischer Trockenplatten* (1899-1902); *Beiträge zur Photochemie und Spektralanalyse*, with Valenta (1903); *Atlas typierter Spektren* (1911). He was from 1887 to 1911 editor of the *Jahrbuch für Photographie und Reproduktionstechnik*.

EDERSHEIM, a'dërshim, ALFRED (1825-89). An English biblical scholar. He was born in Vienna, of Jewish extraction, and was educated at the university in that city. Unable to complete his university education because of financial obstacles, he accepted a tutorship in Pest, where he was converted to Christianity by John Duncan (q.v.). After studying theology in Edinburgh and Berlin, he was ordained to the Presbyterian ministry (1846) and soon afterward received an appointment to the Free church, Aberdeen, with which he remained associated for 12 years. He subsequently became select preacher to the University of Oxford (1884-85) and Grinfield lecturer on the Septuagint (1896-88, 1888-90). His principal work is entitled *The Life and Times of Jesus the Messiah* (1883), and he also published works entitled *Bible History* (of the Old Testament, 7 vols., 1876-87); *Jewish Social Life in the Days of Christ* (1876); *The Exodus and the Wanderings in the Wilderness* (1876).

EDESON, ROBERT (1868-). An American actor, born at New Orleans, La. He first appeared at the Park Theatre, New York City, in 1887, in *Fascination*. He starred in the following plays: *Soldiers of Fortune* (1902); *Ransom's Folly and Strongheart* (1905-07); *Classmates* (1907); *The Sinner* (1908); *The Call of the North* (1908, 1909); *The Offenders* (1908); *The Noble Spaniard* (1909); *The Outpost* (1909); *A Man's a Man* (1910); *The Cave Man* (1911); *The Indiscretion of Truth* (1912);

Fine Feathers (1913). He played the rôle of Ma-Wo-Cha-Sa in his own play, *Where the Trail Divides* (1910).

EDES'SA (Lat., from Gk. Ἔδεσσα, *Edessa*). The ancient capital of Macedonia, formerly known as *Æga*. It was situated 46 miles west of Thessalonica, at the head of a defile commanding the approaches from the seacoast to the interior. It was the original residence of the Macedonian kings and was the burial place of the royal family long after it ceased to be the seat of In Edessa Philip II was murdered by Pausanias, 336 B.C. Alexander the Great (q.v.) was buried at Alexandria, but Edessa remained the royal burial place, and when Pyrrhus occupied the place the royal tombs were plundered by his Gallic mercenaries. In Roman times Edessa was an important post on the great road from Pyrrhachium to Thessalonica. The modern city of Voden (q.v.) is built on the site of Edessa, and only scanty remains of the ancient buildings are preserved.

EDESSA (modern name, *Urfah*, or *Orfa*). A very ancient city on the river Daisan, in the north of Mesopotamia (in the modern Vilayet of Aleppo), 78 miles southwest of Diarbekir. Though the town is of very early origin, it is with the conquest of Persia by the Greeks that the history of Edessa first becomes clearer. Seleucus, in particular, is said to have done much for the aggrandizement of the city, and its prosperity increased under an independent line of kings reigning just before and just after the beginning of the Christian era. Christianity was introduced into Edessa at an early period, and the supposed relations of King Abgarus and Christ are embodied in the famous letter found in Edessa by Eusebius at the beginning of the fourth century. (See *ABGAR*.) In the reign of Trajan the place was made tributary to Rome and in 216 A.D. became a Roman military colony under the name of Colonia Marcia Edessenorum. Edessa, Nisibis, Damascus, and Antioch were the four greatest cities of Syria. During this period its importance in the history of the Christian Church continued to increase. More than 300 monasteries are said to have been included within its walls; it was the birthplace, or, at any rate for a time, the headquarters, of St. Ephraim Syrus. The church founded by Ephraim it became the principal center of Syrian learning and literature during the fourth, fifth, and sixth centuries and played an important part in the Arian and other controversies. Its famous university, or school of the Persians, was closed, on account of heretical tendencies, by the Emperor Zeno towards the end of the fifth century. With the extension of the religion of Islam in the seventh century Edessa fell into the hands of the Arabian caliphs. Christianity declined, and wars at home and abroad during the caliphate destroyed likewise the temporal splendor and pre-eminence of Edessa, till, in 1040, it fell into the possession of the Seljuk Turks. The Byzantine emperors succeeded in recovering Edessa, but the Viceroy contrived to make himself independent. He was, however, hard pressed by the Turks, and this rendered it easy for the Crusader Baldwin (q.v.), the brother of Godfrey of Bouillon, to gain possession of the city (1097 A.D.) and make it the capital of a Latin principality and the bulwark of the Kingdom of Jerusalem. Under the Frankish princes Edessa held out valiantly against the Mussulmans, till at length

EDFU
TEMPLE OF HORUS
THE GREAT COURT, AND THE ENTRANCE TO THE HYPOSTYLE HALL

Zengi, ruler of Mosul, succeeded in taking the town and citadel in the year 1144, when all the Christian churches were converted into mosques. An attempt made by the inhabitants to throw off the Mohammedan yoke completed the ruin of Edessa. Its inhabitants were defeated by Nur-ed-Din, and all who were not massacred were sold as slaves. After many vicissitudes, in the course of which Edessa fell successively into the hands of the sultans of Egypt, the Byzantines, the Mongols, Turkomans, and Persians, the city was finally conquered by the Turks in 1637, and has since formed a portion of the Turkish dominions. On its site stands the modern city of Orfa, or Urfah, with a population variously estimated at from 30,000 to 50,000, mostly Mohammedans. The modern city has numerous mosques and bazars, manufactures of cotton goods, goldsmiths' wares, and morocco leather, commerce in British manufactures obtained by way of Aleppo, and a large trade in grain, etc., with Syria. It is regarded by the Orientals as a sacred city, because they believe it to have been the residence of Abraham. In 1895, on October 28-29, there was a terrible massacre of Armenians by the Turks. A still worse massacre, involving, it is said, 8000 Armenians, followed on December 28-29 of the same year. (See ARMENIA, *History*.) Consult the article "Edessa in Osroene," by Meyer, in Pauly-Wissowa, *Real-Encyclopädie der klassischen Altertumswissenschaft*, vol. v (Stuttgart, 1905).

EDFU, ʾēd'fū (Coptic *Atbō*). A town of Upper Egypt, on the left bank of the Nile (lat. 25° 1' north, long. 32° 16' east), about 60 miles above Thebes. The chief local deity was Horus (q.v.), whom the Greeks identified with Apollo and for this reason called the place Appollinopolis. As *Apollinopolis Magna* it was distinguished from *Apollinopolis Parva* (the modern Qūs), the seat of worship of the god Haroëris (q.v.). Edfu was celebrated in Egyptian mythology as the scene of one of the great contests between Horus and Set. The legend is given in full in Wiedemann's *Religion of the Ancient Egyptians* (1897). The great temple of Horus at Edfu, which stands to-day almost intact, is in a better state of preservation than any other Egyptian temple. It was begun on the site of an older temple in 237 B.C., under the reign of Ptolemy III Euergetes II, and was completed and dedicated under Euergetes II about a century later. Considerable additions were made to it by later monarchs down to the year 57 B.C. Including the court, it is some 451 feet in length, and its façade is 250 feet wide. A gateway, 50 feet high, between two immense pylons, over 100 feet in height and covered with inscriptions, gives entrance to a splendid court (161 × 140 feet) inclosed by a double colonnade of 32 pillars, each of a different design. At the upper end of the court is the great portico, its roof supported by 18 pillars, and then comes a hypostyle hall of 12 pillars. This gives access to two successive vestibules leading to the sanctuary, which is surrounded by an open corridor. A number of chambers, ranged along the wall of the temple, open into this corridor. From the pylons extends the outer wall which incloses the court and all the temple buildings in a single great quadrangle. The principal buildings are richly decorated with sculptures and paintings and contain numerous inscriptions, chiefly of a religious or mythological character. Both the court and the temple were formerly nearly cov-

ered up with rubbish, and Arab hovels were built against the walls and even upon the roof; but early in the sixties Mariette, by permission of the Khedive, cleared away the débris and removed the wretched buildings which encroached upon the temple.

The so-called Birth House, built by Euergetes II and decorated by Soter II, stands near the entrance of the great temple of Horus. It is surrounded by a gallery whose roof is supported by pillars adorned with figures of the god Bes. Consult: Lepsius, *Briefe aus Aegypten, Aethiopien*, etc. (Berlin, 1852); Brugsch, *Reiseberichte aus Aegypten* (Leipzig, 1855); Mariette, *Monuments of Upper Egypt* (London, 1877); Breasted, *Ancient Records of Egypt*, vol. ii, passim (Chicago, 1907).

EDGAR, or **EADGAR**, ʾēd'gēr (944-975). A king of the English, called Edgar the Peaceful. He was a son of Edward, or Edmund the Magnificent. In 957, as the leader of a revolt, he became a ruler of Northumbria and Mercia, and on the death of his brother Edwy, or Eadwig, in 958 he was called to the throne by the entire people, succeeding to the Kingdom of the West Saxons in addition to that which he already controlled. During his reign of 17 years he had for his chief adviser the able Dunstan, Archbishop of Canterbury. He brought about the establishment of national consolidation, the reformation of the clergy, the improvement of the judiciary system, and the formation of a fleet to defend the coast against the Norsemen.

EDGAR. The son of the Earl of Gloster, in Shakespeare's *King Lear*, whose ill treatment, wanderings, feigned madness, and sweet forgiveness of his unjustly suspicious father form the secondary plot of the play.

EDGAR, SIR JAMES DAVID (1841-99). A Canadian legislator and author, born at Hatley, in the Province of Quebec. He was educated at Lenoxville and at the city of Quebec, and was called to the bar in 1864. He was a Liberal member of the House of Commons from 1872 to 1874 and was reelected in 1884, 1887, and 1891. In 1889 he was instrumental in securing the passage of the Canadian Copyright Act. In 1894 he introduced the question of international arbitration, in the House of Commons, supporting it by a notably able speech and procuring the passage of a resolution in its favor. On the advent to power of Sir Wilfrid Laurier in 1896, he was appointed Speaker of the Commons and in 1897 became a member of the Queen's Privy Council. In addition to his contributions to the daily press he published two volumes of poems: *This Canada of Ours and Other Poems* (1893) and *The White Stone Canoe* (1895). He also published *The Insolvent Act of 1864* (1865).

EDGAR ATHELING, or **EADGAR THE ATHELING** (c.1057-c.1120). An English prince, a grandson of Edmund Ironside. He was born probably in Hungary, whither his father had been exiled by Canute. After the death of Edward the Confessor, Edgar was the nearest heir to the crown, which passed, however, to Harold; after the death of Harold, Edgar was chosen King at London, but was soon compelled to submit to William the Conqueror. Edgar's life was a succession of fruitless struggles, his most noteworthy achievement being his expedition into Scotland (1097) for the purpose of reinstating his nephew Edgar as King of that country. In 1099 he engaged in the Crusade and returned to England during the reign of

Henry I. His last years were spent in obscurity, and the date of his death is not known. Consult Freeman, *History of the Norman Conquest*, vols. iii-v (Oxford, 1873), and *Reign of William Rufus* (2 vols., ib., 1882).

EDGARTOWN. A town, port of entry, and the county seat of Dukes Co., Mass., on the east shore of the island of Martha's Vineyard, 27 miles (direct) southeast of New Bedford (Map: Massachusetts, F 7). It has a small but well-sheltered harbor and was formerly a whaling port. At present it is known chiefly as a summer resort, although some fishing is carried on. Edgartown was founded in 1642 and was incorporated in 1671. It contains a Carnegie library. Pop., 1900, 1209; 1910, 1911. Consult Banks, *History of Martha's Vineyard* (Boston).

EDGEHILL. A hill ridge in Warwickshire, England, 7 miles northwest of Banbury. It gave its name to the first great battle of the Civil War, which was fought there on Sunday, Oct. 23, 1642, between the Royalist forces under Charles and the Parliamentarians under the Earl of Essex. The King's forces had the advantage in numbers and in cavalry as well as in position upon the hill; Essex, however, had the more formidable train of artillery. He began the fight by firing upon the Royalists, who immediately replied with their cannon. The Royalists descended the hill, and Prince Rupert, who led the right wing, charged with his cavalry the left wing of the Parliamentarians, broke it, and pursued it to Kineton, where his men, regardless of the main army, busied themselves in plunder. This was the fatal movement of the day. The right wing of the Parliamentarians had charged and recharged with the greatest success, until, after some stubborn fighting around the royal standard, the Royalists broke and retreated towards the hill. Disastrous to both armies, the result of the battle was indecisive. Over 4000 men were slain at the foot of Edgehill, and of these the greater number were Royalists.

EDGERTON. A city in Rock Co., Wis., 25 miles by rail southeast of Madison, on the Chicago, Milwaukee, and St. Paul Railroad (Map: Wisconsin, D 6). It contains a public library. Tobacco is the staple agricultural product, and nearly half the tobacco raised in the State is shipped from this place. The water works are owned by the city. Pop., 1900, 2192; 1910, 2513.

EDGEWATER. A borough in Bergen Co., N. J., opposite New York City, on the Hudson River, 6 miles north of Jersey City, and on the New York, Susquehanna, and Western and the Erie railroads (Map: New Jersey, E 2). The chief industrial establishments are large corn-product and sugar refineries, marble works, and chemical factories. Pop., 1900, 1006; 1910, 2655.

EDGEWOOD. A borough in Allegheny Co., Pa., 7 miles east of Pittsburgh, on the Pennsylvania Railroad. It is the seat of the Western Pennsylvania Institute for the Deaf and Dumb. Pop., 1900, 1139; 1910, 2596.

EDGEWORTH, MARIA (1767-1849). An Irish novelist of Irish and English life, who was born at Black Bourton, Oxfordshire, but whose home was at Edgeworthstown, Ireland. Her Irish stories were the first to make a careful study of provincial life and manners. As such, they represent a distinct step in the development of fiction in English and are the progeni-

tors of a countless family of similar productions, including Sir Walter Scott's novels of Scottish life. Sir Walter himself declares, in the preface to *Waverley*, that it was from her he took the idea of doing for Scotland what she had done for Ireland. Miss Edgeworth was also the first in English fiction to give careful and respectful attention to peasant life. Her work proved a potent influence in England, and one of the greatest of novelists, Turgenev (q.v.), confesses (consult Anne Thackeray Ritchie's account of Maria Edgeworth in *The Book of Sibyls*, London, 1883) that his studies of the Russian peasant were suggested by like work of Miss Edgeworth's. The best of her stories is *Castle Rackrent* (1800), which first introduced English readers to Irish life. It is a picture of the reckless, devil-may-care squirearchy of pre-Union days, and is recognized by good judges as a work of rare excellence in its kind. *Castle Rackrent* was followed by *Ennui* (1809), which is a study of an absentee landed proprietor; and after *Ennui* came *The Absentee* (1812), which presents a different aspect of absenteeism. In the fourth of her Irish novels, *Ormond* (1817), the life of the Catholic gentry of the old Celtic stock is the theme. The didactic strain, which came to her from her father, Richard Lovell Edgeworth (q.v.), is more or less of a blight upon her novels of English life, though certain of these are still highly entertaining and entitle her to a secure place among English novelists of the second rank. Of such are, notably, *Belinda* (1804), *Leonora* (1806), and *Helen* (1834). Her didacticism, pure and simple, found expression in her first considerable effort, *Practical Education* (1798), written in collaboration with her father, and it was pervasive in *The Parent's Assistant* and other books for children, which, but for this unfortunate infusion, might to-day be as popular as they were in their author's own generation. Consult, besides *The Book of Sibyls*, mentioned above: Emily Lawless, *Maria Edgeworth* (New York, 1904), inadequate, but a critical biography convenient in its brevity; A. J. C. Hare, *Life and Letters of Maria Edgeworth* (ib., 1895); W. D. Howells, *Heroines of Fiction* (ib., 1901), especially concerning the novels of English life; H. S. Krans, *Irish Life in Irish Fiction* (New York and London, 1903); Hill, *Maria Edgeworth and her Circle in the Days of Bonaparte and Bourbon* (New York, 1910).

EDGEWORTH, RICHARD LOVELL (1744-1817). An English author. He was born at Bath, was educated at Trinity College, Dublin, and Corpus Christi, Oxford, and began the study of law, but gave it up and settled upon the family estates at Edgeworthstown, County Longford, Ireland. He was a close friendship for Dr. Erasmus Darwin, and was a love for science, and much of his writing was upon scientific subjects. To his closest friend, Thomas Day, he is said to have suggested the writing of *Sandford and Merton*. He was a member of the last Irish Parliament, and, disregarding personal considerations, voted against the proposition of a union with England. In 1785 he was one of the founders of the Royal Irish Academy and during the following two years devoted most of his time to mechanics and agriculture. Among his works are: *Letter to Lord Charlemont on the Tellograph and on the Inevitable of Ireland* (1797); *Practical Education* (1798); *Poetry Explained for Young People* (1802); *Professional*

Education (1808); *Readings in Poetry* (1816); *Essay on Construction of Roads and Railways* (1817). Consult *Memoirs* by himself and his (London, 1820; 1844).

EDGEWORTH DE FIRMONT, HENRY ESSEX (1745-1807). An Irish clergyman, confessor to Louis XVI of France. He was born at Edgeworthstown (County Longford), was educated by the Jesuits at Toulouse, France, was trained for the Roman Catholic priesthood in Paris, and upon his ordination assumed the additional name of De Firmont. Having worked among the Irish and English in Paris, he was in 1791 appointed confessor to the Princess Elizabeth, sister of Louis XVI, and was recommended by her to the King. After the condemnation of the King by the Convention on Jan. 20, 1793, he was summoned to the Temple, through Garat, Minister of Justice. Between 5 and 6 o'clock on the morning of the execution (January 21) he celebrated the mass, and later he rode with the King to the scaffold. He escaped to England, which he reached in 1796, and where he was offered by Pitt a pension, which he then declined, but in 1806 accepted. He followed Louis XVIII to Blankenburg and later to Mittau, where he died of a fever contracted while among French prisoners. His epitaph was written by Louis XVIII.

EDGREN, ANNE CHARLOTTE LEFFLER (1849-92). A Swedish realistic novelist and dramatist, born in Stockholm, writing under the name of Leffler. She was twice married, first to Municipal Secretary G. Edgren (1872-89), then (1890-92) to the Italian Duke of Cajanello. Her short stories, collected under the titles *By Chance* (1869), *From Life* (1882-83), *A Summer Story* (1886), *Woman and Love* (1890), and her dramas, *The Actress* (1873), *The Curate* (1876), *The Fairy* (1880), *Ideal Women* (1883), *The Struggle for Happiness* (1887), and, most popular of all, *A Rescuing Angel*, are the most noteworthy and characteristic of her many works. There is a *Life of Edgren* by Ellen Key (1893).

EDHEM PASHA, *ed'hëm pâ-shâ'* (c.1813-93). A Turkish soldier and statesman, born of Greek parents on the island of Chios. In 1831 he was taken to Paris, where he was educated in engineering and made a special study of mining. Returning to Turkey in 1839, he was made a captain in the army and was assigned to duty in the topographical corps. He became an aid on the staff of the Sultan Abdul-Medjid in 1849, and rose rapidly to the position of general of a division and chief of the Sultan's military household. In 1854 he began his diplomatic career in a special mission to Servia. In 1856, incurring the displeasure of the Sultan, he was removed from his official position, but shortly afterward was restored to power, made a member of the Council of the Tanzimat (the old theoretical constitution), and appointed Minister of Foreign Affairs. Under Abdul Aziz he held various positions of importance. In 1876 he was Ambassador at Berlin, and one of the representatives of the Porte at the international conference in Constantinople. Early in 1877 he was made Grand Vizier. From 1879 to 1883 he was Ambassador at Vienna.

EDHEM PASHA (1851-1909). A Turkish soldier. By 1877 he had become a colonel, and during the siege of Plevna was acting brigade commander. His bravery attracted the attention of the Porte, and his rise was rapid. He was

appointed Governor-General of the Vilayet of Kossovo, adjutant general, and field marshal, and in 1897 received the chief command of the Ottoman army in the Græco-Turkish War. He mobilized 55,000 troops in three weeks, defeated the Greeks at the Maluna Pass, marched into Thessaly, and entered Larissa. His direction of the army, both in the field and in its hospital and sanitary arrangements, was very skillful. See GREECE.

EDICT' (Lat. *edictum*, from *edicere*, to proclaim, from *e*, out + *dicere*, to say). A rule of law promulgated by a superior magistrate. The power of making edicts (*ius edicendi*) belonged generally to the higher magistrates at Rome; but it was by the curule ædiles, and more extensively still by the two prætors—the *prætor urbanus* and the *prætor peregrinus*—that it was prominently exercised. As this power was co-extensive with the possession of what were called the honors (*honores*), it was frequently spoken of as the *ius honorarium*; and from its being exercised chiefly by the prætors, it was also known as the *ius prætorium*. The edicts of the prætors are mentioned by Gaius among the sources of the Roman law: but, strictly speaking, they are to be considered as rules promulgated by the "prætor" ring upon their office rather than as expressions of the will of the Roman people. The edict of one prætor was not binding on his successor, but, as edicts promulgated by one prætor were usually adopted and confirmed by his successors in office, they thus came gradually to acquire the character of law. Edicts which thus became a part of the permanent law of the Republic were frequently known by the names of their first promulgators, though they were often named with reference to the formula and the *actio* which they established.

The power of promulgating edicts is supposed to have been derived from the kings to the consuls, and through them to the prætors, and thus to have formed part of what we should call the royal prerogative. Even in Cicero's time the study of the edict had become a regular branch of the study of the law. In 67 B.C. the Lex Cornelia provided against the abuse of passing edicts for the decision of particular cases, by requiring the prætors to decide in conformity with the edicts which they promulgated upon assuming office, which were known as permanent edicts (*edicta perpetua*). The object of the edict, according to the Roman jurists, was to aid, supplement, and correct the civil law, and to render it more conducive to the public service, and they speak of it as "the living voice of the civil law." It was, in short, an indirect form of legislation, which public opinion sanctioned for the public convenience, and there can be no doubt that, like the principles of equity promulgated by the chancellors in England, it contributed what was ultimately the most valuable part of the Roman law.

The edicts of the emperors, like those of the prætors, were also general rules, promulgated directly; but these had the superior validity which attached to the supreme magistracy and immediately took on the character of permanent law. They formed an important element in the *constitutiones*, in which the Imperial contribu-

tions to the law of the Empire were summed up. There were many commentators on the edicts under the emperors, among whom Labeo is mentioned and cited by Ulpian (*Dig.* 4, tit. 3, sec. 9). Julian is supposed to have collected and arranged the edicts and given to them a systematic form. Gaius, Ulpian, and Paulus composed treatises on the edicts of the curule ediles; and it is chiefly from the writings of these and the other jurists excerpted in the *Digest* that we know anything of the character of the edict, the portions of it which have been preserved being *Fragmenta Edicti Perpetui* (Frankfort, 1733). See CIVIL LAW; CONSTITUTION; DIGEST; PANDECTS.

EDICT OF NANTES, nãnt. See NANTES, EDICT OF.

EDILES. See **ÆDILES**.

EDI'NA. A city and the county seat of Knox Co., Mo., 47 miles west by north of Quincy, Ill., on the Quincy, Omaha, and Kansas City Railroad (Map: Missouri, D 1). It has flouring and saw mills, a carriage and wagon factory, a nursery, a creamery, a cold-storage plant, etc. There is considerable trade in live stock and agricultural produce. Pop., 1890, 1456; 1900, 1605; 1910, 1562.

EDINBURGH, ăd'n-bür-ū. A city and a royal and parliamentary burgh, the capital of Scotland and the county town of Edinburghshire, situated on a series of eminences about 2 miles south of the Firth of Forth and 47 miles east of Glasgow, in lat. 55° 57' N. and long. 3° 12' W. (Map: Scotland, E 4). It now includes the town of Portobello on the Firth of Forth, as well as various other outlying districts which were annexed in 1896 and subsequently. The mean altitude is about 200 feet above the sea level. Edinburgh is divided into the Old Town and New Town by a deep ravine, the former bed of the Nor' Loch, which has been turned into the charming recreation grounds of East and West Princes Street Gardens. The gardens are crossed by the North Bridge, the Waverley Bridge, and the Mound, an artificial embankment, on which are built the Royal Scottish Academy of Painting, Sculpture, and Architecture (founded 1826) and the National Gallery (founded 1850). The Academy, in the Doric style, was formerly the meeting place of the Royal Society (founded 1783) and the Society of Antiquaries of Scotland (founded 1780); it was the Royal Institution, the name being changed in 1910. The National Gallery contains a very complete collection of the Scottish school of painting as well as numerous examples of the old masters. The National Portrait Gallery and the Antiquarian Museum are housed in Queen Street. The Old Town, extending from the Castle on the west to Holyrood Palace on the east, contains the nucleus of the ancient burgh of Edinburgh, which grew up about the Castle, and the neighboring burgh of Canongate, which had its origin in the foundation of the abbey of Holyrood, and which retained its separate municipality until the extensions of 1856, when it became an integral part of Edinburgh. Two main streets running almost parallel intersect the Old Town: High Street—which is known throughout its length by five different names, viz., Castle Hill, Lawnmarket, High Street, Netherbow, and Canongate—and Cowgate.

The Castle occupies a rocky eminence 300

feet above the valley and is accessible only on its eastern side. The present edifice dates from the fourteenth century. It has frequently served as both a place of residence and a prison for the Scottish kings. It was here that Mary, Queen of Scots, gave birth to her son James. In the so-called crown room are kept the crown regalia, known as the *Honours of Scotland*. Holyrood Palace was the favorite residence of the Scottish monarchs and was the scene of some of the tragic events in the life of Mary, Queen of Scots. Among the other notable features of the Old Town are the parish church of St. Giles, the present edifice dating from the fourteenth century, restored 1879-83, with a handsome lantern spire, the burial place of the Marquis of Montrose and the scene of the signing of the Solemn League and Covenant; the old Tron Church, the house occupied for a number of years by the great reformer, John Knox; Parliament House (1632-40) which was the meeting place of the Scottish Parliament, but utilized since the Union as the seat of the supreme courts and containing the Advocates' Library, with about 550,000 volumes, the largest in Scotland and one of the five in the United Kingdom entitled to a copy of every book published in the kingdom. It also contains the Signet Library (over 110,000 volumes). The churchyard of Canonsgate Church is the burial place of Dugald Stewart, Robert Fergusson, and Adam Smith, and Greyfriars' Churchyard contains the tombs of George Buchanan, Allan Ramsay, and Robertson the historian.

The chief thoroughfare of the New Town is Princes Street, which skirts the ravine separating the two towns and commands for its entire length an excellent view of the picturesque Old Town. In the eastern gardens facing Princes Street stands the Scott Monument, and at the easterly end of the street stand the Post Office and Register House, the latter being the repository for all title deeds and public records. Above these buildings rises the Calton Hill to a height of about 355 feet above the sea level, crowned by the Royal Observatory, Nelson Monument, and National Monument. It commands a magnificent panorama, excelled only by that obtained from Arthur's Seat, which rises to a height of 822 feet behind Holyrood. At the foot of Calton is the old Calton burial ground, which contains the grave of David Hume the philosopher and historian. In the New Town is St. Mary's Cathedral (Scottish Episcopal), in early Pointed style, with a 275-foot spire; it was opened for worship in 1879.

Edinburgh is governed by a city council, which elects from its own members a lord provost, a city treasurer, and seven bailies, who constitute the civil magistracy. The city sends four representatives to Parliament. In the matter of municipal undertakings Edinburgh has been most active. Its water and gas supplies are managed by a joint commission with Leith. Since 1895 it has successfully operated an electric-light plant at a substantial annual profit. It also owns its street-railway lines, which, however, are operated by a private company at a rental of about 7 per cent of the capital outlay. Baths, a public laundry, ceme-teries, markets, and slaughterhouses are maintained by the corporation, and a considerable sum is expended annually in aid of technical education and for the maintenance of public

libraries. Following the lead of its sister city, Glasgow, Edinburgh has undertaken numerous schemes for the better housing of its working classes and has erected dwelling houses, which are let in flats at an exceedingly low rental. The city's system of sewerage has been much improved and has four separate outlets into the sea. Its 'disposed of in destructors or sold for purposes.

Edinburgh has long borne an enviable reputation as an educational centre. At the head of its institutions of learning stands the University (q.v.). Other prominent institutions are the Heriot-Watt College; Heriot's Hospital, founded by a bequest of George Heriot, the jeweler of James VI; Donaldson's Hospital, Gillespie's Hospital, the Merchant Company's Schools, the high school, and Fettes College, the last named being modeled on the plan of Rugby and Eton. The Royal Infirmary, consisting of a series of detached buildings in the Scottish baronial style, is considered one of the most excellently equipped institutions of its kind in Europe. There are numerous parks and recreation grounds, including Queen's Park of nearly 700 acres, the Meadows, the Links, and Braid Hills.

Edinburgh is an important manufacturing town, and derives considerable commercial importance from its various banks and insurance offices. The industries are brewing (two-thirds of the ale or beer brewed in Scotland being made in or near Edinburgh), printing and publishing with the kindred arts, distilling, iron founding, tanning, and coach building, manufacture of articles in India rubber, of house furniture, and of jewelry, and the rearing of young trees in nurseries in and around the town. Imports and exports amounted in 1905 to \$85,442,000 and \$37,110,000 respectively.

Edinburgh is the place of residence of considerable numbers of the Scottish landed gentry, and its society is regarded as unusually polished from the predominance of the professional and literary elements in its composition. This arises from its status as a university town and from the presence of the supreme law courts of Scotland. The picturesque and commanding situation of the city, combined with its literary fame, has acquired for it the name of the "Modern Athens." The climate is healthful, the mean temperature averaging 48° F., with an average rainfall of about 27 inches. Pop., 1801, 66,544; 1851, 160,352; 1901, 317,459 (area of the city, 10,094 acres); 1911, 320,318 (area, 10,877 acres).

Edinburgh is supposed to have sprung up round the castle built in the seventh century by Edwin, King of Northumbria (Cadwine's burgh). It quickly grew to be a place of importance and in the eleventh century was a royal residence. Around the abbey of Holyrood (q.v.), which David I founded in 1128, rose the town of Canongate, later annexed to old Edinburgh. From Robert the Bruce the burghers received a charter which granted them a great degree of self-government and the possession of the port of Leith. In the fifteenth century the Scottish kings sought refuge from their turbulent nobles in the castle of Edinburgh. After 1436 the town became the capital of the kingdom and the usual meeting place of Scottish parliaments. The Old Town, which was walled about 1450, was of very narrow limits. Under James II and James III numerous privileges and im-

munities were granted, notably the charter of 1452 and the Golden Charter of 1482. The city was closely connected with the chief events of Scottish history for the next 250 years, witnessing the fortunes of Mary Stuart (q.v.), the spread of the Reformation, and the battles of the Covenanters. After the Reformation the city became the seat of the youngest of the Scottish universities. The accession of James VI to the English throne in 1603, and the union with England in 1707, deprived Edinburgh of much of its political prominence, but it acquired instead great fame as the literary centre of Scotland, the home of Walter Scott, Jeffrey, and John Wilson ("Christopher North"). The New Town, planned by James Craig, dates from 1763, after the Nor' Loch had been drained and bridged. In 1843 Edinburgh, as the religious centre of Scotland, was the scene of the famous secession from the Established church which ended in the formation of the Free church of Scotland. The coronation ceremonies of King George V, in July, 1911, at Holyrood recognized afresh Edinburgh's position as capital of Scotland.

EDINBURGH, ALFRED ERNEST ALBERT, DUKE OF (1844-1900). The fourth child and second son of Queen Victoria. He was Earl of Ulster and of Kent and in 1893 succeeded his uncle as Duke of Saxe-Coburg and Gotha. He was educated by special tutors, went into the royal navy at the age of 14, and served chiefly on foreign stations. The crown of Greece was offered to him in 1862 by 230,000 out of 241,000 votes cast; but an agreement of Great Britain, Russia, and France, that the throne should not go to a noble of any one of these powers, prevented his acceptance. He married at St. Petersburg, on Jan. 23, 1874, Marie Alexandrovna, Grand Duchess of Russia. He was a good naval officer and became admiral of the fleet in 1893. He was an amateur in music and a collector of glass and pottery.

EDINBURGH, UNIVERSITY OF. A Scottish university which owes its origin to a bequest of Robert Reid, first Bishop of Orkney in 1588, and to the later encouragement of the municipality of Edinburgh. In 1563 the latter purchased ground on the site of "Kirk o' Field," and by grants of confiscated church property from Queen Mary, and a charter from James VI (James I of England) in 1582, the university was finally established. It was formally opened, and teaching begun, in 1583, though it was at

first, strictly speaking, only a college of arts. In 1642 a chair of theology was established and in 1685 one of medicine. After 1688 the institution, with other Scottish universities, was subjected to parliamentary visitation. At the beginning of the eighteenth century the present arrangement of the faculty of arts came into existence, and this, with the reorganization of the institution, including the establishment of a law faculty, gave it the rank and title of the University of Edinburgh, which it has since held. Until 1861 the university had been almost entirely under the control of the municipality, but in that year, by the Act of Parliament regulating Scottish universities, the administration was vested in a self-governing corporation of members, the *senatus academicus*, and the university court, together with a body of curators selected partly by the university and partly by the city, in whose hands lay the patronage of the professional chairs. By the Universities of Scotland Act of 1899, the University Court was constituted as a body corporate, holding all property and having all powers of administration. It consists of the rector, principal, Lord Provost of Edinburgh, one assessor nominated by the chancellor, one by the rector, one by the Lord Provost, magistrates, and town council of Edinburgh, four by the general council, representatives of the affiliated colleges. The university senate, consisting of the principal and professors, regulates teaching and discipline. The general council, consisting of the chancellor, members of the court, professors, and graduates, reviews the measures presented to it, makes recommendations, elects the chancellor, and, with the general council of the University of St. Andrews, returns one member to Parliament. The chancellor confers degrees, sanctions changes in ordinances, and presides over the general council. The principal, elected by the curators for life, presides over the senate. The rector, an interesting mediæval survival found in Scottish universities, is elected by the students for three years and presides over the court. The office is almost invariably filled by some man, not necessarily connected with the university, who is distinguished in politics or letters, as Gladstone, Carlyle, Lord Rosebery, and Viscount Goschen. There are faculties of arts, science, divinity, law, medicine, and music. A students' representative council has certain rights of petition in matters affecting teaching and discipline.

Candidates for the M.A. degree traditionally must attend full courses in at least seven subjects: four—Latin or Greek, English or a modern language, or history, logic and metaphysics, or moral philosophy, and mathematics or natural philosophy—being required and three elective. Each course must consist of not fewer than 100 hours, or meetings of the class. For a degree with honors, special classes and courses are provided. Special regulations are in force for the higher degrees of D.Sc., D.Phil., and D.Litt., to all which women are admitted. The university grants also degrees in medicine, law, divinity, and music, of which those in medicine are open to women. There are a large number of bursaries (82) and many prizes, apportioned among the different faculties. The increase in the number of students and teaching force of the university led to a movement in 1869 for the enlargement of the buildings, and in 1878, sufficient sum having been raised, the "new

buildings" were erected. These, completed in 1888, together with the Old Hall, finished in 1897, and the School of Music (1858), constitute the modern additions to the original buildings. The university library, which contains 270,000 volumes and 8000 manuscripts, was founded by Clement Little in 1580. There are, besides, a number of special libraries in theology, classics, philosophy, history, physiology, and music. The museums include that of natural history (1812) and a considerable number in various departments of learning, partly or wholly belonging to the professors in the several subjects. The Royal Botanic Garden has also some connection with the university. The number of students in 1912-13 was 3352. In common with other Scottish universities the University of Edinburgh has been benefited by the grants of the Carnegie Trust. Long is the list of worthies: Blair, Akenside, Thomson, Hume, Goldsmith, the geologist Hutton, James Watt, Scott, Palmerston, Carlyle, Earl of Dalhousie, Stewart, Darwin, Robertson of Brighton, Robert Louis Stevenson, Crockett, Sir James M. Barrie, and Sir Conan Doyle. Its professors have been distinguished: Dugald Stewart, Sir William Hamilton, Playfair, Chalmers, John Wilson, Aytoun, Masson, and his successor, Saintsbury. Consult: Grant, *Story of the University of Edinburgh* (Edinburgh, 1888, best account); Dalziel, *History of the University of Edinburgh* (ib., 1862); J. Kerr, *Scottish Education, School and University from Early Times to 1908* (Cambridge, 1908); *University Calendar*.

EDINBURGH REVIEW. The first of the great critical periodicals which form a distinguishing feature of the literature of the nineteenth century. It was started in October, 1802, by a group of young men living in Edinburgh, the principal of whom were Francis Jeffrey (q.v.), Sydney Smith (q.v.), Francis Horner, and Henry Brunsdon (q.v.). So much was secrecy felt or it was found to be necessary to the success of the undertaking that, according to the account which Jeffrey gave to Robert Chambers in 1846, "the dark divans" of the reviewers were held for some time "in a dingy room off Willison's printing office in Craig's Close," to which each repaired alone, and "by back approaches or different lanes." Of the first number, 750 copies were printed; the demand exceeded this limited supply; 750 more were thrown off, and successive editions followed. In 1808 the circulation rose to about 9000 and in 1813 to about 13,000. The original publisher was the well-known Constable. Sydney Smith edited the first three numbers and was then succeeded by Jeffrey. The influence of the *Edinburgh Review* in developing and strengthening the political convictions of the Whig party cannot be overestimated; but its power was even more visible, certainly more immediately palpable, in its nature. The keenness of criticism, the abundance of wit, and the brilliancy of style which the writers created a sensation in the world of letters; and although in the case of Wordsworth, Southey, and other writers of the Romantic school, unfairness of a flagrant kind was undoubtedly exhibited and persevered in, yet rough justice was, on the whole, administered. After the period of Jeffrey the most brilliant contributor to the *Edinburgh Review* was Macaulay. It is now published in London. Consult Napier, *Life and Correspondence* (London, 1862).

EDINBURGSHIRE, **EDINBURGH**, or **MID-LOTHIAN**. A county in southeastern Scotland, lying on the south side of the Firth of Forth (Map: Scotland, E 4). Area, 386 square miles, while the county has but 1.2 per cent of the total area of Scotland, it has 10.7 per cent of the population. From the southern border, the Pentland Hills (mean height, 1000 feet, and highest point, Scald Law, 1898 feet) and the Moorfoot Hills (mean height, 800 feet, and the highest point, Blackhope Scar, on the Peebles-shire boundary, 2136 feet) run northeast through the country. In the north are fertile plains, varied by gentle slopes. The principal streams, none of which is large, are the Esk, Water of Leith, Almond, and Gala Water. The coast has coal-mining and other industries, but the county is chiefly agricultural, with large farms. Near Edinburgh are extensive nurseries, vegetable and fruit gardens, and dairy pastures. The leading manufacturing industry is paper making. Exclusive of Edinburgh and Leith, the county forms a parliamentary constituency. In 1801 population of Edinburghshire was 122,597; in 1851, 259,435; in 1871, 328,379; in 1891, 434,159; in 1901, 488,796; in 1911, 507,666. The principal burghs are Edinburgh, the county town and capital of Scotland, with 320,318 inhabitants in 1911; Leith, its seaport, 80,488; and Musselburgh, 15,938.

EDISON, **THOMAS ALVA** (1847-). A celebrated American electrician and inventor. He was born at Milan, Ohio, Feb. 11, 1847, and when he was seven years of age his family moved to Port Huron, Mich., where the remainder of his boyhood was passed. While a mere lad, he started in business as a newsboy on the Grand Trunk Railway. His spare hours were spent in reading and in boyish experiments, largely with printing presses and electrical and mechanical apparatus. In 1862 he published a weekly, known as the *Grand Trunk Herald*, and did the printing in a freight car that also served as a laboratory where he could carry on further experiments. For saving the child of a station master from the wheels of an approaching car, he was received as a pupil at the telegraph office at Mount Clemens and there learned to become an operator. While a brilliant and rapid operator, he was besides fun-loving and erratic, as well as too fond of experimenting and disregarding the rules of the office to remain long in any one situation. It was while thus engaged that he made his first important invention, a repeating instrument, which enabled a message to be transmitted automatically on a second line without the presence of an operator. From the West Edison went to Boston, where, owing to his skill as a rapid operator, he soon secured a position and was also able to work on various mechanical inventions which suggested themselves to his ingenious mind. Among these was a vote recorder, which, while accomplishing its object, did not possess merits of a sufficiently practical character to warrant its adoption. Recalling this failure, Mr. Edison said that afterward he investigated minutely the necessity of any particular invention before he attempted to reduce it to practice. In this has been his great success as an inventor. Few, if any, great scientific discoveries are to be credited to Edison, but he has triumphed over almost insurmountable difficulties, and by his skill and ingenuity brought to practical use and the advancement

of civilization what had often been suggested by some scientific investigator unable to bring it to a successful outcome or practical realization. While in Boston, Edison devised and partly completed a stock-quotation printer and later became connected with the Gold and Stock Telegraph Company of New York, whose apparatus and service he greatly improved. Valuable inventions of stock printing and other telegraph appliances were sold for \$40,000, which enabled Edison to establish a laboratory on his own account and to work out some of his more important ideas. About this time came his automatic telegraph system, by means of which increased speed and range of action were obtained. Edison's crowning achievement in telegraphy (see TELEGRAPH) was his invention of the quadruplex system, which followed a duplex system he had previously devised, and which was a great commercial success and made possible a far greater use of existing telegraph lines. Of the greatest value in the development of the telephone (q.v.), then recently invented by Bell, were the microphone and the carbon transmitter, and the latter of these devices was employed extensively in the earlier instruments. In 1878 Edison brought out his phonograph with the tin-foil cylinder, and about this time the megaphone. The most used of all Edison's inventions, and the one that required the most careful research and the most perfecting, was the incandescent light, which, brought out in 1879, was publicly exhibited in 1880. This new light soon achieved a remarkable success, and the inventor was fully occupied in improving the lamps themselves and the dynamos for generating the current. Mr. Edison also worked on the question of electric traction, but his achievements here, while attended with some success, were not so remarkable as in other fields. In 1886 his laboratory at Orange was built and furnished a commodious workshop for his later experiments. Here the kinetograph was developed, and the instrument in its well-known form of the kinetoscope was made a commercial success. Among his commercial ventures were the magnetic treatment of iron ore and a plant for the manufacture of Portland cement. The most notable of his later inventions is the nickel-iron storage cell, the product of many thousands of experiments in which Edison struck out boldly from all existing knowledge and precedent. This type of battery is extremely rugged, is practically incapable of electrical injury, and has a very high capacity per unit of weight. Its great field of service is the propulsion of vehicles and railway cars. He also brought out a disk phonograph with a diamond-point reproducer and other excellent features, and by synchronizing his phonograph and kinetoscope he produced (1913) realistic talking motion pictures. Edison received numerous honors at international expositions and from foreign governments, among which are his appointment as Chevalier of the Legion of Honor from France in 1878 and as Commander in 1889. In 1892 he received the Albert medal of the Society of Arts of Great Britain. Edison as an inventor stands unique among those men of the nineteenth century who applied scientific discoveries to the ordinary uses of man. His boldness in overcoming experimental difficulties, and his successful achievement of what might be termed all but impos-

sible, secured for him the name of Wizard. In considering his life and work, however, the distinction must be made between the pure scientist with mathematical and philosophical knowledge, and the ingenious inventor who can apply a scientific truth to a practical end. Of this latter class Edison stands at the head. For a life of Edison, consult Jones, *Thomas Alva Edison* (New York, 1908), and Dyer and Martin, *Edison: His Life and Inventions* (2 vols., ib., 1910).

EDISTO ISLAND. One of the "sea islands" so famous for long-staple cotton, on the South Carolina coast, about 25 miles southwest of Charleston (Map: South Carolina, D 4). It is formed by the branching of the Edisto River (q.v.) near the coast. The soil is fertile, and the vegetable trade of the island with the North is considerable. Pop., 1910, 3234.

EDISTO RIVER. A river in the southern part of South Carolina, formed about 6 miles west of Branchville, Orangeburg County, by the union of its north and south forks (Map: South Carolina, D 3). It flows southeast, then south, and divides into the North and South Edisto about 15 miles from the coast. These arms embrace Edisto Island and reach the Atlantic about 25 miles southwest of Charleston harbor and just north of St. Helena Sound. From the forks to its mouth the river is about 150 miles long, and it is navigable for light-draft boats throughout its length.

EDITIO PRINCIPIS, ē-dish'1-s prīn'sēps. The Latin term for the first edition of a book. The term is used especially with reference to the first printed edition of a Greek or Latin author. See INCUNABULA.

EDLUND, ēd'lund, ERIK (1819-88). A Swedish physicist. He was born in the District of Nerike and was educated at Upsala. In 1850 he became professor of physics at the Royal Academy of Sciences in Stockholm and in 1858 was instrumental in securing the introduction of meteorological stations in Sweden. He conducted these observatories until 1873, when a central meteorological station was erected. His scientific researches were confined chiefly to the theory of electricity. His publications include *Théorie des phénomènes électriques* (1874), in which he discusses unipolar induction, tracing the origin of electricity to the rotation of the earth and of the higher strata of the atmosphere. The meteorological observations made by Edlund from 1858 to 1873 were published in 14 vols. by the Academy of Sciences of Stockholm.

EDMONDSON, THOMAS WILLIAM (1869-). An American mathematician, born at Skipton-in-Craven, Yorkshire, England. After graduating from the University of London he studied at Cambridge and also at Clark University, Worcester, Mass. He was assistant professor of physics and associate professor of mathematics at New York University between 1896 and 1905 and thereafter professor of mathematics. His publications include: *Worked Examples in Coördinate Geometry* (1891); *Mensuration and Spherical Geometry* (1893), with W. Briggs; *Deductions in Euclid* (1901), and other mathematical textbooks. He was a contributor on astronomy to the second edition of the *NEW INTERNATIONAL ENCYCLOPÆDIA*.

EDMONTON, ēd'mon-ton. A city and the capital of the Province of Alberta, Canada, 192 miles north by northeast of Calgary (Map: Al-

berta, G 5), on the Canadian Pacific, the Grand Trunk Pacific, and the Canadian Northern railroads, and on the north branch of the Saskatchewan River. The city is laid out in wide, regular streets. The principal edifices are

the principal buildings, the University of Alberta, the high school and public school buildings, Alberta College, Robertson College, and a Roman Catholic convent and seminary. The manufacturing and industrial establishments include meat-packing plants, brickyards, saw mills, flour mills, elevators, foundries, machine shops, box and casket works, and manufactories of woodwork, aerated water, cigars, shoeboxes, clothing, beer, and bottles. Coal mining and lumbering have reached great proportions, and there are 30 coal mines in or near the city. Abundant supplies of timber and stone are found in the surrounding district. In 1910 the value of the manufactured products amounted to \$4,493,304, as compared with \$243,778 in 1900. The city owns and operates its electric-light and power, water, telephone, and street-railway systems. Natural gas exists in the vicinity, and oil is indicated in the territory tributary to it. Alluvial gold is found in the vicinity. The city is in a fertile agricultural district and is an important fur-trading station, being an old Hudson's Bay Company post. Edmonton has a meteorological station in daily communication with the United States Weather Bureau and is statistically the storm centre of the northern part of America. Pop., 1901, 2626; 1911, 24,900.

EDMONTON. An urban district of Middlesex, England, about 7 miles north of London in the Lea valley. Many artisans of the region have their homes here. Charles and Mary Lamb are buried in the churchyard, and the Bell Inn was made famous in Cowper's humorous poem of "John Gilpin." Pop., 1901, 46,899; 1911, 64,820. Consult Robinson, *The History and Antiquities of Edmonton* (London, 1819).

EDMUND, or **EADMUND** (AS., defender of property) (c.922-46). King of the English from 940 to 946. He was the son of Edward the Elder and the grandson of Alfred the Great and succeeded his half brother, Æthelstan, on the throne. Three years before his accession he had shown remarkable bravery in the battle with the Danes at Brunanburh. Soon after he became King a revolt broke out in the north, and Olaf, or Anlaf, the leader of the Danes from Ireland, was made King. For a time the revolt was successful, and the Danelaw (q.v.) was revived under a second Olaf and Ragnar; but about 944 Edmund subdued both kings. In 945 he conquered Cumbria and gave it to Malcolm of Scotland to be held in military service. Edmund was slain by an outlaw, May 26, 946, while at a banquet. Consult: Green, *Conquest of England* (London and New York, 1883); Hodgkin, *History of England, to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EDMUND, or **EADMUND** (c.981-1016). A king of the English, known as IRONSIDE. He was the son of Æthelred II, and half brother of Edward the Confessor. He is celebrated chiefly as the great opponent to Canute and the Danish party during the latter part of his father's reign. On the death of Æthelred, in 1016, the Danes proclaimed Canute King of England, but the citizens of London declared for Edmund,

who drew together his forces and engaged Canute at Pen. in Somersetshire, and at Sherston, in Wiltshire. In both battles he was victorious; but a severe defeat which he sustained at Assandun in Essex compelled him to make terms with the enemy. An entered into by which Engl. between the two kings—Canute obtaining possession of the north, and the south falling to the share of Edmund. It seems probable that it was also agreed that on the death of either the survivor was to succeed him. Edmund died a few weeks after this agreement had been concluded, and Canute became King of England, Nov. 30, 1016. According to the *Anglo-Saxon Chronicle*, Edmund received the surname of Ironside for his extraordinary courage and physical strength. Consult: Freeman, *The Norman Conquest*, vol. i (Oxford, 1873); Green, *The Conquest of England* (London and New York, 1883); Hodgkin, *History of England, to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EDMUND. The bastard son of the Earl of Gloster, in Shakespeare's *King Lear*.

EDMUND, SAINT (c.1170-1240). An English archbishop and ascetic. His name was Edmund Rich. He was born at Abingdon between 1170 and 1175. He early adopted the ascetic life and followed its rules with a rigor amounting to heroism. He studied at Oxford and Paris and became a priest. In 1227 he was one of the preachers of the Sixth Crusade. In 1234 he became Archbishop of Canterbury. He was involved in many disputes and quarrels, both political and ecclesiastical. In 1240, broken down by such contentions and his severe mode of life, he left his post and went to Pontigny, in France, soon after to Soisy, where he died Nov. 16, 1240. For his life, consult: Masse (Eng. trans., London, 1874); Wallace, (ib., 1893); Ward (ib., 1903).

EDMUNDS, ALBERT JOSEPH (1857-). An American librarian and Buddhist scholar, born at Tottenham, Middlesex, England. He entered the University of London in 1877, served as a secretary, spent 1884 in cataloguing the Sunderland (England) library, and then came to the United States. In 1887-89 he was assistant librarian of Haverford College, in 1889-90 he classified the Philadelphia library, and in 1891 became cataloguer of the Historical Society of Pennsylvania. Besides articles on comparative religion, he is author of *English and American Poems* (1888); *Songs of Asia Sung in America* (1896); *Marvelous Birth of the Buddhas* (1899); *Hymns of the Faith* (*Dhammapada*) (1902); *Buddhist and Christian Gospels* (1902: 4th ed., 1908-09); *Buddhist Bibliography* (1903); *Buddhist Texts Quoted as Scripture by the Gospel of John* (1906-11); *Fairmount Park and Other Poems* (1906); *A Duet with Omar* (1913).

EDMUNDS, GEORGE FRANKLIN (1828-). An American lawyer and legislator. He was born at Richmond, Vt., was educated in a common school and by a private tutor, studied law, and in 1849 was admitted to the bar. He settled in Burlington in 1851 and from 1854 to 1859 was a member of the State Legislature, being for three years Speaker of the Lower House. In 1861-62 he served in the State Senate and was President pro tem. When the Civil War broke out, he was a member of the State

Convention which met to form a coalition between the Republicans and the War Democrats, and he drew up the resolutions adopted by that convention as the basis of union. At the death of Solomon Foot, in 1866, Edmunds was appointed to fill the vacancy from Vermont in the United States Senate, and held office until his resignation in 1891. In the Senate he served on the committees on Commerce, Public Lands, Pensions, Retrenchments, and the Judiciary. He was a member of the Electoral Commission (q.v.) in 1877, was for several years at the head of the Senate Judiciary Committee, and was President pro tem of the Senate during Arthur's administration. He was the author of the Anti-Polygamy Act of 1882, known as the Edmunds Act, of a somewhat similar Act passed in 1887, and of the Anti-Trust Law of 1890. After retiring from the Senate he practiced law and attained great eminence as a constitutional lawyer. In 1897 he became chairman of the Monetary Commission appointed by the Executive Committee of the Indianapolis Monetary Conference.

EDMUNDSON, GEORGE (1848-). An English clergyman and historian, born in Redcar, York, and educated at Magdalen College, Oxford. He was ordained a priest of the Church of England in 1874, but is best known as a special student of the history of the Low Countries and of South America. In 1901-04 he was employed in preparing the British case in the Guiana-Brazil boundary dispute. He contributed several chapters to the *Cambridge Modern History* and published: *Milton and Fendel* (1885); *Archbishop Laud and his Work* (1905); *Anglo-Dutch Rivalry in the First Half of the 17th Century* (1910, Ford Lectures at Oxford); *The Church in Rome in the First Century* (1913, Bampton Lectures).

EDMUNDSTON. A town and the county seat of Madawaska Co., New Brunswick, Canada, situated on the Canadian Pacific, Grand Trunk Pacific, and Temiscouata railways (Map: New Brunswick, A 1). It contains a Roman Catholic convent and is the centre of a lumbering and farming district. The town owns its water and electric-light and power systems. Pop., 1901, 444; 1911, 1821; 1914 (local est.), 2600.

EDOM (Heb. *edôm*, red, Gk. *Ἰδομᾶτα*, *Idomaia*). According to the Old Testament, which places Esau in possession of Edom, the latter becomes one of the names of Esau, fancifully explained because of the "red" pottage given him by his brother Jacob (Gen. xxv. 29-34). (See *ESAU*.) The ruddy hue of the sandstone cliffs may have had something to do with the naming of the region. The name, under the form *Udumu*, occurs in the Tell el-Amarna Tablets (c.1400 B.C.). It is designated as a city, and since in later Assyrian inscriptions it is sometimes designated in the same way, though also as a country, it has been concluded that the district received its name from its chief city. Another and apparently older name was *Seir*, which is the designation of the mountain range. Originally in the possession of the Horites, it passed into the hands of the Edomite group. The latter, however, did not drive out the former, but intermarried with them (Deut. ii. 22; Gen. xxxvi. 20-21).

Edom comprised a strip of country, 100 miles long by 20 miles broad, lying between the south of Palestine and the Gulf of Akabah (q.v.). It is a wild, mountainous region, with the desert on the east and west of it; but, rugged though

Consult: Winckler, *Geschichte Israels* (1895); F. Buhl, *Geschichte der Edomiter* (1893); A. Musil, *Arabia Petræa*, vol. ii. "Edom" (1908); Brünnow and Dowszewski, *Die Provincia Arabia*, vol. i (1904); Hoskins, *The Jordan Valley*

ED'SALL, SAMUEL COOK (1860-). An American Protestant Episcopal Bishop, born at Dixon, Ill., and educated at Racine College and Western Theological Seminary. He was ordained to the priesthood in 1889 and in the same year was appointed to the rectorate of St. Peter's Church, Chicago. After an activity here of 10 years he became Missionary Bishop of North Dakota, serving until 1901, when he was elected Bishop of Minnesota. He wrote *Prayer Book Preparation for Conformation* (1898).

EDSON, CYRUS (1857-1903). An American physician, born at Albany, N. Y. He studied at Columbia and the College of Physicians and Surgeons, in 1882 was appointed assistant sanitary inspector of New York City, and rose to be health commissioner. In 1893 he was appointed health commissioner of the State of New York. He was three times elected president of the Board of Pharmacy of the City and County of New York. He was known as a bacteriologist, invented several surgical instruments, and wrote a large number of articles on sanitary and medical topics.

EDUCATION (Lat. *educatio*, from *educare*, to rear, nourish, bring up, from *educere*, to lead out, from *e*, out + *ducere*, to lead). In a general sense, the development of the whole nature of man, physical, intellectual, and moral, through interaction with every phase of his environment; in a narrower and more usual sense, the development of the powers or capacities of the mind through special processes of training. No one application of the term has now or ever had a common acceptance, for it may have a variety of special applications. Quintilian applied it to the general processes of education; the child's earliest years, in contrast with the formal school processes, called instruction. The Greek idea of education included both the early process of training, or formation of habits based upon authority, and the later process of instruction, or the rationalizing of the habits formed. This general conception is formulated by Plato as follows: "Good education is that which gives to the body and to the soul all the perfection of which they are capable." For many years the popular idea has been limited to the narrower one of instruction, but recently, under the influence of the conception of evolution, it has been realized that every stimulus that sets up a series of reactions in the human organization has some influence in shaping the final character. However, such a conception is too vague to be of any general value, and some such formulation as the following is now of common acceptance: Education includes all those processes consciously adopted by a given society for realizing in individuals the ideals which are approved by the race or by the particular group; while instruction includes all those definite means and methods adopted under the direction of a particular institution, usually the school, for accomplishing certain particular ends, wholly or for the most part of an intellectual character. The greater part of this article will be devoted to a sketch of the theory of education, with enough detail of the actual practice to illustrate the true nature of the theory. This presentation is supplemented in the articles relating to the prominent educators of the past, especially those about Abélard, Alcuin, Aristotle, Basedow, Comenius, Fellenberg, Fröbel (or Froebel), Herbart, Locke, Horace Mann, Montaigne, Pestalozzi, Plato, Quintilian, Rabelais, Ratichius, Rousseau, Herbert Spenser, Sturm. A further discussion of the principles of education, especially in relation to their application as an art, is given in the articles on PEDAGOGY and on PSYCHOLOGY. The subject of educational method, treated primarily in the article on PEDAGOGY, is treated in some of its aspects in the articles on BASEDOW; COMENIUS; FRÖBEL; HERBART; JACOTOT; LANCASTER, JOSEPH; NORMAL SCHOOL; OBJECT TEACHING; PESTALOZZI. The present condition of educational systems

and practices, together with a sketch of their historical development since the Reformation, is given in the article NATIONAL EDUCATION, SYSTEMS OF. Special phases of the existing educational systems are discussed under the titles: AGRICULTURAL EDUCATION; CHAUTAUQUA; COLLEGE; COLLEGES, AMERICAN; COMMON SCHOOLS; CURRICULUM, EDUCATION, COMMERCIAL; EVENING SCHOOLS; GRAMMAR SCHOOLS; HIGH SCHOOLS; GYMNASIA AND REALGYMNASIA; INDUSTRIAL SCHOOLS; INFANT SCHOOL; MONITORIAL SYSTEM; MONTESSORI METHOD; NORMAL SCHOOL; PROFESSIONAL EDUCATION; REALSCHULEN; TECHNICAL EDUCATION; UNIVERSITY, UNIVERSITY EXTENSION. The more important present educational tendencies and problems are considered under the topics COEDUCATION; COLLEGIATE EDUCATION FOR WOMEN; COLLEGES, AMERICAN; EDUCATION, COMMERCIAL; CURRICULUM; ELECTIVE COURSES; GRAMMAR SCHOOLS; KINDERGARTEN; MANUAL TRAINING; OBJECT TEACHING; NORMAL SCHOOL; PARISH SCHOOL; PEDAGOGY; SCHOOLS. Certain aspects of these topics are also treated in the articles relating to the special universities, colleges and public schools, and in the sections on education in the articles BELGIUM, FRANCE, GERMANY, GREAT BRITAIN, ETC.

Types of Education. The definitions given above indicate that education has two phases, more or less distinct. First, it is the physical and psychological development of the individual, solely with reference to these activities within themselves; and, second, it is the process of adjusting the human being to his social environment—to the ideals and customary practices of his fellows. So far as the process is concerned, these two phases are not distinguishable, but are rather complementary; whereas, in reference to the conception and the realized purpose, they are clearly differentiated and often are in conflict. Its history presents many aspects that find a common explanation in the varying emphasis placed upon the individual and social phases, together with the relative importance which the activities for supplying food, clothing, and shelter assume at any given stage of culture. Among primitive people education was largely practical and centred in the family group. It was essentially a training given the child, ordinarily by his parents, in the customary processes of supplying the needs of food, clothing, and shelter. (Consult Letourneau, *L'Évolution de l'éducation dans les diverses races humaines*, Paris, 1898, and Webster, *Primitive Secret Societies*, New York, 1908.) These activities necessitated a variety of ceremonial observances relating to every interest in life in order to secure proper adjustment to the spirit world, omnipresent to the savage and the barbarian. As a priesthood developed, priests had instruction in the preservation and explanation of tradition and ceremonies, as distinct from the broader ceremonial education of all the people. Out of this esoteric training of the priesthood and the attempt to construct cosmographies grew in time philosophy, science, and literature, and the higher types of education. Such types are best illustrated by the Hindus, the Egyptians, and the Jews. There developed, too, along with these early types of priestly instruction, a caste system of education for the masses of the people, that gave, in addition to the religious ceremonial education mentioned, a training in the practical affairs

of life. In such a system the training was given by parent to child in the activities to which he had been growing division of labor. The caste system of education was highly developed by the Egyptians and the Hindus and, with the latter at least, has persisted until recent times. While the caste organization of society was never reached by the Chinese, they did develop a system of industrial education akin to that of caste societies. The Chinese were the first of existing nations to develop a general system of literary education. While it does not of course affect all the people, it is at least open to all and does reach large sections of the population. It is literary, dealing primarily with the classics, organized as a preparation for the civil service, tested and controlled by a series of examinations. The successful competitors in these examinations become public officials, and the conduct of the government is placed in the hands of those who are by the process of selection most opposed to corruption and to progress. This system, first organized in the time of Confucius, has undergone no radical change for the past 1000 years. The recent trouble with the Western nations incident to the Boxer uprisings has given opportunity for the influences gradually creeping in through contact with the Westerners to affect the examination system, and radical changes are now going on. The ancient Persians, the Greeks, and the Romans developed a national type of education which at first was largely military. But its political aspect expanded with Greek and Roman political life until individualism found expression in an education both liberal and practical. Since that time the process has been growing more scientific, synthesizing these several modes, influenced in a varying degree by the ideals of Christian religion.

Historical Sketch of the Theory of Education. The Greeks were the first to work out a theory and practice of education based upon scientific principles rather than upon religious beliefs and ecclesiastical ceremonies. The purpose of the early education, with both Athenian and Spartan, was preparation for the duties of citizenship, military, political, and religious. With the Athenians their activities provided for intellectual and æsthetic development, illustrated in the drama, religious ceremonial, the symposium, the choral performance, etc. From the middle of the seventh century B.C. there were at Athens elementary schools of a twofold character: one was the music school, which in time embraced instruction in reading and writing; the other was the school for gymnastics and dancing, which for earlier years was called the *palaestra*, and, for the period of adolescence, the *gymnasium*. The training in gymnastics was not a direct military training, but was aimed to produce a beautiful, symmetrical, agile, and sound body through various exercises, chiefly running, jumping, discus throwing, javelin casting, wrestling, and boxing. Nor were the music schools designed to produce performers; they were rather schools of expression. "Gymnastic for the body, music for the soul," was Plato's summary of the process of education, each in its way to produce harmony of development. In the fifth century B.C. intellectual education was much broadened by the Sophists, and much greater scope given to individualism. It became more largely a literary process, differen-

tiating into the rhetorical or oratorical and the philosophical. Of the former, Socrates, Aristotle are the chief exponents of the latter. In the *Republic* of Plato, which may be termed the first scientific treatise on the subject, elementary education consists of training in gymnastic and music, including letters; secondary, of the study of arithmetic, geometry, music, and astronomy; and higher, of dialectics, or philosophy. The elementary studies produced a harmony of body and soul that was the basis of all virtue; the secondary led to unity of thought; and the higher led to the contemplation of pure being, the union of truth and beauty. The purpose of this education was to obtain an insight into the essential nature of things. In this treatise, together with that contained in the *Laws*, there is found the fundamental distinction between the liberal and the practical education, between the different stages of education, and between the groups of study so long recognized under the terms *trivium* and *quadrivium*. It is indicative of the importance of education in Greek thought that, with Plato and Xenophon and Aristotle, it finds a place in the discussion of the science of government. Not only is education to be intrusted to the state, it is the state's most important function. However, in practice the philosophical influence on education but reinforced the tendency towards individualism; for the formation of the philosophical schools still further weakened the Greek commonwealth, instead of strengthening it. The influence of the

The rhetorical education of the later Greek period is best represented by Isocrates. It is this type that is reproduced at Rome and best presented in Cicero's dialogue *On Oratory* and Quintilian's *Institutes of Oratory*. The early Roman education consisted of a training for the practical affairs of life, economic, military, and political, for which little or no literary instruction was necessary. The Laws of the Twelve Tables, with the biography and legends of historical characters, furnished all the subject matter of this stage, aside from the training given in practical duties. Under the influence of the Greeks a literary education was substituted, and with the early Empire there was developed an elaborate system consisting of an elementary school, the *ludus*, which had existed from early times, the grammar or secondary school, the rhetorical schools, and, in certain centres, as Rome, Constantinople, Marseilles, etc., a higher institution resembling the modern university. With the loss of liberty under the Empire, oratory lost its chief inspiration, and education became largely a process of formal training, in which even literature became a study of form. Though many of the emperors—among them Vespasian, Hadrian, and Antoninus—were patrons of education, learning ceased to have any profound influence on the character of society. Towards this formal intellectual life, represented in Greece by the philosophical schools, and in Rome by the rhetorical schools, the early Christian fathers were rather favorably inclined, notably Clement of Alexandria, Origen, and Basil; but later the attitude of the Christian teachers became distinctly hostile. Especially is this true of the Latin fathers, as represented by Tertullian and St. Augustine, the latter being responsible for the edict of the Council of

Carthage, which forbade the study of pagan literature by the bishops. The ascetic spirit was another cause of the opposition to learning and culture, since both were essentially worldly, and hence evil. Yet to monasticism (q.v.) is chiefly due the preservation of learning during the centuries known as the Dark Ages. The rules of St. Benedict provide for the copying of manuscripts and the reading or the hearing of the Scriptures as a part of the daily routine of monastic life. Yet during some centuries many monasteries existed in which no reading or writing could be done. On the other hand, the monasteries sheltered some at all ages who had an abiding interest in literature and learning. During the earlier centuries of the Middle Ages this was especially true of those monasteries that transmitted the Grecian influence. St. Basil, in . . . , to the extreme asceticism of Egypt an . . . , had introduced a more intellectual element into Grecian monasticism; this was carried by Cassianus to southern France, and from there by St. Patrick to Ireland. Celtic monasticism dominated the British Isles during the seventh and eighth centuries, and thence the intellectual interest was carried to France and the Continent by Alcuin in the eighth century, and by John Scotus Erigena in the ninth. Scotus marks the beginning of Scholasticism (q.v.), though the scholastic movement can hardly be said to have been general before the twelfth century, and it culminated in the thirteenth. Scholasticism was the first of the great intellectual revivals, unless the movement under Alcuin and Charlemagne can be considered a preliminary revival of interest in learning, organized now with the form if not the content of ancient times. (See ARTS, LIBERAL.) Scholasticism was distinctly an intellectual movement, beginning with the discussion of the Platonic and Aristotelian problems of the nature of ideas, and ending with the systematization of all thought in the form of a theological philosophy. However, the intellectual interest was clothed in a theological form, and partook of a logical rather than a rhetorical character; in fact, its exponents sought rather to avoid literary form for severe and precise statement. Out of the scholastic movement came the early universities, at least the one at Paris and its offshoots. In them intellectual interests were provided with a home, and education obtained that institutional foundation which had been wanting since the decline of Roman culture and government. This conception of the formal character of the subject matter of education and the disciplinary character of its method prevailed both within and without the universities until the Renaissance of the fifteenth and sixteenth centuries. At this time the world awoke to the fact that there were other interests in life besides the religious, and that there was a vast literature much more varied and complete than that upon which interest had been centred for many generations. Intellectual interests were stimulated, and the conception and purpose of education were broadened by the activities of such men as Petrarch, such teachers as Vittorino da Feltre, and finally by the teaching of the universities, though they had responded somewhat slowly to the new influences.

The Renaissance emphasis upon the linguistic character of education introduced new secular interests into the then prevalent system. In

early years instruction had to be of a religious character and hence centred in the religious literature, which demanded a knowledge of the Latin language. Higher instruction was, to a large extent preparation for controversial life in connection with religious doctrines and literature and hence had also to be linguistic in its elements. The Renaissance interest in the rudimentary sciences and in the æsthetic element in literature was almost wholly eliminated from organized educational efforts; while, in addition to this, the religious conflicts introduced by the Reformation movement so agitated and demoralized the social, domestic, and political conditions of the times, that organized education, subjected like all other institutions to the distressful storms of the period, suffered greatly in the general upheaval. Nevertheless, during this agitated sixteenth century there were educational influences at work, which crystallized into definite school organization and procedures, best typified by the work of Johannes Sturm (q.v.) and later by that of the Jesuits. Sturm, who was the head of the Strassburg Gymnasium from 1537 to 1582 and was inspired by the work of the Brethren of the Common . . . , ten years' course of study, . . . and Latin grammar, rhetoric, and literature. Not till late in his 45 years' experience did he introduce any study of mathematics into the last years of his curriculum. Sturm's ideas . . . and subject matter were . . . the developing school system of the German states. His course of study, slightly amplified, was adopted in the higher schools soon to become common under the term *gymnasia* (q.v.). His methods, embodied in textbooks, were perpetuated and popularized in a similar manner, not only in German states, but elsewhere. Through Roger Ascham, the tutor of Queen Elizabeth . . . of Sturm, similar educational ideas and practices were adopted as a characteristic feature of the public or grammar schools then being founded to some extent in England. In the latter part of the sixteenth century the Jesuit Order formulated its *Ratio Studiorum* (q.v.), embodying many ideas similar to those of Sturm. Their numerous schools were the most efficient and popular up to the middle of the eighteenth century, by the end of which there were 612 colleges, 157 normal schools, and 24 universities. Sturm and the Jesuits only organized the humanistic educational ideas of the Renaissance; and the resulting education was in its content a wholly literary one of the extremely classical type, while its purpose and discipline were largely determined by religious influences. Sturm was a Ciceronian, and it was wholly with the purpose of producing the ability to use the Ciceronian Latin and of securing the discipline entailed by this process that the dominant educators of the sixteenth and seventeenth centuries labored. During this period there were not wanting, however, those who protested against this formal education and insisted that the purpose of the study of the classical literature was the possession of the knowledge contained therein and not yet to be found in any of the vernacular literatures. Erasmus, though a humanist, took this position; but the two Frenchmen Rabelais (q.v.) and Montaigne (q.v.) were the chief of these, while about the middle of the seventeenth century John Milton issued his *Tractate on Education*,

which demanded that the whole range of the sciences and arts should be studied in the Greek and Latin literature and propounded this notable definition of education, viz., "I call a complete and generous education that which fits a man to perform justly, skillfully, and magnanimously all the offices, both public and private, of peace and war." By Milton's time, however, there was abroad a new spirit in education, in which he participated to some extent. This was the same spirit that was represented in philosophy by Descartes and in science by Bacon; in education the great exemplar was Comenius (q.v.). The educational influence of Comenius was expressed (1) in broadening the conception of education beyond the narrow literary and linguistic confines until it included the whole realm of knowledge, as conceived in the popular pansophy of the time; (2) in organizing education into a definite institutional hierarchy and systematizing its subject matter into a definite course of study, which included the elements of all the sciences, both natural and social; (3) in introducing improved methods of instruction based on conceptions—more or less erroneous, it is true—of natural processes. These ideas were embodied in a series of textbooks, the most important of which was the *Orbis Pictus* (q.v.). Comenius was not alone, even in the educational field, in standing for these new ideas. Ratichius (q.v.), or Ratke, had preceded him, but had exerted little influence, owing rather to his temperamental defects than to the novelty of his ideas. Even in the preceding century Rabelais and Montaigne had led in the criticism of the traditional educational ideas and practices, and had had little influence on school work or little knowledge of the technique of the educational process, both opposed the extreme classicism of the time, protested against the acceptance of erudition as the aim of education, of the formal linguistic discipline as the purpose of the study of the classical literature, and held even more broadly that experience in life gave the purpose to education, so far as it was a definitely organized process. Rabelais and Montaigne were significant rather as protestants, giving an embryonic formulation to a conception of education to be further developed and made practical by such men as Comenius. The practical aspect of the Comenian movement was limited to the seventeenth century, though the line of thought was continued. In 1693 John Locke published his *Thoughts, Concerning Education*, which continued the general thought of Comenius, though without recognizing the importance of a scientific rather than literary curriculum, as might have been expected. This work of Locke has probably been of wider influence than any other treatise on education written in the English language, unless it be Herbert Spencer's *Education*. Locke emphasized the moral and physical aspects of education, in these respects exerting a profound and lasting impression on English education, both under the tutorial system which he approved and in the public schools. He had in mind the education of an English country gentleman of his time and gave little attention to the philosophical aspect of his education. This is treated in the more general work on *The Human Understanding*, and its influence passed through the writings of the empirical school of philosophy until it reached Rousseau. Jean Jacques Rousseau (q.v.) is the most com-

manding educational figure in the eighteenth century. In 1762 appeared his *Emile*, which was destined to direct the current of educational thought for a century. His dominant thought was "education according to nature," a shibboleth which had a variety of interpretations; it meant, primarily, that the influence of human society is evil, that education should seek to eliminate all social influence, that education should shield the mind from error and the heart from evil, and this largely by isolating the child; it meant, further, that the "nature" to be considered in education was the nature of the child, not nature in the Comenian and Baconian sense of the general processes and phenomena of the physical and biological worlds, and this is its most important educational meaning; but it also meant nature in this latter sense as well, the world of things, since it was only the education that came from things that was wholly good. This last interpretation of the naturalistic doctrine led to the complete rejection of literary and linguistic education, and in time to the organization, for elementary education, of a curriculum more suited to the needs of the child, drawn from those phases of his environment with which it came into immediate contact, such as geography, nature study, number work, and manual occupations. While Rousseau's ideas were most radical and were often stated in such paradoxical form that they provoke dissent and violent opposition, he more than all others is responsible for these fundamental conditions of modern education: that all educational processes must start from the child's own interests and activities; that education is a process having several distinct stages, and that the subject matter and methods of education should be appropriate to each stage; that the age of adolescence is the vital period in education; that education is moral, physical, and social rather than a merely intellectual process; that knowledge of child nature in general and of the children dealt with in particular is the most important part of the equipment of a teacher; that manual labor or trades should be taught for their educational as well as for their moral and practical value.

The exaggerated, somewhat visionary, and often erroneous ideas of Rousseau were systematized and made practical during the latter part of the eighteenth century and first half of the nineteenth by groups of educators led by such men as Pestalozzi (q.v.), Herbart (q.v.), and Fröbel (q.v.). There is a wide divergence in the interests and the character of the work of these various groups, but they agree in one fundamental principle, which characterizes and unifies all their efforts and all this period of educational advance. This principle is that the "nature" which is to control education is the nature of the child. Pestalozzi states the aim of the entire group when he says that his whole purpose is to "psychologize education." Pestalozzi's approach was empirical, and his efforts were wholly practical. Herbart's approach was both philosophical and scientific, though it is in this latter aspect that his influence has been permanent, through the development of the scientific study of psychology. Fröbel's approach, late, in its experimental and psychological aspects. Fröbel's approach was primarily philosophical through the connection of the theory of evolution with education, as seen in his *Education of Man and Education by Development*.

However, his great influence was on the practical side, and it is for the application of these new theories of education to the first few years of the child's life by means of a new educational institution, the kindergarten (q.v.), that the name of Fröbel will always stand. But whether this conception of education was stated in philosophical or even metaphysical terms, as with Kant, Herbart, and others, or in practical or empirical terms and concrete methods, the underlying conception and the general influence were the same. The psychological tendency in education was based upon a more intimate knowledge of child nature and a study of child activities; it was characterized by a broader sympathy with childhood and child nature; it turned attention from the advanced phases of education and centred it upon the elementary stage; it tended to break down the bookish character of education and substituted the objective side of the child's immediate environment (see OBJECT TEACHING); it furnished a great stimulus to the movement for universal education; it concentrated educational interests in the problems of method, both psychological and practical. The beliefs of many, especially of those under the influence of Pestalozzi, were extreme in this respect. Pestalozzi's thought was that any mother, with the methods which he had formulated, could, despite no special training or knowledge, educate her own children without the aid of books or any of the usual paraphernalia of the schoolroom. This is extreme reaction from that conception of education, dominant since the Renaissance, in which education was the acquisition of knowledge, especially linguistic and literary. Pestalozzi defined education to be "the harmonious development of all of the powers of the child," a definition which expresses the central thought of the entire psychological tendency—that education is the process of the development of the individual.

During the second and third quarters of the nineteenth century the reaction against the extreme individualism of the earlier period affected educational thought as well. In contradistinction to the psychological, this may be termed the sociological conception of education and emphasizes the thought that education is not only the development of the individual, but that it is also the fitting of the individual to his social environment, actual and idealized, and hence that it is the development of society as well as of the individual. Auguste Comte in his *Positive Polity* (1851-54) and Herbert Spencer in his *Education* (1861) may be taken as the leaders in this movement, though Pestalozzi in his *Leonard and Gertrude*, published from 1780 to 1790, also emphasized this aspect of education. This sociological interest has centred in two points: (1) in a broader educational purpose than that expressed in psychological terms, and in this it has but put into educational terms the developing ethical, political, and social thought of the nineteenth century; (2) in a revision of the school curriculum, through the introduction of new subjects, chiefly of a scientific character, and in a modification of emphasis and organization. In its earlier stages the movement was largely a result of the expansion of the organized branches of human knowledge and the demand made by the new professional and industrial opportunities for a wider knowledge and a training different

from that afforded by the old literary education. The change in the curriculum of the colleges as well as of elementary schools; the rapid development of institutions of the type of American high or secondary schools, of technical, manual-training, and professional schools; the introduction of the system of elective courses (q.v.) into colleges; the important position given to the various natural and social sciences; the attention devoted to the organization of all the school curricula and the school systems—are all aspects of the sociological tendency, the influence of which is leaving its impress on the educational systems throughout the world, many of which have been reorganized within the last ten years to meet the changing social demands and the consequent changing conceptions of education.

Education as a Science. Not to be clearly distinguished from this sociological tendency is a more comprehensive view of the past decade, which has aimed to combine the essential truths of the above tendencies and hence may be called the eclectic or scientific view. It recognizes the coordinate value of method and subject matter, of the process of the development of the mind, and of the relation of educational activities to society. It avoids the controversial character of the parent tendencies and aims rather at scientific exposition. It is based upon the results of both psychological and sociological sciences and has influenced education in the more scientific formulation of the principles of method and curriculum in their mutual relations. The following definitions set forth this conception: Education is "the organization of acquired habits of action and tendencies to behavior which shall fit him [the child] to his social and physical world"; it is the "making over of experience and giving it a more sociological value through increased individual efficiency or better control over one's own powers"; it is "the adjustment of the child to the spiritual inheritance of the race." These three definitions, given respectively by the late Prof. William James of Harvard, Prof. John Dewey and President Butler of Columbia University, give the idea of the foremost leaders in educational thought in the United States at the present time. The study of education is now recognized as a science in that it has a body of data quite as definite as that of many of the applied sciences and as well-defined methods of dealing with such data. It is not a science in the sense of having any universally accepted group of principles as a basis of study, and in this it is in the same status as history, sociology, and most of the social sciences. Its recognition as a science has led to the establishment in most of the leading universities of departments of education of a character wholly different from that of the professional training normal schools (q.v.). Of the last importance is the influence exerted by the Government Commissioner through the Bureau of Education at Washington. Dr. W. T. Harris, by his official publications, private editorial work, and public addresses, assumed the leadership originally contemplated in the establishment of the department, and this position has been further developed by his successors. As a result of this professional and scientific study of the subject, the character of the teaching profession has been greatly improved, and more intelligent consideration has been given by the public to

the problems of local school organization, supervision, textbooks, methods, and the relations of teachers, as well as to the broader subject of education as a matter of public policy.

Bibliography. There is no more conclusive evidence of the importance and the scientific character that the study of education assumed during the nineteenth, and continues to hold in the present, century than the very extensive literature of the subject. A very few titles selected from this extensive list may be here mentioned. Hall (Boston, 1893), Sonnenschein (New York, 1891 and 1895), Monroe (New York, 1897), Cubberly (New York, 1902), have each published a *Bibliography of Education*. *The Bulletin of the Books on Education in the Libraries of Columbia University* (New York, 1901; new ed., 1911) also furnishes an extensive bibliography. Since 1910 there has been issued in 5 vols. a *Cyclopædia of Education*, ed. by Paul Monroe, which supplies a gap in this field in English and may fitly be compared with Buisson's *Dictionnaire de pédagogie* (Paris, 1887; 2d ed., 1903-11), or Rein, *Encyklopädisches Handbuch der Pädagogik*, or Schmid, *Encyklopädie des gesamten Erziehungs- und Unterrichtswesens* (10 vols., Gotha, 1886-87). Sonnenschein has published a brief *Cyclopædia of Education* (London, 1889). Other works which, while not equal in scope to the cyclopædias mentioned, are fairly comprehensive in character, are: Barnard, *American Journal of Education* (Hartford, 1855-81); Appleton, *International Education Series* (45 vols., New York, 1885 et seq.); Heath, *Pedagogical Library* (28 vols., Boston, 1886 et seq.); Scribner, *Great Educator Series* (10 vols., New York, 1892 et seq.); and the *Reports of the United States Commissioner of Education* (Washington, 1867 et seq.); *Special Reports on Educational Subjects*, issued by the English Board of Education since 1896-97. Several universities also issue works on different phases of education, among which may be mentioned the *Teachers College, Columbia University, Contributions to Education*, now containing nearly 60 vols. For the very numerous French and German works on the history of education, the reader is referred to the bibliographies given above. Among the best are those by Schmid, Schmidt, Raumer, Paulsen, and Graserger. Raumer, *Geschichte der Pädagogik*, has been translated for the most part in Barnard, *German Teachers and Education* (Hartford, 1878). Compayré, *History of Pedagogy*, is published in translation by Payne (Boston, 1886). On ancient education the best English works are: Laurie, *Historical Survey of Pre-Christian Education* (London, 1895); Monroe, *Source Book in the History of Education for the Greek and Roman Period* (New York, 1901); Mahaffy, *Old Greek Education* (ib., 1882); Davidson, *Education of the Greek People* (ib., 1891); Leake, *Schools of Hellas* (London, 1909); Wilkins, *Roman Education* (Cambridge, 1905). For general histories of education, consult Monroe, *History of Education* (New York, 1911); Graves, *History of Education* (3 vols., ib., 1909-13). On modern education a few of the best historical and descriptive works are the *Reports*, by Matthew Arnold (London, 1861 et seq.); the publications of Henry Barnard on *National Education* (New York, 1857-73); the volumes in the general series referred to above; Russell, *German Higher Schools* (ib., 1899); Balfour, *Educational Sys-*

tems of Great Britain and Ireland (London, 1912); Quick, *Educational Reformers* (New York, 1890). In addition to the treatment given in the above references, the works of the following authors relate wholly or in part to theory of education: viz., Plato, Aristotle, Cicero, Quintilian, Plutarch (the discussions on education by these writers are given in selections in Monroe's *Source Book*, mentioned above), Comenius, Rabelais, Milton, Locke, Rousseau, Pestalozzi, Richter, Rosmini, and Spencer. For statement of present formulation of theory, consult: Harris, *Psychologic Foundations of Education* (New York, 1898); Butler, *The Meaning of Education* (ib., 1898); James, *Talks to Teachers* (ib., 1899); Dewey, *The School and Society* (Chicago, 1899); *Ethical Principles Underlying Education* (Ann Arbor, 1894); Butler, *Education in the U. S.* (Albany, 1900). See, in addition to the titles referred to in the first paragraph of this article, ACADEMY; DEGREE; MILITARY EDUCATION (and articles on the various schools); MONASTICISM; POLYTECHNIQUE; REFORMATORIES; SCHOOLS OF LIBRARY ECONOMY; and the articles on the various universities.

EDUCATION, COLONIAL. A term used to indicate educational systems and practices in colonial dependencies. There is no special type either of ideas or of systems that can be indicated by this term, which consequently is used in a most general sense. However, of recent years it has become a very important phase of educational activity, since the various colonizing nations have established systems of schools as a valuable means in governing colonies and in bringing dependent peoples into closer sympathy with the home nation, or at least have accepted educational endeavor as a means of raising the standard of civilization of the subject races. Previous to the nineteenth century colonizing governments took little or no direct interest in education, and such efforts as were made were wholly those of the colonists themselves or of individuals and religious bodies at home. Such efforts naturally resulted in direct imitation of institutions existing in the parent country and find their best illustration in the American colonies of England previous to the Revolution of 1776. Here the elementary or dame school, the secondary or grammar school (q.v.), and the college were English institutions transferred to American soil, and it was not until well into the eighteenth century that these English institutions were so modified that they became schools, known as the district school, the academy, and the American college. Of these the college was most distinctly American from the first and hence underwent the least change. Naturally, at the present time, the character of education in the colonies of any nation or in any particular colony of a given nation, is determined by the general character of the colonial government. The colonies of Great Britain, as in the furthest developed and most systematized, best present the various types. In self-governing colonies, those possessing responsible governments, the educational system is wholly under the control of the colonial government and is only to a slight extent an imitation of the English institutions. Hence the educational systems of the Australian and Canadian provinces do not differ in the character of their origin or of their control from those of the States of the American Union.

There is, it is true, a higher degree of central control in all of these than in the systems of American commonwealths, but this is in no wise connected with the home government in London. In the second class of colonies that possess some representative institutions, but in which the public offices are controlled by the home government, the most important educational institutions are for the most part transplanted English institutions, modified in non-essentials to suit local conditions, supported from colonial revenues, and controlled by the home-appointed colonial officials. Profiting by earlier experiments, especially in India, more regard is now had for existing educational institutions, practices, and native institutions are fostered, and the two types of schools—the English schools and the vernacular ones, the former being for the most part secondary and higher schools, to which greater attention is given. India furnishes a good illustration of this. In 1911 there were enrolled in public elementary schools 4,625,890 pupils, or 2 per cent of the population, while only 899,588 were enrolled in public secondary schools and 31,447 were enrolled as students in colleges. In the crown colonies, those wholly under the control of the home government, a somewhat similar condition exists. English schools are established, native schools are assisted, and numerous private, especially missionary, schools are found. As in the previous class of colonies, greater attention is paid by the authorities to the English school than to the native, and consequently to secondary and higher education than to elementary. This condition, which is now being reversed, has resulted from the fact that the elementary schools have been begun largely by missionary or native effort, and the government has followed the home policy of assisting them to some extent; while secondary and higher efforts have awaited the direct initiative and support of the government. In 1901 the Board of Education of the British government presented a special report of almost 2000 printed pages, giving a detailed account of education in the more important colonies. Greater interest is being shown in Imperial education as a result of the Imperial conferences of 1907 and 1911. Such conferences are to take place quadrennially, and it is proposed to establish an Imperial bureau of education to publish information on different aspects of education throughout the Empire.

The French government supports schools in most of its colonial dependencies, though none of the colonies are self-supporting, few have any extensive European population, and most of them are sparsely settled or are peopled by distinctly inferior races. Algeria is excluded from this statement, since no distinction is made in education between it and the other departments of France in Europe. So far as possible, the French system of schools is extended to the colonies, and in recent years the anticlerical movement of the mother country has helped to oust the educational work of the religious teaching orders; but on account of the conditions mentioned above there is little demand for secondary or higher education, save of a technical or professional character, and consequently most attention is paid to elementary schools. In French India, Indo-China, Annam, Cochinchina, Tonking, Madagascar, Congo, Mayotto, Réunion, Sénégal, Guinea, and the islands of

both the East and the West Indies, schools are maintained of both primary and secondary type. These secondary schools are usually normal or agricultural schools, infrequently the French Lycées. The schools are supported from local funds in most cases, but the French government also makes an annual subsidy.

The colonies of the German Empire have all been acquired since 1884, are sparsely settled, usually by distinctly inferior races, and are for the most part in the tropics. Hence the possibility of influencing the state of civilization by schools is slight. Besides missionary schools, the government supported in 1909 two schools at Togoland, four in Kamerun, a system of 40 or 50 schools in East Africa, and 11 schools in southwest Africa. The German government has adopted elaborate educational measures in its Chinese protectorate, and two departments have been established at Tsingtau—a preparatory school with a six-year course and receiving Chinese boys over 13 years of age, and a school of science with (1) a department of law and political science and (2) a technical department. Such schools as exist in the German possessions among the Pacific islands are maintained with a few exceptions by missionaries, both Protestant and Roman Catholic.

No other country has seen the importance of education as a means of colonial rule so clearly as the United States. Hence, in the short time during which the United States has held the colonies, great progress has been made. This progress is here presented in detail.

Hawaii. When the United States Government assumed control in 1898, there was less to do in regard to educational conditions than in any of the other recently acquired island territory, and less to do in regard to education than in almost any other aspect of Hawaiian conditions. In fact, the educational status of Hawaii is better, as regards illiteracy and school attendance, than that of many States of the Union. The existing government, then, has simply continued the established system and maintained its high standard. This exceptional condition, however, is largely due to the influence of Americans exerted over a long period. By the earliest missionaries in 1820 the natives were taught the alphabet, and many of them learned to read English before their own language was reduced to a written form. Within four years 2000 people had learned to read, a system of public schools had extended over the islands, and so great was the early enthusiasm that a large part of the population was in attendance. A seminary for the training of teachers, which still exists, was established in 1831; in 1833 the Oahu Clarity High School, which has since become the Honolulu High School, was founded, followed in 1836 by a boarding school for boys and in 1839 by an industrial training school. The Royal School for chiefs, founded in 1840, and since become a school for all Hawaiian boys, was the chief school for the teaching of English. Numerous other mission schools sprang up from time to time, and in 1839 the Roman Catholic missionaries established a system of schools. The first comprehensive system of laws was published in 1840, and these laws include a number of educational provisions. Most important of all was a compulsory-attendance law, with penalties for both parents and children for noncompliance, while it was further stipulated that no illiterate man or woman should "hold

office over any other man," nor could any illiterate person marry. In 1843 a department of public instruction was established with a minister of public instruction at the head, the first incumbent being the Hon. W. Richards, who was succeeded in 1847 by Rev. Richard Armstrong, father of Gen. S. C. Armstrong, of the Hampton Institute. In 1855 a board of education was substituted for the Minister of Education. In 1896 the system was again reorganized and placed under a minister and a board of commissioners, the Minister of Foreign Affairs being Minister of Public Instruction *ex officio*. Under the present scheme a board of six commissioners with a territorial superintendent of instruction has charge of education. A traveling normal inspector has the supervision of each of the three inspection districts of the island. The use of English has become all but universal, so that now more than 98 per cent of those attending school are instructed in English. All public schools were made free in 1888, since which time such schools have increased their attendance at the expense of the private schools until at present they educate more than two-thirds of the population. Owing to the decrease in native population, the absolute number of Hawaiian children in the schools has decreased one-half in the last 50 years. In 1913 there were attending public and private schools in the territory 32,938 pupils (25,631 public and 7307 private), divided as follows: Americans, 1239; British, 153; Germans, 270; Portuguese, 5497; Spanish, 678; Japanese, 10,990; Chinese, 3783; other foreigners, 1769; Hawaiians, 4290; part Hawaiians, 4146. The total number of public schools was 161 and of private 51, the total population in 1910 being 191,909. Of the 974 teachers (734 female and 240 male) 89 were Hawaiian, 191 part Hawaiian, 457 American, and the remainder of various nationalities. According to the report for 1911-12, the government expenditure for popular education was \$722,912.57, of which \$92,577.92 was for new buildings. The cost per pupil was \$30.43.

In addition to the elementary schools there are also maintained a territorial normal school at Honolulu, a high school at Hilo, and the Hawaii College of Agriculture and Mechanical Arts, established in 1907. The United States Department of Agriculture maintains an agricultural experimental station in Honolulu.

The Philippine Islands. At the time of the American occupation there was a Spanish law requiring two school-teachers for every 5000 of population, though in reality there were at the opening of hostilities between the Spaniards and Americans only half that number. In 1897 the Spanish statistics showed 2167 public schools for about 6,000,000 population. Education was almost wholly under the supervision of the religious teaching orders, especially the Jesuits, and schools were held either in church property or in the house of the teacher. The public-school system, which had been established by the Spanish government in 1863, was widely diffused throughout the archipelago when the Americans arrived. The course of instruction consisted of Christian doctrine, reading, writing, arithmetic, Spanish, geography, Spanish history, practical agriculture, the rules of deportment, and vocal music. The percentage of natives who could read and write varied greatly in different localities, in some instances being high and in others low. There existed a class of

the native population that was highly educated and very intelligent. The University of Manila had an attendance of more than 1000 in 1896, and in the period from 1800 to 1882 had graduated 2392 students. In the public colleges or secondary schools of the island there was a total attendance of 8070 in 1896, and in addition 1915 in 67 private Latin schools. During the first two years of American control of the islands little attention was paid to education, but on March 30, 1900, a department of education was established under charge of Capt. Albert Todd. For five months the schools thus remained under military control. Whenever practicable, soldiers were detailed to assist in giving instruction in English, books and supplies were furnished, and efforts were put forth to continue the native schools after the Spanish system. Little, however, was or could be accomplished. On Sept. 1, 1900, Dr. Fred W. Atkinson assumed office as the first General Superintendent of Public Instruction for the Philippine Islands. The Philippine Commission adopted a general plan for education recommended by the Superintendent, which became a law Jan. 21, 1901.

This law established a department of public instruction that should have control over all schools of public or semipublic nature. It provided for an executive head of the department, with an annual salary of \$6000; for 18 division superintendents of schools at salaries of from \$2000 to \$2500 per annum; for 1000 teachers of English from the United States, at salaries of from \$900 to \$1500; and for the establishment and maintenance of normal, agricultural, and manual-training schools. A general appropriation of \$400,000 for the first year was made for the construction and equipment of buildings, and of \$220,000 for the purchase of textbooks and school supplies. The law established a municipal council of four to six members, who should have duties similar to those of local school boards in the United States; and also a superior advisory board of education, to be composed of the General Superintendent of Public Instruction as president and four members to be appointed by the Philippine Commission. The duties of this board are largely of an advisory nature, but investigations are to be conducted by them and recommendations made to the Commission. The system is highly centralized in the hands of the Director of Education (formerly the General Superintendent), who is responsible to the Secretary of Public Instruction. The provinces are divided into 400 districts, each under an American supervisor. The opening of new schools, the selection of textbooks, the approval of building plans, and the course of study are all subject to the control of the Director.

The system of schools as now organized includes free elementary schools throughout the islands; free high schools in almost all of the 40 or more provinces; a normal, trade, and agricultural school in the northern, central, and southern portion of the archipelago; a higher school of commerce, and a school for the deaf and blind at Manila; and, finally, the University of the Philippines, established in 1908 and, with the exception of the College of Agriculture and Forestry, located at Manila. The plan of the elementary school calls for a ten-months school year, with four hours of instruction daily, and one hour's normal instruction for the native teachers. In addition,

during each summer vacation a four-weeks normal session for the native teachers is held in each provincial capital, under direction of the American teachers, and vacation assemblies are held at Manila and other important centres. In the summer and fall of 1901 almost 1000 American teachers arrived and were assigned work throughout the islands in places determined by local needs and safety, while at the same time more than 120 of the former soldier teachers were retained. The body of teachers is recruited each year by the addition of nearly 100 new teachers from America. A vacation assembly for American teachers has been held annually since 1908 at Baguio. During the first year more than 100,000 pupils and 5000 Filipino teachers were enrolled in the day schools, and 20,000 adults received instruction in the evening schools. In 1911-12 the educational statistics were as follows: 3647 elementary schools with an average monthly enrollment for the year of 391,476 pupils; 38 high schools with 3599 pupils; 200 municipal manual-training shops; 35 provincial trade and manual-training schools; 664 American and 7696 Filipino teachers were engaged under 444 supervising teachers, 40 division supervisors, 2 assistant directors and 1 director of education. In the elementary schools much attention is given to industrial training, especially in the native industries, and valuable work is being done by the introduction of gardening. In all types of schools athletics play an important part as a civilizing influence to which the natives readily adapt themselves. The University of the Philippines consists of the following colleges: Medicine, Liberal Arts, Veterinary Science, Law, Engineering, and Fine Arts at Manila, and the College of Agriculture at Los Baños. Except for the School of Fine Arts candidates for entrance must be graduates of secondary schools. The six colleges were attended in 1911-12 by 599 students and the School of Fine Arts by 801 students. A college of education is to be added. The expenditure for schools during 1911-12 was \$3,176,617.04. Instruction was given wholly in English and from English texts. Many improvements in administration have been made, such as better supervision of pupils, individual in place of mass instruction, the establishment of silent study for the old custom of studying aloud, and especially the change wrought in hygienic conditions. However, the chief work of the American administration of schools is to bring about a better spirit between the two peoples; and this is being done by the establishment of friendly relations between the American and the Filipino teachers, pupils, and parents. At least the mistake made by England in India, of concentrating efforts on higher education, is being avoided, and all efforts are centred in reaching the masses through the common school.

Porto Rico. The educational conditions in Porto Rico constituted one of the most serious elements in the situation which the Americans had to face on the assumption of control in the island in 1898. Excellent legal provisions for schools, including free tuition and compulsory attendance, had existed for many years, but for the most part these provisions had been dead letters. The excellent reforms in education introduced by the Spaniards in 1880 had been non-effective, and political and social conditions forbade any progress and prevented any interest

in such affairs. These conditions had been made much more critical at the time of the American occupation by the social and governmental disorganization incident to the war, and by the hurricane, which had destroyed most of the little interest the people had in schools, along with all ability to contribute to their support. Moreover, such interest as the people had had for generations was in the education of the upper classes and consequently in higher and secondary rather than elementary education. A few institutions of this higher grade existed, the most important of which were a collegiate institute, founded in 1880, with an attendance of 60, a normal school for girls, with an attendance of 50; and an industrial school for instruction in trade, with an attendance of 312. The methods of instruction and the management of the institute and normal, however, were so defective that after investigation these institutions were suspended by the American authorities, and other provisions made for carrying on such work. There were at that time, and still exist, a number of private colleges and academies, which for the most part are under religious control. One of these private institutions, La Sociedad Protectora de la Inteligencia, has for its object the education of poor young men who have failed in the examinations to enter the University of Spain to complete their studies. The last Spanish statistics, three months before the Americans took possession, showed a total of 555 schools, all but 26 of which were public. Of these 380 were for boys and 148 for girls. The total enrollment in public schools was 25,644, with an attendance of 18,243. The attendance in private schools was 980. This was out of a population of almost 900,000, of whom 300,000 were of school age. The entire population showed by the American census an illiteracy of 83 per cent.

In May, 1899, six months after the Americans assumed control, Gen. John Eaton, formerly Commissioner of Education for the United States, was appointed Director of Public Instruction, and an order was issued by the military government for the reorganization of the entire system. An insular board of education of five members was created, the president of which was to be insular superintendent of education. The order divided the island into school districts, somewhat like those in the United States, provided English supervisors, prescribed the manner of electing local school boards, established fines for nonattendance to duty on the part of the boards, and provided for district school taxes and the issuance of bonds. The municipalities were required to furnish buildings or quarters for the schools, distinct from the residences of the teachers. The schools were graded, a six years' course of study prescribed, the qualification of teachers defined and their salaries fixed, free textbooks provided for, and a high school, a normal school, and a professional school organized. Coeducation was not required, but was encouraged; and in the country districts where no provisions existed for the education of girls, it was provided that, upon request of parents, girls should be admitted.

While the law met with no opposition so far as internal administration was concerned, to a great extent it proved inoperative: for there was little or no response on the part of the local committees, and out of 800 towns of the

island, fewer than 20 made any attempt to effect a local school organization. Nevertheless, as a result of the influence of the military authorities, within five months there were more schools in operation than ever before, and a larger proportion of the school population receiving instruction. In June, 1897, there were 212 town schools and 313 country district schools in operation, with 426 country districts yet unprovided for. But out of a school population of 297,812 only 29,172 were enrolled, and 21,873 in actual attendance. More than 268,000 without school the close of the following school year, however, the number of schools had risen to 800, of which 409 were in rural districts. These schools accommodated 9000 additional pupils. The general government also supplied all textbooks free of expense to pupils and local boards. More than 100 American teachers were employed in the schools, and half that many native teachers were sent to the United States for the purpose of acquiring the language and some training in methods of instruction. Training and industrial schools have been established in the three most important cities. At present education is administered by a commissioner of education and an assistant commissioner; the island is divided into 43 supervisory districts, each under a supervising principal. In 1912-13 the number of different pupils enrolled in the common schools was 145,427 and in the secondary schools 1547. The number of teachers employed in the common schools was 1855 and in secondary schools 83. The total expenditure for school purposes in 1911-12 was \$1,366,810; the amount appropriated for education in 1912-13, \$1,902,712. The use of English as the medium of instruction is making rapid progress, especially in the graded schools. Much attention is given to the teaching of agriculture in the common schools, while manual work, sewing, and cooking are being more and more introduced.

The University of Porto Rico was established in 1903 and consists of the Normal School at Río Pedres, the College of Agriculture at Mayaguez, neither of which is of college standing, and a college of liberal arts, organized in 1910 and requiring the entrance qualifications set down by the College Entrance Board of the United States.

The greatest difficulty is the question of financial support. The military authorities raised the proportion of the public expenditures devoted to education from 6 to 12 per cent, but if the entire general revenue of the island had been appropriated for school work it would have been insufficient to offer instruction to all the illiterate youth of the land. Only very gradual improvement can be expected if no outside assistance is given to the island.

Cuba. The educational status of Cuba, at the time of the American intervention, was very similar to that of the other Spanish dependencies. There existed an excellent legal system, while the actual conditions were very deplorable. Such interest as existed was in reference to higher education, and admirable provisions were made for the more intelligent and wealthy classes. The University of Havana and a large number of secondary schools under private or religious control had been attended by large numbers of this class. The public schools were nominally free, but really depended on the tuition of pupils and consequently were patronized only by the well-to-do.

The system in force in 1899 was based on the Law of 1865 as modified by that of 1880. Every town of 500 inhabitants was required to support one elementary school for boys, and one, though incomplete, for girls; towns of 2000 inhabitants, two schools for boys and two for girls; and for every 2000 increase in population there was to be one additional school for each sex. This additional number was to include private schools, though at least one-third of all schools must be public. Secondary schools and kindergartens were provided for in cities of over 1000 population, and a normal school for the capital of each province. An admirable course of study was prescribed, but its actual administration and the textbooks used were under the inspection of the Catholic clergy. Attendance on either public or private schools was compulsory for all Spanish children from 6 to 9; the teachers in public schools were to be Spaniards. However, the municipalities had ceased, if they had ever done so, to pay any particular attention to these laws; no funds were voted, teachers were not paid, and their meagre revenue was drawn largely from tuition. The per cent of illiteracy under the American census taken in 1899 was 63.9 per cent. The latest Spanish school statistics were for the year 1893, two years previous to the outbreak of the last revolution. They show 35,000 children receiving instruction in the entire island in 898 schools. During the revolution most of these schools ceased to exist, if they had ever existed before. Those outside of provincial capitals and garrisoned towns were closed by order of the Governor-General. The autonomous government issued an edict reorganizing the schools in 1898, but their actual condition remained much as it was throughout the revolution at that time until a year after the American occupation, though there were said to be about 200 schools with 4000 pupils throughout the whole island.

On Dec. 6, 1899, the American Military Governor issued an order reorganizing the elementary and secondary school system of the island. It provided that there should be a board of education in each municipality, with the mayor as president, who should appoint the other members, and that there should be one public school for boys and one for girls in every town of 500 inhabitants, the number increasing with the size of the town. In smaller towns "incomplete" schools were to be established. It also provided for compulsory attendance, for the payment of tuition, for the inspection and superintendence, for free textbooks, and other details. The course of study was prescribed by the superintendent of schools. By March, 1900, there were 3099 schools, with 3500 teachers and 130,000 pupils. In the fall of 1901 there were 250,000 pupils, with almost 4000 teachers. Most of these children were in the first three grades, though a very small number were far enough advanced for the work of the fourth and fifth grades. This fact indicates the deficient conditions existing before 1900, for the age of the pupils is no indication of his stage of advancement.

One important phase of the American influence was the improvement of the teaching body. Summer normal schools were founded, which for two years furnished instruction to about 4000 teachers for a period of six weeks. During 1900 more than 1400 Cuban teachers attended the summer session of Harvard Uni-

versity, special provision having been made by that institution for their maintenance and instruction. Recognizing that permanent improvement must come from constant contact with advanced sources outside the island, the Cuban government is now supporting 60 women teachers at the State Normal School at New Paltz, N. Y., with the understanding that these teachers are to continue their services in the public schools for a term of years upon their return. With a similar motive the Cuban Educational Society, receiving its support from many prominent public officials and business and professional men of the United States, maintains some 40 or 50 youths in American colleges, with the expectation that they will return to advance the educational interests of the island. In similar ways more than 1500 Cuban and Porto Rican boys are now being educated in the United States, all under obligation to return to their homes on completing their schooling. Another important phase of the work is the supply of school material and school buildings. There was not one building on the island at the American intervention that had been constructed for or was used for public school purposes. There was little or no school furniture, and the books were of the most antiquated character. The American administration devoted a great deal of effort and more than \$400,000 to secure inhabitable school buildings. More than 100,000 school desks and other appliances in proportion were purchased and distributed throughout the island. Textbooks of modern standards were prepared and published by order of the education department of the government and supplied for the first four grades throughout the island. The changes thus made have had a marked effect upon the illiteracy of the population; and an educational system, modern in spirit and method and almost universal in the opportunities it offers, was thus turned over to the Cuban people when they took charge of their own government.

Two conditions are apt to interfere to some extent with any great immediate development or even the maintenance of these standards. In the first place, all the American administrative functionaries, save one, have been withdrawn, and political influence is apt to interfere to some extent. In the second place, the American administration devoted a larger proportion of the revenues of the government than the native direction possibly can; and the necessities for school expenditures are apt to increase more rapidly than the general wealth of the island. The military order which introduced the American system has been adopted as a precedent, and its chief features have been embodied in a school law of 1909. New types of schools have been added; new subjects (manual training, physical exercises, lace work, sewing, drawing, etc.) have been introduced; and more attention has been given to the teaching of English, the training of teachers, and instruction in agriculture. In 1912 there were 3916 schools, taught by 4055 teachers; there were 234,625 pupils enrolled, with an average attendance of 105,774. The appropriations for 1909 were \$4,275,794. For the fuller treatment of the educational status of all these islands, consult *Report of the United States Commissioner of Education*, 1899-99 and the following years. Consult also *Special Report on Educational Subjects*, vols. iv. and v, issued by the British Board of Education (Lon-

don, 1901). See CUBA; HAWAII; PHILIPPINES; PORTO RICO.

EDUCATION, COMMERCIAL. Recent experience and discussion are giving to commercial education a meaning as exact as are the terms "classical" and "technical" when applied to schemes of instruction. Confusion has arisen in dealing with this subject from the failure to distinguish between two different but perfectly legitimate senses in which the words are used. Commercial education may mean general education along modern lines, with a minimum of technical instruction, and, at the most, fairly preparing students for an intelligent apprenticeship in business pursuits. In this sense commercial schools are to the business world what preparatory trade schools are to the industrial world. Public commercial high schools, as they are being established in the United States, are, in the main, of this kind. Such training conforms to the European use of the term in that they give "a general education of such a nature as shall best fit youths for commercial pursuits." In another sense commercial education is applied to the training given in technical schools corresponding to trade schools or schools of technology. Such institutions give a maximum of technical instruction; they are made familiar by the American business college, but are further represented by higher schools and universities of commerce in both this country and Europe. The latter schools build at least on the general education of the secondary school. Higher commercial education has probably been best defined by the authorities of the London School of Economics and Political Science; it is that "which stands in the same relation to the life and calling of the manufacturer, the merchant, and other men of business as the medical schools of the universities to that of the physician—a system, that is, which provides a scientific training in the structure and organization of modern industry and commerce, and the general causes and criteria of prosperity."

Commercial Education in Europe. Germany may well be termed the home of commercial education. Special instruction along commercial lines was provided in Saxony in the eighteenth century. Well-organized commercial schools became a feature of German education in the nineteenth century; in 1898 a higher school of commerce was established at Leipzig—an example soon followed by other establishments in Cologne, Frankfurt, and Berlin. The Superior School of Commerce at Paris was founded in 1820 and continued to have a precarious existence under private management until 1869, when it was taken in charge by the Paris Chamber of Commerce. Commercial academies and schools have long been established in several other continental cities, among them being Vienna, Venice, and Antwerp. England has provided for higher commercial instruction at the London School of Economics and Political Science at the universities of Manchester, Liverpool, Leeds, Birmingham, and Belfast, while it has recently been proposed to make provision for the subject at Oxford. Both England and the continental countries have established schools that give commercial work of an elementary and rather technical character.

Commercial schools in Europe are of three types: 1. Higher, e.g. at Leipzig, Frankfurt, Cologne, Berlin, Paris, Lyons, Antwerp, Lon-

don, etc. Colleges and universities of commerce now being established in the United States correspond fairly to these schools. 2. Middle schools, academies, and the like, having usually a scheme of studies for three years, though some have four-year and others only two-year courses. These schools take students at about the ages at which they enter American high schools and give them an education more technical than is furnished in our high schools of commerce. 3. Some form of day or evening continuation school for those who are already serving apprenticeships in business pursuits. Chambers of commerce and other organizations of business men have in some cases assumed entire charge of commercial schools in Europe; in other cases the control has been by public or private authority alone; but a more common procedure is for business men to exercise some influence by serving on boards of control, supervising examinations, meeting deficits, etc. There are in addition, especially in Great Britain, numerous commercial and business colleges established as private ventures.

Commercial Education in the United States. The first clearly defined form of commercial instruction in America was that of the business college, which took their rise a little before the middle of the nineteenth century. Early in the eighties the Wharton School of Finance and Economy was established in the University of Pennsylvania (q.v.), and about the same time public high schools began to give work similar to that of the earlier business-college instruction. From this time the development of commercial education has been rapid. At present the universities of Pennsylvania and Wisconsin offer a full four-year college of commerce course, on the completion of which a baccalaureate degree is conferred. Since 1900 numerous other universities and colleges have established courses or departments for the scientific study of commerce. Among these may be mentioned Dartmouth (Amos Tuck School), New York University, the University of Chicago, the state universities of California, Illinois, and Michigan, Harvard University, the University of Vermont, and Tufts College. In some of these institutions the study of commerce forms part of the work of the college of liberal arts; in others a special four-year course, leading to a degree in commerce, is offered; while in others the subject is offered as a graduate professional course (Amos Tuck School at Dartmouth and the Harvard School of Business Administration). Some of these departments, e.g. Pennsylvania, have organized evening courses in commerce.

The growth of secondary schools of commerce has been more rapid than that of the colleges. Independent high schools devoted to commercial education are now in existence in New York, Chicago, Philadelphia, Washington, Pittsburgh, and other cities, while commercial departments and elective commercial studies are well-nigh universal in high schools of the country. The private business colleges are as well patronized as ever, and hundreds of thousands of young people are at present receiving a commercial education in the United States. Columbia University offers evening courses in commerce and finance, leading after three years to a certificate in commerce and preparing for the State examination for the certificate of Certified Public Accountant. It is also proposed to introduce

special courses in the College of the City of New York.

Associations and Journals. For nearly ten years the Business Education Section has been conducted as one of the departments of the National Education Association. Sessions are held annually in connection with National Association meetings, and the proceedings are printed in the association's report. Many other associations are active in this country, the best known of them being the National Federation of Commercial Teachers and the Eastern Commercial Teachers' Association. In England there is the Yorkshire Association for the Promotion of Commercial Education, and in Germany the Deutscher Verband für das kaufmännische Unterrichtswesen. Most important, perhaps, of all the societies is the International Association for the Advancement of Commercial Education. Among special journals are the *Zeitschrift für das gesamte kaufmännische Unterrichtswesen*, published by Teubner, in Leipzig, and the *Practical Educator*, published in Columbus, Ohio.

EDUCATION, COMMISSIONER OF. The chief officer of the Bureau of Education, at Washington. He is appointed by the President and Senate, and his duties are "to collect such statistics and facts as shall show the condition and progress of education in the several States and Territories"; to diffuse such "information respecting the organization and management of schools and school systems and methods of teaching as shall aid the people in the maintenance of efficient school systems and otherwise promote the cause of education"; and also "to present annually to Congress a report embodying the result of his investigations and labors, together with a statement of such facts and recommendations as will, in his judgment,

subserve the purpose for which the department is established." The office was established in March, 1867. The incumbents have been Henry Barnard (1867-70), John Eaton (1870-86), Nathaniel H. R. Dawson (1886-89), William T. Harris (1889-1906), Elmer E. Brown (1906-11), Philander P. Claxton (1911-).

EDUCATION ASSOCIATION, NATIONAL. A society of teachers and educators organized as the National Teachers' Association at Philadelphia, Pa., in 1857, and incorporated under its present name in the District of Columbia in 1886. The aid which associated teachers might render to the progress of education was recognized in the United States early in the nineteenth century, and a number of such societies were formed, though of somewhat limited scope. Perhaps the best known of these, the American Institute of Instruction, organized in 1830, confined its work to New England; a similar society in the West, the Western College of Teachers, was organized in Ohio in 1831; the American Association for the Advancement of Education was founded at Philadelphia in 1849, and there were, besides, numerous State educational societies. In 1856, however, a call was issued by the presidents of 12 of the State societies for a general association of national extent to "advance the dignity, respectability, and usefulness" of the teaching profession and to develop educational science "by distributing among all the accumulated experiences of all." The society thus initiated grew slowly and did not gather large effectiveness until its work began to be specialized in 1870. In that year combination was made with the American Normal Association and the National Superintendents' Association, and departments were instituted of higher and elementary instruction. Other sections were then rapidly inaugurated, so that the association at present includes the National Council, an advisory body, and 19 departments devoted to the special problems of method, organization, and the courses of study in nearly every type and grade of educational work. At their annual meetings held in different parts of the country the society gives large space to specialized and concrete discussions in the several departments. These proceedings, together with those of the society as a whole, published in the *Annual Reports*, constitute the most important body of pedagogical literature in the country. In 1892 a committee of 10 was appointed to report upon the curricula of secondary schools. This report, insisting upon greater intensity and coherence in school work and upon the more intimate correlation of studies, exercised wide influence, and its conclusions were very generally adopted. Other reports exercising an influence hardly less wide were those of the committees on elementary schools (1895), on rural schools (1897), on college entrance requirements (1899), on normal schools (1899), on public libraries and public schools (1899), and on teachers' salaries (1913 and 1914). The active membership of the society is some 10,000, but the annual meetings are usually attended by more than that number, the larger proportion being associate members.

The meeting and exchange of opinions of teachers from all sections of the country has contributed largely towards unifying educational procedure and in developing an approximately even system of educational theory. Several of the leading educators of the country have taken an active interest in the association's welfare. Among these may be especially mentioned Nicholas Murray Butler (q.v.) and William T. Harris (q.v.). Consult: *History of the National Education Association of the United States* (Washington, D. C., 1892); the reports of the Committee of Fifteen, the Committee of Ten etc.; the *Proceedings of the Department of Superintendence of the National Council*; the annual volumes of the *Proceedings of the National Education Association* (Washington, D. C.).

EDWARD, or EADWARD (?-924). A king of the English, known as the Elder. He was the son of Alfred the Great and was chosen by the witan to succeed his father, probably in October, 901, having previously distinguished himself in the wars with the Danes. His cousin Ethelwold, who disputed Edward's right of succession, was killed in battle in 905. After 20 years of fighting Edward subdued the north as far as the Humber and was recognized as overlord by all the other kings in the island. Consult: Green, *The Conquest of England* (London and New York, 1883); Hodgkin, *History of England, from the Earliest Times to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EDWARD, or EADWARD (c.963-978). A king of the English, known as the Martyr. He succeeded his father, Edgar, in 975, at the age of about 12. His succession was disputed in behalf of his half brother, Ethelred, a child of seven; but the powerful influence of St. Dunstan decided the contest in favor of Edward. He was assassinated in 978, at the instigation probably of his stepmother, Ælfthryth, who was disappointed at her failure to gain the crown for her son Ethelred. Consult: Green, *The Conquest of England* (London and New York, 1883); Hodgkin, *History of England, from the Earliest Times to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EDWARD, or EADWARD (c.1004-66). King of the English from 1042 to 1066, known as the CONFESSOR. He was the elder son of Ethelred the Unready and was born at Islip, in Oxfordshire, about the year 1004. On the death of Edward's father, in 1016, followed soon after by the death of Edmund Ironside (q.v.), Canute, the Dane, obtained possession of the throne and in the following year married Emma, the mother of Edward, by whom he had a son named Hardicanute, or Marthanut. Until the death of Canute, in 1035, Edward lived in Normandy. Then he made an ineffectual attempt to establish his authority in England; but his mother, Emma, sided with her younger son, Hardicanute, who on the death of Harold, his half brother, in 1040, became sole ruler of the English kingdom. Hardicanute probably invited Edward to England, where he was honorably received. On the death of Hardicanute, in 1042, Edward was elected King. The person chiefly instrumental in bringing about this result was Earl Godwine, whose only daughter Edith, or Eadgith, became Edward's wife in 1045. For a number of years the reins of

to France were practically in the hands of Edward and his sons, who were powerful enough at times openly to impose their will upon the King. Edward himself showed little inclination for the affairs of government, and his mild disposition and ascetic temperament made him as little sensible to the attractions of worldly power as to the charms of his beautiful wife. His life was passed for the greater part in holy works, his most lasting monument being Westminster Abbey, which he caused to be built. He died Jan. 5, 1066. The honor of canonization and the title of Confessor were conferred on him in 1161 by Pope Alexander III. The whole of his reign is simply the record of the growth of the Norman, or court, party and its struggle with the National, or baronial, party—for an account of which, see ARBOLD. Wars with the Welsh in 1057 and 1063 and with the Northumbrians in 1065 were short and successful. Consult Freeman, *The Norman Conquest*, vol. ii (Oxford, 1877), this giving the fullest and best account of Edward's reign; Hodgkin, *History of England, to 1066* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910). See ANGLO-SAXONS.

EDWARD I (1239-1307). King of England from 1272 to 1307. He was the eldest son of Henry III by his wife, Eleanor of Provence, and was born at Westminster, June 17-18, 1239. In 1252 his father bestowed upon him the lordship of Gascony, and in 1254, on his marriage to Eleanor of Castile, he received, as an additional gift from his father, Ireland and Wales and the towns of Bristol, Stamford, and Grantham. In his early years he was surrounded by foreigners and was guilty of many injudicious and some cruel actions. The misgovernment of Wales by his officials led to a revolt in which the Welsh allied themselves with the Scotch. A dangerous war followed, which brought to a head the general discontent which prevailed in England over the bestowal of great offices of state upon foreigners and the King's subserviency to the see of Rome. The Provisions of Oxford (q.v.), greatly limiting the power of the crown, were drawn up by Parliament, and both Edward and his father were compelled to swear to observe them. Edward, however, used the opportunity afforded by the divisions among the nobility to place himself at the head of the party of the lesser nobles, who were opposed to the great barons. War broke out in 1263. There were many indecisive engagements; after the battle of Lewes (1264) Edward was made a hostage for his father's conduct and was treated as a prisoner. He escaped in May, 1265, and on August 4 won a complete victory over his opponents at Evesham. The resistance of the barons, nevertheless, dragged on until July, 1267. The defeated were treated with great moderation, and Edward showed by prudence and wisdom that he had outgrown the faults of his youth. In 1268 he assumed the Crusader's cross, and in 1270 set out to join Louis IX of France on his crusade. Louis died on the coast of Africa, and the French Crusaders made peace with the Mohammedans: but Edward persisted in the enterprise and landed at Acre in 1271. Nothing, however, of any consequence was achieved, and in the following year he set out on his return to England. In Sicily he heard of his father's death (1272), but did not hurry home. In 1273 he proceeded

to France and did homage to Philip III for his French possessions. He arrived in England, Aug. 2, 1274, and, with his Queen, Eleanor, was crowned at Westminster on August 19. His first military expedition after his accession to the throne was directed against the Welsh. After an intermittent contest of nearly 10 years—in the course of which the famous Prince Llewellyn (q.v.) was slain at Radnor, Dec. 11, 1282—Wales was finally subdued and incorporated with England.

Edward's great ambition was to gain possession of Scotland. The death, in 1290, of Margaret, the Maid of Norway, granddaughter of Alexander III, who was to have been married to Edward's son, seemed for a time to have frustrated his design; but the selfishness of the competitors for the Scottish crown induced them to acknowledge Edward as Lord Paramount of Scotland, each hoping that he would thereby secure the English monarch's support. John Baliol and Robert Bruce were also foolish enough to make him umpire between them; or perhaps it would be more correct to say they were not powerful enough to refuse his arbitration. At Berwick, Nov. 17, 1292, Edward decided in favor of John Baliol, who took the oath of fealty to him, and Edward did homage to the English King for his crown. The patriotism and pride of the Scots took fire at such humiliation, and in a short time Baliol was hurried by his subjects into a war with England. In 1296 Edward entered Scotland, devastating it with fire and sword. He penetrated as far north as Elgin, compelled Baliol to resign the throne, and governed the country by means of a board of regency. It was during this expedition that he carried off from the cathedral of Scone the celebrated stone on which the kings of Scotland used to be crowned and which is now in Westminster Abbey. A second rising took place in Scotland in the following summer. The leader on this occasion was William Wallace. He was completely successful for a time, chiefly, it is supposed, on account of the absence of Edward. In the spring of 1298, however, that sovereign again made his appearance in Scotland and gave battle to Wallace at Falkirk on July 22. Partly through treachery and partly, no doubt, through the superior generalship of Edward, who is considered to have been the first military commander of his time in Europe, the Scottish forces were entirely defeated. The next five years were spent by the English in reducing the country to obedience—with very imperfect success, however. In the summer of 1301 Edward led a third army into Scotland, but soon made a truce; in 1303 he once more spread havoc and ruin to the shores of the Moray Firth. The last castle that held out against him was Stirling, which did not yield until July 24, 1304. Some time after this Wallace either fell into his hands or was betrayed, and on Aug. 23, 1305, was executed. In the spring of 1306 Robert Bruce, Earl of Carrick, grandson of the chief rival of Baliol, suddenly entered the English court, unfurled once more the banner of Scottish independence, and on March 27 of that year was crowned at Scone. An English army under the Earl of Pembroke was immediately dispatched to Scotland, and at the close of the year the King himself set out to chastise Bruce. But Edward only lived to reach Burgh-on-Sands, a village beyond Carlisle, where he expired July

7, 1307, "in sight of the country," says Lord Hailes, "which he had devoted to destruction."

As a ruler, Edward is entitled to the highest praise. Immense progress was made during his reign in the establishment and improvement of law and order throughout the land, in the reformation of civil abuses, and in the restriction of the ecclesiastical power. He has been called the English Justinian, and both Hale and Blackstone affirm that "the very scheme and model of the administration of common justice between man and man was entirely settled by this King." Ireland and Wales participated in the benefits of English law. It was during Edward's reign, too, that the representation of the Commons of England first became regular; but the greatest advantage obtained by the declaration that the right of levying taxes resided in Parliament. In general, it may be said that Edward ruled in harmony with the ideas and desires of the best heads among his nobles and burgesses; and though touchy on the question of his prerogative, like every Plantagenet, and cruel in his treatment of the Jews, he must be regarded, on the whole, as one of the most enlightened and successful monarchs of his age. EDWARD II. A tragedy by Christopher Marlowe (about 1590), published 1598.

EDWARD II (1284-1327). King of England from 1307 to 1327. He was the son of Edward I and was born at Carnarvon, April 25, 1284. In 1301 he was created Prince of Wales, being the first heir apparent to the English throne who bore that title. He accompanied his father on his expeditions into Scotland, but after the death of the latter he abandoned the personal conduct of the war and returned to England. At home Edward's mode of life was contemptible. While still a youth he had conceived an extraordinary admiration and fondness for a witty, clever, but dissolute courtier called Piers de Gaveston, the son of a Gascon knight. After Edward became King there was no limit to the honors heaped on the favorite. When the King went to France in the beginning of 1308, to conclude a marriage with Isabella, daughter of Philip the Fair, Gaveston was left as guardian of the kingdom. The nobles were indignant and demanded his banishment. Twice Gaveston was forced to leave England, but as often he was recalled by the weak monarch, whose love for him amounted to sheer infatuation. At last the nobles rose in arms, besieged Gaveston in Scarborough Castle, and, having forced him to surrender, hanged him June 19, 1312. Two years after this Edward invaded Scotland at the head of a great army, amounting, according to some historians, to 100,000 men. At Bannockburn, on June 24, 1314, he was encountered by Robert Bruce (q.v.) and defeated with immense slaughter. Finally, in 1319, after numerous petty successes on the part of the Scots, Edward concluded a truce with them for two years. Once more he fell under the influence of unscrupulous favorites, the persons selected

on this occasion being the two Despensers. Once more the nobles rebelled and both Hugh le Despenser and his father were banished in July, 1321; but some months after they were recalled by Edward. Many of the rebellious nobles, among others the Earl of Lancaster, were beheaded in the following year. Immediately thereafter Edward invaded Scotland for the last time, but, having achieved no success, concluded a truce with that country for 13 years and returned to England. A dispute now arose between him and Charles IV of France, brother of his wife, Isabella, in regard to the territories which the English King held in that country. When Charles seized the lands in question, Edward sent over Isabella to remonstrate, and, if possible, to effect an amicable arrangement between them. Isabella, it would appear, despised her husband and disliked the Despensers. Meeting at the French court many English nobles who had left their country to avoid the enmity of the favorites, she was easily induced to make common cause with them against her husband and the Despensers. She obtained possession of the young Prince of Wales (afterward Edward III) and landed at Orwell, in Suffolk, Sept. 24, 1326. The Queen and the banished nobles were joined by all the influential persons in the country, fled, but was taken prisoner. The Despensers, father and son, were executed, and the monarch himself, after being formally deposed by Parliament, Jan. 20, 1327, was murdered in Berkeley Castle on September 21 of the same year. He left two sons and two daughters. Consult: Stubbs, *Constitutional History of England*, vol. ii (Oxford, 1896); Tout, *Political History of England, 1216-1377* (London, 1905); Vickers, *History of England, 1272-1485* (ib., 1912). See BANNOCKBURN; DESPENSER; GAVESTON.

EDWARD III (1312-77). King of England from 1327 to 1377. He was the son of Edward II and was born at Windsor, Nov. 13, 1312. He was chosen King by Parliament on Jan. 14, 1327, six days before a formal resignation was extorted from the unhappy Edward II (q.v.). During his minority the country was governed nominally by a council, but in reality by the Queen mother, Isabella, and her lover, Mortimer. On Jan. 24, 1328, Edward married Philippa, daughter of the Earl of Hainault. Two years later, resolving to take the power in his own hands, he seized Mortimer, put him to death, Nov. 29, 1330, and banished his mother to her house at Rising, where she was kept until her death. In 1333 Edward, claiming that the Scots had violated the truce between the two countries, invaded Scotland. A bloody battle was fought at Halidon Hill, near Berwick, July 20, 1333, in which the Scots were completely defeated. Edward Balliol was restored to the throne and surrendered part of his kingdom to Edward. In the course of three years Edward thrice invaded Scotland; but though he laid the country waste and brought armies with him that effectually crushed all opposition, he could not break the spirit of the people. The scene of Edward's great exploits, however, was France. As all the sons of Philip the Fair had died without male heirs, Isabella, his daughter, claimed the kingdom of France for her son Edward. Most French authorities, however, held that the crown could descend only in the male line, and accordingly Philip VI (q.v.), the nephew of Philip the Fair, was recognized

as King. For several years hostilities were averted: but when France, in 1337, interfered to aid Scotland, Edward declared war against France. This was the beginning of the Hundred Years' War. The early conflicts were of little importance; but in 1346 Edward, accompanied by his eldest son, the Black Prince, made a new invasion of France, conquered a great part of Normandy, marched to within a few miles of Paris, and on August 26 of that year inflicted a tremendous defeat on the French at Crécy (q.v.). Here Edward, the Black Prince, though only 16, exhibited the courage and prowess of a veteran. After some further successes, such as the reduction of Calais, a truce was concluded between the two nations for nine months. Meanwhile the Scots had sustained a severe defeat at Neville's Cross, near Durham, Oct. 17, 1346, their King, David II, being taken prisoner. On Sept. 19, 1356, the Black Prince obtained a brilliant victory at Poitiers, King John of France falling into his hands. The Scottish monarch was released for a ransom of £100,000 in 1357, and King John for a ransom of 3,000,000 crowns in 1360. On Nov. 27, 1363, David, King of Scotland, entered into a secret agreement with Edward, in virtue of which his kingdom, if he died without male issue, was to pass to the English sovereign. Meanwhile the Black Prince, who had married Joanna, daughter of the Earl of Kent, had received from his father Aquitaine and Gascony and ruled there for some time prosperously. War with France broke out again in 1369; the English were unsuccessful, and in 1375 a truce was concluded on account of the exhaustion of both parties. Edward waged war no more. In spite of his brilliant victories, and in spite of the valor of his son, he failed to achieve success. Neither in Scotland nor in France did he realize his ambitions. Affairs at home were no less unsatisfactory during the last years of his life. He quarreled with his parliaments, and the Black Prince sided with the opposition. The aged King fell completely under the control of his mistress, Alice Perrers, and of a small coterie of unscrupulous courtiers, headed by the King's son, John of Gaunt, Duke of Lancaster. Edward died on June 21, 1377. By his wife, Philippa, he had seven sons and five daughters, seven of whom died young. Edward's reign acted the part of a knight-errant, that of a king. He was hard-hearted and selfish and never won the love of his people. He died deserted by all. His private life was immoral, and his public actions governed only by his own interests. Among the laws of Edward's reign were several which attacked papal claims to religious taxes. Consult: Longman, *Life and Times of Edward III* (London, 1869); Stubbs, *Constitutional History of England*, vol. ii (Oxford, 1896); Green, *History of the English People*, vol. i (London, and New York, 1878); Mackinnon, *History of Edward III* (London, 1900); Tout, *Political History of England, 1216-1377* (ib., 1905); Vickers, *History of England, 1272-1485* (ib., 1912). See HUNDRED YEARS' WAR; SCOTLAND.

EDWARD IV (1442-83). King of England from 1461 to 1483. He was the son of Richard, Duke of York, and was born at Rouen in 1442. His title by inheritance was that of Earl of March. After the death of his father, in the battle of Wakefield, Dec. 30, 1460, Edward

became the head of the Yorkist party and as such speedily reestablished the fortunes of his house. After routing the Royal or Lancastrian forces, under the earls of Pembroke and Ormond, at Mortimer's Cross, near Hereford, Feb. 2, 1461, Edward marched towards London, which he entered on February 26. He immediately laid his claim to the crown before Parliament, which admitted its validity, and on March 4 he ascended the throne as Edward IV amid the acclamations of the citizens of London, with whom he was a great favorite. His first victory as King over the Lancastrians was obtained at Towton, in Yorkshire, on March 29, 1461. This was followed by minor successes, till finally, in May, 1464, by the victories of Lord Montague, the Lancastrians were completely crushed. On May 1, 1464, Edward married Elizabeth Woodville, widow of Sir John Grey. This marriage gave great offense to the Earl of Warwick, by far the most powerful of Edward's adherents, who was at that time engaged in negotiating a marriage between Edward and the sister-in-law of Louis XI of France. The favors showered upon the Queen's relatives caused great discontent. In 1469 Warwick openly declared against Edward, joined Queen Margaret, the wife of the helpless Henry VI and the intrepid leader of the Lancastrians, and finally compelled Edward to flee the country. Henry VI was released from the Tower, where he had been a prisoner for six years, and was once more invested with the royal authority. But in the spring of 1471 Edward landed at the Humber, proceeded to London, seized the person of Henry, and was again hailed King by the inhabitants. Warwick now gathered an army and hurried to encounter him. The two met at Barnet, where Warwick was defeated and slain, April 14, 1471. On May 4 Edward routed the Lancastrians at Tewkesbury, capturing Queen Margaret. Her son, Prince Edward, was either slain in battle or murdered the day after the fight. Henry VI died May 21, 1471, not without suspicion of murder. Though the later years of Edward's reign were peaceful and marked by few political incidents of any moment, the period was one of great importance in the development of the English constitution. Easygoing as he was and fond of pleasure, the King steadily pursued his aim of aggrandizing the crown at the expense of Parliament, and by a policy of silent but aggressive assertion he succeeded in laying the foundations for the absolute monarchy of the Tudors. Edward was brave and debonair, as his immense popularity shows, but he was disolute in the extreme. By his wife he had 10 children, of whom seven outlived him. It was during his reign that printing and silk manufactures were introduced into England. In law few notable changes occurred, but the practice of indirect pleading dates from this period, which is also illustrious for the names of distinguished legists, such as Littleton and Fortescue. Consult: Ramsay, *Lancaster and York* (2 vols., Oxford, 1892); Oman, *Political History of England*, vol. iv (London, 1906); Vickers, *History of England, 1272-1485* (ib., 1912); Green, *History of the English People* (London and New York, 1878). See Henry VI; ROSES, WAR OF THE; WARWICK, RICHARD NEVILLE, EARL OF.

EDWARD V (1470-83). King of England. The son of Edward IV, he was born in the Westminster Sanctuary, Nov. 4, 1470. When

his father died, he was 13 years old. He proceeded to London for his coronation, which had been appointed for May 14, 1483, but was removed from the care of his maternal relatives by his paternal uncle, Richard, Duke of Gloucester, who in the same month had himself proclaimed Protector of the Kingdom and confined Edward and his younger brother, the Duke of York, in the Tower. The rumor of their death spread, when a movement originated for their liberation, but was discredited, popular opinion maintaining that they had been exiled. Twenty years later it transpired that Brackenbury, Constable of the Tower, refused to slay the princes at Richard's command, and Sir James Tyrrel, with two servants, gained admittance to their chamber while they were asleep, smothered them with pillows, and buried them at the foot of a staircase. The skeletons found at the foot of a staircase in the White Tower in the reign of Charles II and buried at his command in Westminster Abbey are considered to have been those of the young princes.

EDWARD VI (1537-53). King of England from 1547 to 1553. The son of Henry VIII by his third wife, Jane Seymour. Edward was born at Hampton Court, Oct. 12, 1537. He succeeded to the throne after his father's death, Jan. 28, 1547, his uncle, Edward Seymour, Earl of Hertford, being chosen Protector and created Duke of Somerset. Edward received a careful education and was a studious, religious, and precocious youth; but he was too young to exercise any personal influence on the important events of his reign. His religious convictions, however, were shared by the Protector, who favored the principles of the Reformation, and during his rule great strides were made towards the establishment of Protestantism in England. The images were removed from the churches; the laity were allowed the cup at the ceremony of the Lord's Supper; Henry's famous six articles (known as the Bloody Statute) were repealed; and a new service book, known as the First Prayer Book of Edward VI (see PRAYER BOOK, COMMON), was compiled by Cranmer and Ridley, assisted by 11 other divines, and ordered to be used. During the first year of the protectorate Seymour invaded Scotland, on account of the refusal of the Scottish government to fulfill the contract into which it had entered with Henry VIII that Mary, Queen of Scots, should marry Edward. At the battle of Pinkie, Sept. 10, 1547, the Scots were completely beaten; but Seymour, before he could inflict other damage, was required at home and returned to find that his brother, Lord Seymour, had been intriguing against him. Somerset had him arrested, tried, and condemned for treason, and on March 30, 1549, he was beheaded on Tower Hill. In the summer of the same year the Protector quelled an insurrection of the populace headed by one Kett, a tanner; but a more dangerous adversary appeared in John Dudley, Earl of Warwick, whose party, by insinuations against Somerset, excited the nation against him and compelled the King to sign his deposition. In October, 1551, Somerset was placed in the Tower; and on December 1 he was tried before the House of Lords for treason, condemned, and executed, Jan. 22, 1552. Before Somerset's execution Dudley had been created Duke of Northumberland. He was (judging from his dying declaration) a Catholic, but took no action to reestablish the old religion. His great aim was

to secure the succession to the throne of England for his family. With this view he married his son, Lord Guildford Dudley, to Lady Jane Grey, daughter of the Duchess of Suffolk, to whom Henry VIII had willed the crown in default of issue by Edward, Mary, or Elizabeth. Northumberland worked upon the consumptive and dying Edward to exclude Mary and Elizabeth on the ground of illegitimacy and to nominate Lady Jane Grey as his successor. Edward consented, and a document settling the succession on this lady was drawn up in June, 1553. The King lived only a few weeks after, and died July 6. Edward's educational accomplishments were somewhat discounted by shrewdness and a hardness of character, which were exemplified by marked callousness when signing the death warrants of Seymour and Somerset. Edward VI restored many of the grammar schools suppressed by Henry VIII. These schools are still known as King Edward's schools. Consult: Nichol, *Literary Remains of Edward VI* (2 vols., London, 1857); Gasquet and Bishop, *Edward VI and the Book of Common Prayer* (ib., 1891); Markham, *Edward VI* (ib., 1907); Fisher, *History of England, 1485-1547* (ib., 1906); Pollard, *History of England, 1547-1603* (ib., 1910); Innes, *England under the Tudors* (ib., 1905).

EDWARD VII (1841-1910). King of the United Kingdom of Great Britain and Ireland, and of the various Dominions beyond the Seas, Emperor of India. The second child and eldest son of Queen Victoria and the Prince Consort, Albert (q.v.). He was born in Buckingham Palace, London, on Nov. 9, 1841, and was christened Albert Edward. He succeeded his mother on Jan. 22, 1901. At his birth he was created Prince of Wales, and by virtue of that dignity he became also Knight of the Garter. As heir apparent to the British throne, he succeeded to the title of Duke of Cornwall and its emoluments. As heir to the crown of Scotland, he became Great Steward of Scotland, Duke of Rothesay, Earl of Carrick, Baron Renfrew, and Lord of the Isles. On Sept. 10, 1849, he was created Earl of Dublin, a title conferred on him and his heirs in perpetuity. Additional titles and commands borne by him were: Duke of Saxony, colonel of the Tenth Hussars, colonel in chief of the Rifle Brigade, field marshal of the British army (1875), also of the German army (1883). He received an elaborate and carefully planned education under four private tutors and subsequently under Baron Stockmar and Charles Kingsley. He spent a session at Edinburgh University, a year at Christ Church, Oxford, and four terms at Cambridge. In 1860 he traveled as Baron Renfrew through Canada and the United States. In June, 1861, he joined the army at the Curragh Camp, Ireland. The next year, during the period of mourning which followed the death of his father, he made a tour of the Orient, accompanied by Dean Stanley of Westminster, and visited Jerusalem and other places of biblical interest.

In February, 1863, his public life was formally begun, when, as heir to the throne, he took his seat in the House of Lords, and on March 10 of the same year he married Princess Alexandra Caroline Mary Charlotte Louisa Julia, eldest daughter of King Christian IX of Denmark, born Dec. 1, 1844. They had six children: 1. Prince Albert Victor Christian Edward, Duke of Clarence and Avondale, born Jan. 8, 1864; died Jan.

14, 1892. 2. Prince George Frederick Ernest Albert, Prince of Wales, formerly Duke of York, born June 3, 1865; married Princess May of Teck, July 6, 1893. 3. Princess Louisa Victoria Alexandra Dagmar, born Feb. 20, 1867; married, July 27, 1889, to the Earl, afterward Duke, of Fife. 4. Princess Victoria Alexandra Olga Mary, born July 6, 1868. 5. Princess Maude Charlotte Mary Victoria, born Nov. 26, 1869; married, July 22, 1896, to Prince Charles of Denmark. 6. Prince Alexander John Charles Albert, born April 6, 1871, who died the next day.

In 1868-69 the Prince with the Princess of Wales visited Ireland and the Continent, extending their tour to include Egypt. In 1871, an attack of typhoid fever threatened to endanger his life, his recovery was celebrated throughout the Empire. His popularity was seen in his hospitality and the loyalty shown him in 1875-76 during his tour through India. The years of his mother's widowhood and virtual retirement were for the Prince a long period of preparation for his duties as King. Upon him fell not only the leadership of British society, but especially the arduous duties of representing the crown at innumerable public functions. The tact with which he performed these duties enhanced his popularity at home, and his influence abroad. Among his activities during these years should be mentioned his large responsibility for the Queen's notable Jubilees of 1887 and 1897. As a patron of art and science, the Prince was largely instrumental in the promotion of the Royal College of Music and the Imperial Institute. He patronized the Welsh Eisteddfod and in 1896 became first chancellor of the University of Wales. He served as Grand Master of English Freemasons and was a bencher and officer of the Middle Temple. He showed active interest also in exhibitions in agriculture, the housing of the poor, and charitable institutions. In 1897 he established a hospital fund which he maintained as King. With careful regard for British jealousy of royal interference in politics he avoided all appearance of partisan preferences. However, he maintained friendly and courteous relations with all public men and thus was able at several critical times by his visits to Gladstone, Bright, and other Liberal leaders to counteract the impression made upon public opinion by the Queen's preferences for Conservative ministers.

His London residence was at Marlborough House, but at Sandringham, Norfolk, he lived as a typical English country gentleman, giving much care to the improvement of his estates and to the breeding of fine stock. He was, likewise, a keen sportsman, taking especial interest in yachting and horse racing. These interests largely offset in the popular mind other circumstances which, like his connection with the Tranby Croft baccarat case (1890), tended to compromise his private reputation.

When he became King upon the death of Queen Victoria, Jan. 22, 1901, he was, save William IV, the oldest ruler to receive the English crown since Egbert. One of the acts of the Parliament which met a few weeks after his accession was to amplify the royal title so as to embrace "all the British Dominions beyond the Seas." His coronation was set for June 26, 1902, and preparations had been perfected for its celebration with ceremonial pomp such as England had not witnessed in generations, when

a few days previous to the date set rumors of the King's illness were confirmed by the announcement that he was suffering from perityphlitis. The ceremonies were therefore postponed, and on June 24 an operation was performed which proved successful, and the coronation in the Abbey took place on August 9, although other festivities were deferred for several months.

The year following his coronation, and again in 1904, the King visited Ireland and held court at Dublin. He was received with popular enthusiasm because of his well-known interest in the welfare of his Irish subjects. By similar state visits to the Continent, which were usually returned by the sovereigns visited, he contributed greatly to the maintenance of European peace and won for himself a rôle for which he was happily fitted by his personality and aided by his extensive family connections with most of the European rulers. Among the most significant of these political visits were those with the German Emperor in 1904 and 1908, the meeting with the Czar at Reval in 1908, and the interchange of visits the same year with President Fallières of France. King Edward was also interested in the increasingly cordial relations with the United States. The results of these amicable relations may be seen in the British policy during the Russo-Japanese War, in the *entente* reached with France, and in the various arbitration treaties made by Great Britain during this reign.

At home the King maintained the popularity which he had earned as prince by his deep interest in philanthropic enterprises. He also instituted the Edward medal for deeds of heroism by civilians, and he founded the Order of Merit for distinction in war, science, and literature and the service of man. In the last months of his reign the measures of the Asquith ministry, especially the Land-Gift Bill, land taxes and the crisis with the House of Lords, caused the King much anxiety. His death came unexpectedly on May 6, 1910, from heart failure incident to a bronchial attack. After lying in state for three days at Westminster Hall the body of the King was taken, on May 20, to Windsor for burial. The funeral was notable for the number of foreign sovereigns and important public men who participated. It was a fitting testimony to the universal esteem with which King Edward was regarded. Consult: *The Private Life of King Edward VII* (New York, 1901); *Life of the King*, by "One of His Majesty's Servants" (London, 1901); Hopkins, *Life of King Edward VII* (Philadelphia, 1902); Holt-White, *The People's King* (New York, 1910); Watson, *King Edward VII as a Sportsman* (London, 1911); Legge, *King Edward in his True Colours* (ib., 1912). For a brief comprehensive account and a good bibliography, consult *The Dictionary of National Biography*, 2d supplement, vol. i (New York, 1912).

EDWARD, THE BLACK PRINCE (so named from the color of his armor) (1330-76). The eldest son of Edward III of England. He was created Duke of Cornwall in his seventh year and a year later, during the absence of his father, who was embarking on his war against France, was appointed nominal guardian of the kingdom. He held this office again in 1340 and 1342 and was created Prince of Wales in 1343. Three years later he accompanied his father to France and in the battle

of Crécy (q.v.) led the most gallant division of the army. He also shared the glory in the victories which followed. In 1355 he was given command of the chief army in the French War, landed at Bordeaux, and after several smaller successes gained, in 1356, the victory of Poitiers (q.v.), capturing the French King, John II, whom he carried captive to London in 1357. In 1361, during the short peace following King John's ransom, Edward married his cousin Joanna, the "fair maid of Kent," whose third husband he was, and, being created Prince of Aquitaine and Gascony in 1362, crossed over to his new possession, which he ruled successfully and peacefully for a time. Entering into an entangling alliance with Peter the Cruel, the deposed King of Castile, he found himself burdened with the expenses and losses of a profitless war, and for the excessive taxes laid upon his duchy was summoned to account by the French King as his liege lord. To this summons Edward replied haughtily, "We will come, with our helmet on our head and 60,000 men in our company." This led to a rupture between France and England. The French planned a double invasion of the English territory in France. The Duke of Anjou, commanding one expedition, besieged Limoges, which had been ceded to the English by the Treaty of Breigny and formed part of the Principality of Aquitaine. The city was surrendered by the treachery of its Bishop. The Black Prince, enraged by this act, after a siege of a month recaptured the city by assault (1370) and is said to have put to the sword 3000 of its inhabitants. This outburst of cruelty is the chief blot on the fame of the Prince, and it is only partially explained by his disordered health, which itself was perhaps due to the irritation of seeing the English power waning in France, in spite of all his victories. He was compelled by the advice of his physicians to return in 1371 to England, where, except for a short and unsuccessful expedition against France in 1372, he lingered in continually failing health for five years. In these years he saw the loss of Aquitaine, but he did good service to the country in opposing the corrupt and oppressive influences which surrounded the dotting Edward III, and by his help Parliament was able to pass acts in restraint of the dangerous ambition of John, Duke of Lancaster. He died, probably in June, 1376, and was buried in the cathedral of Canterbury, where part of his armor still hangs above his tomb. His second son occupied the throne in the following years as Richard II. Consult: Longman, *Life and Times of Edward III* (London, 1869); Mackinnon, *History of Edward III* (ib., 1900); Dunn-Pattison, *The Black Prince* (ib., 1910); Tout, *Political History of England, 1216-1377* (ib., 1905); Vickers, *History of England, 1272-1485* (ib., 1912).

EDWARD, THOMAS (1814-86). A Scottish zoölogist and collector, known as "the Banff naturalist." He was born at Gosport, Hampshire, and at 11 years of age he was apprenticed in Aberdeen to a shoemaker, whose trade he followed throughout his life, mainly near Banff. Before he was five years old he showed an almost passionate fondness for all sorts of birds and animals, and by 1845 he had collected some 2000 species of animals, which he was compelled to sell for about £20. He then set courageously at work to make another collection, at the same time recording his observations, which his friend, the Rev. James Smith,

sent to the *Zoölogist*, where the publication of his detailed and minute descriptions of the habits of birds and beasts attracted attention from the similarity of his methods and of his accounts to those of Audubon. He later turned his attention enthusiastically to marine zoölogy and discovered 20 new species of *crustacea* in the Moray Firth. In 1866 came the first recognition of the scientific value of his researches, in an election as an associate of the Linnæan Society of London. In 1876, through the influence of Charles Darwin and a biography of Edward, written by Samuel Smiles, he received an annual civil-list pension of £50. Consult Smiles, *Life of Thomas Edward* (London, 1876).

EDWARDES, SIR HERBERT BENJAMIN (1819-68). A British East Indian soldier and administrator. He was born at Prodesley, in Shropshire, was educated at King's College, London, and entered the Indian army as a cadet in the First Bengal Fusiliers in 1840. He won promotion rapidly and served on the staff of Sir Hugh Gough, the British commander in chief in the first Sikh War, in 1845-46. In 1847 he was made first assistant to Sir Henry Lawrence, the British resident at Lahore. In the summer of 1848 he suppressed an uprising in Mooltan and for his services received the thanks of both Houses of Parliament and was brevetted major. He wrote an account of the campaign, entitled *A Year on the Punjab Frontier in 1848-49*. During the Indian Mutiny in 1857 Edwardes rendered invaluable services by securing the neutrality of Afghanistan, thus enabling the troops to be withdrawn from the northwest border and used effectively in the relief of Delhi and Lucknow. He was offered the governorship of the Punjab in 1862, but refused it on account of failing health, which compelled his return to England. He died shortly after being promoted to the rank of major general. The town of Banu in the Punjab was renamed, in his honor, Edwardesabad.

EDWARDS, ALPHONSE and HENRI MILNE. See MILNE-EDWARDS.

EDWARDS, AMELIA ANN BLANDFORD (1831-92). An English novelist and Egyptologist, born in London, June 7, 1831. As a contributor to various magazines and newspapers, she gave early evidence of considerable literary ability. She first attracted attention as an author by *My Brother's Wife*, which appeared in 1855. This was followed in 1859 by *Hand and Glove*, and later by *Debenham's Vow* (1870), *In The Days of My Youth* (1872), and *Lord Brackenbury* (1880). Of all her novels *Debenham's Vow* and *Lord Brackenbury* were the most successful. In 1873 Miss Edwards visited Egypt and as a result of her trip became intensely interested in Egyptology. In 1877 she published an account of her own explorations on the Nile in a book entitled *A Thousand Miles up the Nile*. This she illustrated by sketches from her own hand. It was largely through her interest in the ruins of Egypt and a desire to preserve them that the Egyptian Exploration Fund came to be formed. In 1889-90 she lectured in the United States, and these lectures appeared in 1891 in book form under the title, *Pharaohs, Fellahs, and Explorers*. The last 10 years of her life were devoted to the study of Egyptology. In this field she contributed to the ninth edition of the *Encyclopædia Britannica*, to the American supplement of that work, and to the *Standard*

Dictionary. Her collection of Egyptian antiquities was bequeathed to University College, London.

EDWARDS, ARTHUR (1834-1901). An American clergyman and editor, born at Norwalk, Ohio. He graduated from Ohio Wesleyan University in 1858 and entered the Methodist ministry the same year, joining the Detroit conference. As chaplain of the First Michigan Infantry, he served in the Civil War until after the battle of Gettysburg; he was in 18 battles altogether and was offered a brevet of colonel. In 1864 he became assistant editor of the *Northwestern Christian Advocate* of Chicago and from 1872 until his death he was editor. He was honored by his denomination in many ways—in 1876 he was a member of the committee which revised the Church Hymnal, and he was a member of seven general conferences and of the ecumenical Methodist conference (London, 1881), before which body he read a noteworthy paper on "The Status of Methodism in the Western Hemisphere." For 12 years he was secretary of the Detroit conference. He was editor of the *Daily Christian Advocate* at the general conference of 1868.

EDWARDS, BELA BATES (1802-52). An American clergyman and author, born at Southampton (Hampshire Co.), Mass. He graduated at Amherst College in 1824 and at Andover Theological Seminary in 1830. In 1837 he was elected professor of Hebrew, and in 1848 associate professor of sacred literature, at Andover. At various times he was the editor of periodicals, including the *American Quarterly Register* from 1828 to 1842, the *American Quarterly Observer*, which he founded, from 1833 to 1835, and the *Bibliotheca Sacra* from 1844 until his death. He was also a founder of the Society for Ameliorating the Condition of the Slave and of the American Missionary Association. As a scholar and educator, he was very highly ranked. His published works include: *The Gazetteer* (1832); *The Biography of . . . Men, with an Introductory Essay* (1832); a *Memoir of Reverend Elias Cornelius* (1833); *Classical Studies: Essays on Ancient Literature and Art, with the Biography and . . . of Eminent Philologists*, with B. . . . C. Felton (1843); and a translation with S. H. Taylor (7th ed., 1860) of Raphael Kühner's *Schulgrammatik der griechischen Sprache* (Hanover, 1836). Two volumes of his addresses and sermons were published, with a memoir by Park (Boston, 1853).

EDWARDS, BRYAN (1743-1800). A West Indian merchant and author. He was born at Westbury, Wiltshire, and went to Jamaica in 1759, where he soon became a prosperous merchant. As a member of the Colonial Assembly, he advocated closer commercial relations with the United States. In 1792 he returned to England, established a bank at Southampton, and was elected in 1796 to the House of Commons. His principal literary production is the *History of the British Colonies in the West Indies* (5th ed., 1819; translated into German and partly also into Spanish). He also wrote a *History of St. Domingo* (1807; translated into French) and *Proceedings of the Governor and Assembly of Jamaica in regard to the Maroon Negroes* (1796).

EDWARDS, GEORGE WHARTON (1859- . . .). An American painter and illustrator, born at Fairhaven, Conn. He studied in Antwerp and

Paris and after his return to America exhibited frequently, and received a number of medals. From 1898 to 1903 he was director of the art department of *Collier's*, and thereafter he was with the American Banknote Company. He wrote and illustrated many stories of experience and travels, including *Thumbnail Sketches* (1886); *P'tit Matinee Monotones* (1887); *The Rivalries of Long and Short Codiac* (1888); *Break o' Day* (1889); *A Reading Journey in the Hollowland* (1908); *Brittany and the Bretons* (1910); *Old Flemish Towns* (1911); and also illustrated *The Last Leaf* of Holmes, the *Epithalamion* of Spenser, *Old English Love Songs and Ballads*, etc. His work as an illustrator for the best magazines in America is well known. His plates are well drawn, simple and direct in execution, and his water colors show daintiness and delicacy of finish. He also designed a number of effective posters and magazine covers and painted the mural decoration "Hendrik Hudson" in the United States Military Academy.

EDWARDS, HARRY STILLWELL (1855- . . .). An American journalist, novelist, and poet, born at Macon, Ga. He was a graduate in law of Mercer University, Macon (1877); served as assistant editor and editor of Macon journals (1881-88), gaining distinction as a writer of dialect stories. Noteworthy among his volumes are: *Two Runaways and Other Stories* (1889); *The Marbeau Cousins* (1898); *Sons and Fathers* (1896), a story that won a prize of \$10,000 in the Chicago Record; *His Defense and Other Stories* (1899). Mr. Edwards is strongest in studies of plantation life, as well among the Georgian aristocracy as among the negro laborers.

EDWARDS, HENRY SUTHERLAND (1828-1906). An English journalist and author, born in London and educated in that city and in France. He was correspondent of the London *Times* at the coronation of Alexander II of Russia (1856), in the camp of the insurgents at Warsaw (1862-63), at Luxembourg (1867), and at German army headquarters during the Franco-Prussian War. His publications include: *The Russians at Home and the Russians Abroad* (1861); *The Germans in France* (1874); *The Case of Reuben Malachi* (1886); *The Prima Donna: Her History and Surroundings from the Seventeenth to the Nineteenth Century* (2 vols., 1888); *Rossini and His School* (1895); *Personal Recollections* (1900); *Sir William White: His Life and Correspondence* (1902).

EDWARDS, JOHN PASSMORE (1823-1911). An English newspaper proprietor and philanthropist, son of a Cornish carpenter. About 1844 he became a representative of the *Sentinel*, a journal opposed to the Corn Laws. He was a delegate to peace congresses in Brussels, Paris, and Frankfurt (1848-50). His publishing ventures were failures for a time, but in 1862 he bought the *Building News*, with which he made money, and in 1876 he bought the pioneer half-penny evening paper, the London *Echo*, of which he was editor for 20 years. He was a member of Parliament in 1880-85 and in politics was a follower of Gladstone until the Home Rule Bill. He founded several "Passmore Edwards Institutions," public libraries and settlements—especially in London and Cornwall—and a scholarship at Oxford for the study of English and classical literatures together. He twice refused knighthood. His opposition to

the Boer War made him somewhat unpopular. Consult his privately printed autobiography. *A Few Footprints* (London, 2d ed., 1906).

EDWARDS, JONATHAN (the elder) (1703-58). The most celebrated early American divine and metaphysician. He was born at East Windsor, Conn., Oct. 5, 1703, the only son in a family of 11 children of the Rev. Timothy Edwards, the parish minister. He was a precocious child and at 13 entered the Collegiate School at Saybrook, afterward Yale College. Here his mind turned most readily to the profounder studies, and when he graduated with the valedictory at New Haven in 1720, he had already arrived at those great leading principles which formed the staple of his later thinking and constitute his chief contribution to the thought of his age. He was deeply influenced by Locke, whose *Essay* he read with eager interest in his sophomore year. This influence, combined with others more or less obscure, led to the construction of an outline of idealistic philosophy closely akin to Berkeley's. After graduation he was for a time tutor in his college. In 1727 he was ordained and installed colleague with his grandfather, the Rev. Solomon Stoddard, in Northampton, Mass., where he continued till dismissed in 1750. In 1731 he preached in Boston as the "public lecture" a sermon, *God Glorified in Man's Dependence*, which won him immediate recognition as a leader in the defense of Calvinism in a community largely affected by tendencies popularly designated as Arminian. In 1734 he delivered in Northampton a series of discourses, including a remarkable sermon on the *Reality of Spiritual Light*, combining the theology of Calvinism with a deep spirit of mysticism. The result was a revival in his parish, the prelude to the "Great Awakening" of 1740 and the following years, in which Edwards was a leader. The town of Northampton was transformed, but in the country at large the value and genuineness of the revival was much questioned. Edwards was therefore led into an elaborate defense of it in his treatise *Faithful Narrative, etc.* (1736). Other works of this period are directly or indirectly connected with the revival: *Distinguishing Marks of a Work of the Spirit of God* (1741); *Thoughts on the Revival of Religion* (1742); and *The Religious Affections* (1746), his chief work in experimental religion. He had now become a power throughout New England and had acquired a well-founded fame even across the seas.

But the regular progress of his life was to be rudely interrupted. It had been the custom under his predecessor to admit persons not of scandalous life, but not professing conversion, to the Lord's Table as a means of grace. Edwards became convinced by the experiences of the revival that this practice, so contrary to the original theory and practice of New England, was mischievous, and that no one ought to be admitted to membership in the church or to the communion who was not by personal profession and in "the judgment of a rational charity" a true believer in Jesus Christ. As this position involved an application of an ecclesiastical discipline to which the parish had long been unaccustomed, and as the question was complicated by a case of discipline that had affected personally individuals of great prominence and influence in the town, the position which Edwards took aroused the most violent opposition.

He was not even allowed to explain his position in the pulpit and was obliged to print his defense (*Qualifications for Full Communion*), and that few of his parishioners read. In 1750 he was dismissed by council. His prospects were thus apparently ruined; but in fact he now entered into the period of his greatest literary activity, in which he laid the foundation of his enduring fame. He obtained an appointment as missionary to the Indians at Stockbridge, which he held for the following eight years. In the quiet of this secluded spot he wrote his *Freedom of the Will*, his *Nature of Virtue*, his *Original Sin*, and his *Dissertation Concerning the End for which God Created the World*, possibly the most profoundly speculative philosophical work of the century. Here, too, he continued his acquaintance with the first and principal in the line of his successors and members of his "school," Samuel Hopkins. In 1758 he reluctantly accepted the presidency of the college in Princeton, N. J., but after a few weeks of service was removed by death, March 22, 1758.

Edwards's great fame rests upon his work as a theologian in the defense and development of the evangelical system. He was originally, and remained, a strong Calvinist. His first published discussion, that on God's sovereignty and man's dependence, shows him to be a thinker of exceptional power, and although his sermons on justification were marked by a certain conventionality of treatment, indicating the controlling influence of the Calvinistic tradition, there is even here the suggestion of a new spirit, as when faith is defined in a way unknown in the previous century, and identified with repentance as constituting with that the indivisible act of conversion. The treatise on the *Freedom of the Will* is an unwavering defense of determinism and contends not only that this is the teaching of Scripture and reason, but that any other view is false, absurd, and inconceivable. At the same time he earnestly repudiates the identification of this teaching with fatalism or any doctrine of necessity which denies to man the liberty essential to responsibility. The doctrine which he maintains is in fact only the position of Locke, and other writers who contend that the will is always determined in its preferences by the strongest motive, and his philosophical arguments are all drawn from their armory. But the fineness, the dialectical skill, the detail with which every conceivable objection is brought forward and demolished, and the tremendousness of the general effect, are all Edwards's own. While too much praise has often been lavished upon the book as a contribution to the permanent advancement of the theme, too much cannot well be said of its perfection of form, or of the influence which it immediately obtained and has continued to hold. It is probably the most famous book in theology that America has produced and one of the most famous philosophical works of the world. But there was much that was new in Edwards and which was destined to begin a distinct theological movement in America. In the treatise on *Original Sin* suggestions looking to a new emphasis on the voluntary character and personal nature of sin were made, which, in combination with suggestions in the *Freedom of the Will* concerning the natural power of man, led ultimately to a new anthropology, in which the doctrines of original sin, imputation, ability,

and regeneration were to undergo much modification. (See NEW ENGLAND THEOLOGY.) More directly influential was the treatise on the *Nature of Virtue*. The doctrine set forth in this work rests on the identification of being and value: the more truly real an object is, the greater is its intrinsic worth. The essence of virtue, accordingly, is love of an Infinite Being, or God, and the moral attributes of God are included in a love whose object is ultimately Himself. The virtuous love of particular being is regulated by this principle. The treatise was a posthumous one, its leading ideas were at once adopted by Hopkins and became the underlying motive of the theory of the atonement propounded by Edwards's son. They also became the characteristic principles of the school of thought called "New England," or often "Edwardean," from Edwards himself. Other suggestions are to be found scattered up and down the pages of Edwards, many of which have greatly influenced his followers. But most of all, perhaps, should be noted his utter loyalty to truth and his fearlessness in accepting all the consequences which logically implied in his premises.

Edwards was preëminently a religious man. As a child, he was profoundly influenced by the thought of God. He displayed modesty, humility, and serenity of spirit. His engaging personality was constantly in theological discussion; he is impersonal, calm, just, fair, and candid in his method of conducting the discussion. He was a student from his childhood, and extended his studies over pretty much the entire range of knowledge of his day. As a preacher, he was one of the best of his age. His ability to hold the attention of his audiences to long and careful trains of thought till he had convinced and won them would of itself illustrate this statement. But the well-known instances of his great power over congregations, as in the sermon at Enfield, where the people rose in their seats and wept and sobbed as he described the state of the lost, till he was obliged himself to ask them to be still, prove his ability to stir the feelings profoundly and that he felt profoundly himself.

Editions of his works are the Worcester (1808), originally in 8 vols., reprinted with additions, in 4 vols. (New York, 1858); and (the best) the Dwight edition in 10 vols. (ib., 1829-30), with memoir. Supplementary material may be found in the following: *Selections from the Unpublished Writings of Jonathan Edwards*, ed. by A. B. Grosart (Edinburgh, 1865); *Observations Concerning the Scripture Economy of the Trinity*, ed. by E. C. Smyth (New York, 1880); *An Unpublished Essay of Edwards on the Trinity*, ed. by G. P. Fisher (ib., 1903); *Selected Sermons of Jonathan Edwards*, ed. by H. N. Gardiner (ib., 1904). Some of the early writings, including the essay on the Flying Spider and fragments of a philosophical character, were carefully edited from the manuscripts by E. C. Smyth and published in the *Andover Review* (1890) and the *Proceedings of the American Antiquarian Society* (1895). Allen's *Jonathan Edwards* (Boston, 1889) is a noteworthy biography and appreciation.

EDWARDS, JONATHAN (the younger) (1745-1801). An American theologian, born at Northampton, Mass., the second son of Jonathan Edwards the elder. Early left an orphan, his education was provided for by friends, and he was graduated at Princeton in 1765. While in

college he was converted and after graduation studied theology with the friend of his father, Joseph Bellamy, of Bethlehem, Conn. He was tutor in Princeton (1767-69), pastor in White Haven, Conn. (1769-95), in Colebrook, Conn. (1795-99), whence he went to the presidency of Union College, Schenectady. As a theologian, his fame rests upon his reply to Chauncy upon the salvation of all men, in which he defended the usual evangelical doctrine; his reply to Samuel West's *Essays on Liberty and Necessity*, in which he largely modified his father's theory of the will by giving it a liberal interpretation scarcely reconcilable with its plain meaning; and upon his sermons on the atonement. He took part, in the last work, in the Universalist controversy then raging in New England. The Universalists of the Murray school had argued upon the basis of the standard Calvinistic theory of the atonement, that Christ had satisfied justice in behalf of all those for whom He died and paid their debt before God. But He had died for all men; therefore all men are saved. Edwards rejected the conclusion as against the Bible. But he could not deny that Christ died for all; and he therefore was led to teach that Christ did not satisfy justice in the sense of the full payment of a debt, but that the suffering of Christ was the exhibition of God's hatred of sin and love of man and so tends to draw men to God. The main idea was borrowed from Grotius, but the ideal basis of the atonement in the love of God was a new feature. Edwards thus founded the "New England" or "governmental" theory of the atonement, which maintained its place as the generally accepted theory among Congregationalists and "New School" Presbyterians for well-nigh a century. His works were published at Andover (1842), in 2 vols., with a memoir by Tryon Edwards.

EDWARDS, MATILDA BETHAM. See BETHAM-EDWARDS, MATILDA.

EDWARDS, PIERREPONT (1750-1826). An American lawyer, son of Jonathan Edwards the elder, born at Northampton, Mass. He graduated at Princeton in 1768, was admitted to the bar, began practice at New Haven, Conn., in 1771, and served in the Revolutionary army. In 1787-88 he was a member of the Continental Congress and later became United States district judge for Connecticut. He founded the Toleration party in Connecticut, and his energy in this cause made him hated by the Colonists. After the treason of Benedict Arnold he became administrator of that officer's estate.

EDWARDS, WILLIAM (1770-1851). An American inventor, the grandson of Jonathan Edwards the elder. He was born in Elizabethtown, N. J. He introduced a valuable improvement in the manufacture of leather, whereby tanning was accomplished in a quarter of the usual time. This and other improvements and machines introduced by him, including a rolling machine, greatly advanced the production of leather in America. Consult his memoirs (Washington, 1897).

EDWARDSVILLE. A city and the county seat of Madison Co., Ill., 23 miles northeast of St. Louis, Mo., on the Wabash, the Illinois Traction, the Toledo, St. Louis, and Western, the Litchfield and Madison, and the St. Louis, Troy, and Eastern railroads (Map: Illinois, D 8). It is in an agricultural and coal-mining district and has extensive manufactures of tools, plumbing supplies, brass finishings, radiators, single-

trees, buggies, etc. The city has a Carnegie library. Settled in 1812, Edwardsville was incorporated in 1819 and at present is governed under a charter of 1872, which provides for a mayor, elected every two years, and a city council. Pop., 1900, 4157; 1910, 5014. The Kickapoo Indian Agency was situated in Edwardsville, and it was here that the United States negotiated with the Indians for a tract of land comprising more than 10,000,000 acres, now a part of the great Illinois corn belt.

EDWARDSVILLE. A borough in Luzerne Co., Pa., 2 miles west of Wilkes-Barre, on the Delaware, Lackawanna, and Western Railroad (Map: Pennsylvania, K 4). It is purely a residential place. Pop., 1900, 5165; 1910, 8407; 1914 (U. S. est.), 9787.

EDWIN, or EADWINE (c.585-633). A king of Northumbria. He was the son of Ella, King of Deira, and was only three years old on the death of his father, in 588. Deira was invaded by Ethelric, the King of Bernicia, and the infant Edwin was carried by his guardians into North Wales, where he was brought up. Later he lived as an exile under the protection of Cearl, King of Mercia, and Raedwald, the ruler of East Anglia. The latter in 617 raised an army, defeated and slew Ethelfrith, who had succeeded his father Ethelric, and restored Edwin to his father's throne. Soon after his return to Deira Edwin succeeded in reducing Bernicia and established the Kingdom of Northumbria. He speedily extended his power over a large part of England, his authority stretching as far west as the islands of Anglesea and Man and as far north as the town of Edinburgh, which he is believed to have fortified, and which still bears his name. Especially after 626, when he defeated the West Saxon King, Edwin was suzerain practically of all England save the Kingdom of Kent, with whose ruler he was in alliance, having married the King's sister, Ethelburh, in 625. Ethelburh was a Christian, and owing to her influence and the exhortations of the missionary priest Paulinus, Edwin with his entire witan was brought over to Christianity in 627. He had previously been acknowledged as Bretwalda, or leader of the English, and his power increased greatly after his conversion. In 633 Penda, of Mercia, the most powerful prince in England after Edwin, and a follower of the old heathen religion, united with the Welsh against the Northumbrian King, and on Oct. 12, 633, inflicted an overwhelming defeat upon him at Heathfield. Edwin himself was killed, the Kingdom of Northumbria fell apart, and Christianity for a time was extinguished in northern England. Consult: Green, *The Making of England* (London and New York, 1881); Hodgkin, *History of England to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EDWIN AND AN'GELINA. A poem by Oliver Goldsmith, printed privately for the amusement of the Countess of Northumberland late in 1765 and afterward published in the *Vicar of Wakefield*.

EDWIN DROOD. See MYSTERY OF EDWIN DROOD.

EDWY, or EADWIG (c.939-959). A king of the English. He was the eldest son of Eadmund I and succeeded his uncle Eadred in 955. Dunstan (q.v.) bitterly opposed his marrying Ælfgifu, "because they were too near akin," and was banished from the kingdom for his pains;

but not long afterward he was recalled by the Mercians, who had revolted from Edwy and proclaimed his brother Eadgar King. Edwy was forced to share the kingdom with his brother. He died Oct. 1, 959. Consult Hodgkin, *History of England to the Norman Conquest* (London, 1906), and Oman, *England before the Norman Conquest* (ib., 1910).

EECKHOUT, ak'hout, GERBRAND VAN DEN (1621-74). A Dutch portrait and historical painter and etcher. He was born in Amsterdam and studied with Rembrandt, whose composition, color, and treatment of light he imitated so well that his early pictures are sometimes confounded with those of the great master. In portrait painting Eeckhout had a superior talent for expressing character. Among his best portraits are: "The Four Superintendents of the Wine Merchants Guild" (National Gallery, London); the historian Dapper (Städel Museum, Frankfurt); "A Man and a Woman in Black" (Darmstadt Gallery); Jan de Witt (Grenoble Museum). His most important paintings include: "The Raising of Jesus' Daughter" (Berlin Museum); "The Woman Taken in Adultery" (Amsterdam Gallery); "Jacob's Dream" and the "Presentation in the Temple" (Dresden Gallery). His etchings closely resemble those of Rembrandt, whom he often assisted.

EECLOO, ā-kloo'. A town of Belgium, in the Province of East Flanders, 11 miles northwest of Ghent (Map: Belgium, B 3). It has manufactures of lace, cotton, and woolen fabrics. It also has a considerable trade in grain. Pop., 1900, 12,897; 1910, 13,536.

EEDEN, ā'den, FREDERIK VAN (1860-). A Dutch author. He was born in Haarlem, studied at the University of Amsterdam, and became a practicing physician at Büssum. His *De kleine Johannes* (1887; 6th ed., 1900), a story of animal life, attracted great attention. Others of his works are the important poems, *Johannes Viator* (a sequel to *De kleine Johannes*, 1892), *Ellen* (1891), *De passieloos Lelie* (1901), *Enkele Verzen* (1898), and the novel *Van de Koele meren des doods* (1900). Among his dramatic works are *Ysbrand* (1910) and *Lioba* (1912).

EECKHOUD, ak'hout, GEORGES (1854-). A Belgian novelist and poet, born in Antwerp. His early poems, *Myrtes et cyprès* (1876), *Zigzags poétiques* (1877), and *Les pittoresques* (1879), were romantic. His short stories (*Kermesses*, 1884) showed a trend to realism, accentuated in his first novel, *Les milices de Saint-François* (1886), where the naive mysticism of Flemish peasant life is finely suggested. *La nouvelle Carthage* (1888), his masterpiece, is a realistic picture of life in Antwerp. Noteworthy also are: *Les fusillés de Malines* (1890), a story of the peasant revolt against the French in 1798; *La faneuse d'amour* (1900); *L'autre vue* (1905). Consult V. Thompson, *French Portraits* (Boston, 1900).

EEL (AS. *æl*, Ger. *Aal*). An elongated, serpent-shaped fish of the order Apodes (q.v.), soft-rayed, without ventral fins, and having the long dorsal fin confluent with the anal around the tip of the tail. The skin is smooth and exceedingly slimy and slippery. It may contain small scales, or scales may be entirely wanting. The vertebrae, because of the elongated form of the body, are very numerous. The best-known eels are the fresh-water eel (*Anguilla anguilla*, or *chrysypa*), belonging to the family

Anguillidæ, and the scaleless conger eel (*Leptocephalus conger*), of the family Leptocephalidæ. The common fresh-water eels, which have minute scales imbedded in the skin, occur on both sides of the Atlantic and ascend rivers and live there for the most part, returning to the sea in the autumn, or they may bury themselves in the mud during the winter. Sometimes they are dug out of the mud of river banks where large numbers of them may be found congregated together. Their activities and migrations seem to take place mostly during the night. They frequently make excursions on land in the moist grass for considerable distances, the purpose of which is not well understood.

The reproduction of the eel has excited the attention of naturalists since the days of Aristotle. In 1763 an eel-like fish, taken off the English coast by William Morris, was named *Leptocephalus*. Numerous specimens have since been obtained all over the world, and the family Leptocephalidæ has been erected to contain the various species which have been described. These creatures are thin as paper, transparent, and about 3 inches in length. It was suggested that the Leptocephalidæ are larvæ of eels, and this has been shown by Delage and by Grassi and Calandruccio, as a result of breeding experiments, to be the case, for as they developed they revealed all the characters of conger eels. Eventually Grassi showed that one of these *Leptocephali* (*Leptocephalus brevirostris*), characterized by its small size, short body, and absence of pigment, is the young or larval stage of the common eel. The discovery of Grassi (1893) was facilitated by the peculiar whirlpool currents in the Strait of Messina which occasionally bring bottom organisms to the surface, and since the young eels are found at the surface with well-known denizens of the deep sea, it is concluded that the young develop at great depths (1500 feet). The entire reproductive history of the eel may now be given as follows: Eels that descend from the fresh water to the sea do so during the months October to January, and in a sexually immature condition, as has long been known. They go to the depths and live there for eight months or more, during which time they must become sexually mature. Where the eggs are laid is not known, whether at the bottom or near the surface. From 5,000,000 to 20,000,000 eggs are laid by each female, and the eels die after once spawning, none ever returning to the coast or rivers. Larvæ are found in spring and summer. In the autumn and winter, October to February, these young eels pass from the sea into fresh water in great numbers—immigrations which have long been known as eelfares; the fish themselves, now over a year old, are called elvers. About two years then intervene between the descent of the parent eels and the ascent of their progeny.

Eels are very voracious and will eat the most varied sort of food. They grow to a length of 4 to 5 feet. Although much prejudice against them exists in certain regions, they are important food fishes and are much eaten both in Europe and America. By many they are thought to be poisonous—a notion which may have its origin in the well-known fact that eel's blood transfused into the system of higher vertebrates is very poisonous; but the same is true of the blood of other animals, though perhaps to a smaller degree. *Anguilla*, of which there are

several species, is found in all warm seas except the east Pacific. Eels are trapped by eelpots and baskets and are extensively speared. The United States census of fisheries reported the number of pounds of eels taken in 1908 as 3,358,000 valued at \$203,000, nearly all being accredited to the Atlantic coast district. Consult: Schmidt, "Contributions to the Life-History of the Eel," in *Rapports et Procès-verbaux du Conseil international*, vol. v (1906); Murray, *Depths of the Ocean* (London, 1912); Lydekker, Cunningham, and Thomson, *Reptiles, Amphibia, and Fishes*, 1912; Smith, "Mysterious Life of the Common Eel," in *National Geographic Magazine*, vol. xxiv (Washington, 1913). See CONGER; ELECTRIC FISH; and PLATE OF EELS, CONGERS, AND MORAYS.

EEL/LEE. See ILI.

EELGRASS. See TAPE GRASS; VALLISNERIA.

EELLS, MYRON (1843-1907). An American Congregational clergyman, born at Walker's Prairie, Wash. He graduated at Pacific University, Oreg., in 1866, and at Hartford Theological Seminary in 1871. After holding a pastorate at Boise City, Idaho (1871-74), he became a missionary among the Indians at Skokomish, Wash., and later pastor of the Congregational church (1876). In 1893 he was appointed superintendent of the exhibit of Washington at the World's Columbian Exposition. His publications include: *History of Congregational Association of Washington and Oregon* (1881); *History of Indian Missions on the Pacific Coast* (1882); *Ten Years at Skokomish* (1886); *Father Eells* (1894); *Reply to Professor Bourne's "The Whitman Legend"* (1902); and monographs on the Twana, Chemakum, and Clallum Indians of Washington, on the Indians of Puget Sound, and on hymns in the Chinook language. He prepared for the Smithsonian Institution many Indian vocabularies.

EELPOUT (AS. *alepûte*, from *al*, eel + *pûte*, pout). 1. In England, and locally in the northern United States, the burbot (q.v.). 2. The mutton fish (q.v.). 3. A catfish (*Malapterurus*). See CATFISH.

EELWORM. Any of the threadlike nematode worms of the family Anguillulidæ, as the vinegar eel. Certain species in the East Indies cause a serious disease of sugar cane called sereh, and American species are injurious to cotton, the orange, peach, and other plants, by boring into the roots and root knot. Consult Neal, *United States Department of Agriculture, Bulletin 20* (Washington, 1889).

EËTION. See AËTION.

EFFECT (OF. *effect*, Lat. *effectus*, from *ef-ficere*, to accomplish, from *ex*, out + *facere*, to do). The impression which the mind receives at the sight of a work of art without taking cognizance of the details that contribute to it. In sculpture it is the movement and general shape of the mass, which first impresses and produces the effect. In painting, effect is produced by the force of color, the balance of light and shade, and by composition. Bold sketches of their works are sometimes made by artists beforehand, for the purpose of adjusting the composition and coloring so as to produce the desired effect.

EFFENDI (Turk. *efendi*, gentleman). A term of respect among the Turks, corresponding to our Mr. or Sir, or the French *monsieur*. The title is frequently added to the name of an office

EELS, CONGERS, AND MORAYS

1. A PELAGIC EEL (*Derichthys serpentinus*).

2. A PELAGIC EEL (*Quassiremus evionthas*).

3. DEEP-SEA PARASITIC EEL (*Simenchelys parasiticus*).

4. COMMON EEL (*Anguilla chrysypa*).

5. SPOTTED MORAY (*Lycodontis moringa*).

6. CONGER EEL (*Leptocephalus conger*).

7. SNIPE EEL (*Labichthys carinatus*).

and always follows the name with which it is used. See BASHI; REIS EFFENDI.

EFFIAT, HENRI COFFIER RUZÉ D'. See CINQMARS.

EFFICIENCY. A term taken into specialized use about 1908 and since then increasingly employed to designate the aim or character of a widespread movement towards betterment in both profit-making and nonprofit-making activities. This movement has found expression in two national efficiency societies, in a very large volume of literature devoted to the principles and practice of efficiency, and in a general tendency so to modify industrial and operating organizations or administrative bodies as to provide systematically for the conduct of the work in hand according to these principles and practice.

As thus adopted into modern industrial, economic, and sociological parlance, efficiency expresses a concept different from, though intermediate between, its older general sense of the quality of producing desired effects, or effectiveness, and its later mechanical sense which is the ratio of useful work performed to energy expended, or, as it is more briefly expressed, ratio of output to input.

In its newer usage efficiency is both titular and descriptive, and the meaning conveyed in its descriptive use is closer to the mechanical than to the general definition above quoted. That is, it recognizes the mechanical idea of balance between energy furnished and work returned, but it recognizes also that unpreventable losses occur in every cycle of operation or transformation, and it does not charge these against the efficiency of the process or the agent which must work in that cycle.

The pursuit of efficiency thus becomes a diligent effort to discover and remove preventable losses and wastes so that the largest returns may be secured for the least expenditure. Its minor function may be that of increasing energy applied, or, in other words, adding to input. Its major function must be cutting off unfruitful expenditures of energy, and saving output which has been wasted on something different from the purpose desired. This distinguishes it sharply from effectiveness, which, per se, is only the achievement of result by increase of input, without any necessary consideration of the actual expenditure incurred. An effective performance may also be an efficient performance. On the other hand, an effective performance may be inefficient because it wastes resources in reaching its achievement; and an efficient performance may be ineffective because, though it conserves and applies its resources with the utmost skill, the resources available are insufficient for the work in hand.

A dynamite cartridge would be very effective in removing a gem from its matrix, but it would not be an efficient agent in the hands of the miner if it blew the stone to atoms in the process. Vice versa, a skilled man might work most efficiently to detach the stone (i.e., might accomplish all that human skill and toil are capable of) and still might be ineffective because the task exceeded his means of attack.

Efficiency is thus determined by measuring results or conduct against standards, and these standards must be fixed with full consideration of the ideals or purpose in view. For example, in taking down a historic building to be reerected elsewhere, circumspection, deliberation, careful

handling, and systematic preservation are qualities of efficiency. In removing the same building to stop an advancing conflagration, swift and utter demolition becomes in turn an efficient characteristic. In the former case the preventable losses are losses of material and of records of its position. In the latter case the preventable losses are loss of time and loss of opportunity. Efficiency therefore depends on adopting the best available methods to realize the highest attainable standards in the achievement of ideals. The first principle of efficiency is ideals, but the second is common sense, and stress is therefore laid on the qualifications available and attainable in the proposition just stated.

The concept is universally applicable, and the efficiency movement therefore appears in many fields—political, social, educational, etc.—the first of the new societies above mentioned all these fields are represented. The second, called the Western Efficiency Society, represents especially profit-making activities. For efficiency principles applied to nonprofit organizations, the reader is referred to: *Principles of the Efficiency Society*, vol. i, published by the society (New York, 1912).

Promotion of industrial efficiency has been sought by various workers advocating methods of many kinds, addressed sometimes to bodily, sometimes to mental, and sometimes to technical, conditions. Under the first heading fall generally the varying forms of welfare work (q.v.); under the last should be classed most of the formalized wage systems and the main portion of the scheme of scientific management (q.v.); under the second, or psychological, are grouped philosophies like the unit system (q.v.) or the committee system, which operate largely by suggestion. Also, by overlapping, we should place here some features of the wage systems which, while superficially wholly material, are found on deeper examination to derive part of their motor impulse from psychological suggestion.

In every doctrine or suggested form of practice belonging in these organized efficiency efforts, some or all of three elementary factors will be found operative. These are:

First, standardization, which means broadly determining the best way of doing the work in hand under the best conditions that can be established in the circumstances, and providing the means for thus doing it with the least loss or waste. This is like clearing the course and preparing the track for the runner so that all his expended energy may carry him towards the goal and none be wasted in overcoming obstacles.

Second, instruction to the worker in performing the task by this best attainable (i.e., standardized) way. This is like training the runner.

Third, incentive—a reward proportioned to individual efficiency to persuade the worker to accept the prepared conditions and the expert guidance and thus to make the most of himself and of the opportunity. This is like the prize or record won by the runner of the race.

The principal modern systematized attempts to increase industrial efficiency are treated at greater length under separate headings, to which references are given in the short comparative statement below. They codify practice which in many cases is much older, but which had not formerly been identified and reduced to expression. The first to attract wide attention in America was the premium plan (q.v.), described by F. A. Halsey in 1891. In this the standard is merely

past performance, and the incentive is half the wage value of any time saved by the worker. The factor of instruction does not appear, the assumption being that the worker already has more knowledge than he is using and will release this reserve store of information and skill under the incentive of the added wage premium.

Next (1896) came the F. W. Taylor differential piece rate. (See SCIENTIFIC MANAGEMENT; WAGES.) In this standardization was still further emphasized. Fixation by careful study of the best time in which the work could reasonably be done replaced mere record of the time in which it formerly had been done. Standardization of tools and fixtures as well as of time was suggested, though not emphasized. Instruction was not clearly provided for, but was implied to a greater extent than in the premium plan. Incentive took the form of higher pay per piece for work finished in the standard time than for work taking a longer time than standard.

Five years later (1901) followed H. L. Gantt's task work with bonus (q.v.). Accepting and building on all that had been done in standardization of task and time, this doctrine added largely to standardization of conditions and was foremost in emphasizing and providing for individual instruction to the worker in the performance of the standard task. Incentive was given the form of a large percentage increase to the day wages of the conforming and successful worker.

Shortly thereafter (1903) appeared Taylor's *Shop Management*, setting forth the system now titularly styled scientific management (q.v.). Here standardization is extended to the limit, governing not only task, time, and workers' movements, but organization, administration, and management.

A new form of organization and a new practice of administration, known as functional management, are devised for the purpose, first, of advance planning, and, second, of constant supervision of every job. Not only the task, but the method of assigning the task and of superintending the task, even of naming the task and the appliances, are thus standardized. The incentive may be either the differential piece rate or the bonus—in either case a substantial increase of pay to the man who cooperates with the management in reaching the standard. This system is sometimes styled by its disciples ultimate management. It is intensive in its treatment of the material factors of the production problem and in its specification of exact ritual for every detail.

In the philosophy formulated by Harrington Emerson in 1908 and first known as the efficiency system appears a similar concept of the necessity of standardizing the management as well as the men's work. The underlying idea, however, differs radically from Taylor's functional separation of the managing organization into two parts, each again subdivided into four functional activities. Emerson leaves the line organization intact, but brings in an expert staff to guide and counsel the line in all its more important duties and problems. His standardization of tasks is reached not so much by building up from analyzed elements as by correcting actual performance by eliminating preventable wastes. His incentive plan, instead of waiting until the man fully achieves a task, begins to encourage him by some small increment as he

he has advanced two-thirds of the way to standard achievement and increases the reward on a rising scale as perfection is more and more nearly approached. More significant, however, in this philosophy is the categorical recognition of psychical qualities as necessary to efficiency in practice. Twelve principles are acknowledged as necessary to efficient guidance and conduct of any enterprise. They are: ideals; common sense and judgment; competent counsel; discipline; the fair deal; reliable, immediate, and accurate records; planning and dispatching; standards and schedules; standardized conditions; standardized operations; written standard-practice instructions; efficiency reward.

Last, but by no means least interesting are the theories and practice dependent chiefly on psychological suggestion. Such are the committee system (see LEGISLATIVE MANAGEMENT) of Charles U. Carpenter and the unit organization (q.v.), of Major Charles De Lano Hine. In both of these, with almost nominal outward change in organization, with little or no change in equipment, and perhaps none whatever in wage matters, the men in whose power it lies to increase the efficiency of operation are given a new vision and a new interpretation of their responsibility and their relation to the undertaking as a whole. This may be done, as in the Carpenter system, by assignment to committees with stated conferences. It may be done, as in the Hine system, by a change of title and of nominal province without a change of specialized interest. In either case the same great factors of standards, incentive, and (to less degree) instruction can be discerned though under much subtler forms.

In general, the more specific and detailed and the more highly formalized any scheme for the promotion of efficiency is, the more limited the range of situations to which it is applicable, and the more it tends towards a selective sifting out of standard individuals for some special work and the elimination of the unfit. On the other hand, broad and elastic measures for the promotion of fundamental principles are adaptable to a wide range of cases and to shifting conditions and tend towards a general raising to some extent of the efficiency of all who come under their influence. Each of these effects is important. The specific measures to be adopted in any given case and the steps by which they should be applied are matters for determination by a specialist.

Goldmark, *Fatigue and Efficiency* (ib., 1912).

EFFINGHAM. A city and the county seat of Effingham Co., Ill., 101 miles east by north of St. Louis, Mo., on the Vandalia, the Wabash, and the Illinois Central railroads (Map: Illinois, G 7). There are situated here colleges of photography and of photo-engraving. The chief industrial establishments are a milk-condensing

plant and a canning factory. Settled about 1850, Effingham was incorporated as a city in 1869. Pop., 1900, 3774; 1910, 3898.

EFFLORESCENCE (from Lat. *efflorescere*, to blossom, from *ex*, out + *florescere*, inchoative of *florere*, to bloom, from *flos*, flower). A phenomenon exhibited by many crystalline compounds when exposed to the air; the compounds lose their water of crystallization and change into pulverulent masses. The white incrustation that frequently shows itself on the walls of buildings is an example of efflorescence.

EFFORT (OF. *effort*, *esfort*, Fr. *effort*, It. *sforzo*, from ML. *effortiare*, to strengthen, from Lat. *ex*, out + *f*...). Primarily effort, or strain, is a... which is derived from the tendons. When we are active, as in wrestling, pushing, pulling, lifting, we term it effort, or exertion; when we are passive, as in supporting a weight, or standing for a long time on one leg, we term it strain. The quality, however, is the same throughout.

The term "effort" is also used to express the conscious strain which is present in ratiocinative thinking, as in solving a problem. This kind of effort is sometimes called "mental effort" or "mental work"; although the tendinous sensations accompanying severe muscular exertion are no less mental and, as conscious experiences, are the same in kind as the effort realized in "hard thinking" or in an attempt to remember, or in the struggle to decide on a course of conduct. The existence of effort has been used as an argument in favor of a peculiar activity of consciousness, as indicating that "mental force" is expended in voluntary action; but it may also be looked upon as simply a complex of intensive organic sensations strongly toned with unpleasantness. In this case the "work" is performed by the physiological processes accompanying effort. The prominent affective side of the experience is indicated in the common phrase "feeling of effort." Effort was for a long time held to be an essential part of the innervation sensation (q.v.); i.e., the sensation which was said to accompany the outflow of energy from the brain to the motor nerves. But this position has now been abandoned by most psychologists. See **ATTENTION**; **COXATION**. Consult Külpe, *Outlines of Psychology* (London, 1909), and Titchener, *Text-Book of Psychology* (New York, 1910).

EFFUSION (Lat. *effusio*, from *effundere*, to pour out, from *ex*, out + *fundere*, to pour). A term applied to the free outflowing of a gas through a pinhole, the resistance to the outflow being very small. The velocity of effusion was found by Graham in the case of different gases to be *inversely proportional to square roots of their densities*. The principle was applied by Bunsen to the determination of the relative densities of gases and hence also of their molecular weights. A modification of Bunsen's apparatus is now widely used in gas factories for rapidly testing the quality of gas. The amount of gas required for an experiment being very small, Debiérne was able to employ the effusion method for determining the molecular weight of radium emanation.

Quite different from effusion is the phenomenon of *transpiration of gases*, i.e., the outflow of gases through long capillary tubes offering considerable resistance to their passage. The rate of transpiration of a gas depends on four factors: (1) the nature of the gas; (2) the density of the gas; (3) the pressure under which it is

being expelled; and (4) the length of the tube. The first of these factors of course remains the same if one and the same gas is experimented upon under different conditions. The rate of transpiration is then found to be *directly proportional to the density* as well as to the expelling pressure and to be *inversely proportional to the length of the tube*.

The phenomena of effusion and transpiration are essentially different from those of diffusion. In the former the gases move *in masses*; in diffusion they move *by molecules*. See **DIFFUSION**.

EFT, or **EVET** (AS. *efete*). A term formerly applied popularly and scientifically both to lizards and newts. It is now synonymous with newt, and in the United States red eft, or evet, is a local name of the spotted newt (*Diemyctylus miniatus*). See **NEWT**.

ÉGALITÉ, a'gà'lè'tá'. See **ORLÉANS**, **HOUSE OF**.

E'GAN, MAURICE FRANCIS (1852-). An American scholar, born in Philadelphia and educated at La Salle College. In 1878 he became professor of English literature at Georgetown College, but subsequently he was successively associated with *McGee's Illustrated Weekly*, the *Catholic Review*, and *Freeman's Journal*, of which he was chief editor from 1881 to 1888. He was professor of English literature at the Catholic University, Washington, D. C., from 1895 to 1907, when he resigned to accept the post of United States Minister to Denmark. In 1913 he declined the ambassadorship to Austria-Hungary, offered him by President Wilson. His publications include a translation of Coppée's *Pater; That Girl of Mine* (1879); *Preludes*, a collection of poems (1880); *Songs and Sonnets* (1886); *The Life around Us*, a collection of tales (1886); *Lectures in English Literature* (1889); *The Disappearance of John Longworth*; *St. Martin's Summer* (1905); *The Ghost in Hamlet, and other Essays* (1906); *Amélie in France* (1912); *Everybody's St. Francis* (1912); *Notes on Agricultural Conditions in Denmark* (1913).

EGAN, PATRICK (1841-). An Irish-American politician, born in County Longford, Ireland. He became the head of an extensive flour and grain business in Dublin. An ardent Nationalist, he took an active part in the Home Rule movement in 1871 and in the organization of the Irish Land League, of which, in 1879, with Justin McCarthy and Biggar, he was one of the first trustees and the treasurer. In 1880 he was tried in Dublin for conspiracy and sedition, and after his acquittal he removed to Paris and in 1883 to the United States, settling in Lincoln, Neb. From 1884 to 1886 he was president of the Irish National League of America. His testimony before the Parliamentary Commission in 1889 brought about the collapse of the London *Times's* case against Parnell. He took an active part in the Blaine campaign of 1884 and for his services in the campaign of 1888 was made Minister Plenipotentiary to Chile. There his active advocacy of the cause of Balmaceda (q.v.) brought upon him severe criticism. In the campaigns of 1896 and 1900 he left the Republican party on the free-silver issue and campaigned for Bryan.

EGAN, PIERCE (1772-1849). An English writer on sports. He was born in London and by 1812 had attracted considerable attention there by his articles in the newspapers on country sports. A series of articles describing the

amusements of sporting men in town which were published under the title *Life in London; or, the Day and Night Scenes of Jerry Hawthorne, Esq., and his elegant friend, Corinthian Tom, Accompanied by Bob Logic, the Oxonian, in their Rambles and Sprees through the Metropolis* (1821), also became very popular among Londoners. This book was illustrated by George and Isaac Cruikshank, was one of Thackeray's early favorites, and is believed to have furnished the material for Dickens's *Pickwick Papers*. Several imitations and pirated reproductions of this famous work appeared. In 1824 he began to edit *Pierce Egan's Life in London and Sporting Guide*, a weekly newspaper later combined with *Bell's Life in London*. His other published works include: *Boxiana* (in several volumes, 1818-24); *The Life of an Actor* (1824); *Pierce Egan's Book of Sports and Mirror of Life* (1832); *The Pilgrims of the Thames in Search of the National* (1838).

EGAN, PIERCE (the younger) (1814-80). An English novelist and artist. He was born in London and at an early age became successful as an illustrator. He is best known, however, as a novelist. His extravagant yarns were exceedingly popular for a time, as also were his numerous contributions to the "penny-dreadful" papers of the day. Among his stories are: *Wat Tyler* (1841); *Robin Hood* (1842); *Snake in the Grass* (1858); *Eve; or, the Angel of Innocence* (1867); *Love Me, Leave Me Not* (1860).

EGAÑA, ā-gā'nyā. **JUAN** (1769-1836). A Spanish-American juriconsult, statesman, and author. He was born in Lima, Peru, and was educated at the College of Santo Toribio, where he was made a professor of philosophy at the age of 16, and professor of theology and law at 21. He practiced law at Santiago, Chile, whence he petitioned the court of Spain for the establishment of a chair of eloquence at the University of San Felipe. The chair was established, and he won it in public contest. He became one of the leaders of the revolution of 1810 and was elected a member of the first Chilean Congress. After the defeat of the Chilean army at Rancagua, in 1814, he was imprisoned by the Spaniards on the island of Juan Fernández, but was liberated through the victory of San Martín at Chacabuco in 1817, when he became professor of belles-lettres at the National Institute and member of the Board of Education. Upon the fall of O'Higgins in 1823, Egaña became President of the Constituent Congress of Chile; and the plan of a constitution sanctioned by this congress was his work. He was considered one of the best writers of his day, and his literary works, published in 10 vols. include poems and educational textbooks, as well as numerous essays on legal, political, and various other subjects. His *Cartas Pehuénchas* were translated into English by their author, under the title of *Pehuénchan Letters* (1819).

EGBERT, or EGBERHT (?-839). A king of the English. He was the son of Eahlmund, a king of Kent, and was descended from the early kings of the West Saxons. In his youth he was compelled to flee from England to avoid the hostility of Beorhtric, King of Wessex, and took refuge at the court of Charles the Great. Here he remained probably for some 13 years, until, in 802, he became King of the West Saxons. For the first 13 years of his reign nothing is known of his acts. In 815 he conquered and laid waste Cornwall. Between 825 and 829 he

subdued all the other kings in England, beginning with the ruler of Mercia, the most powerful rival of Wessex, and was recognized as Bretwalda. Kent, Sussex, and Essex were added to his kingdom and were ruled by his sons or nobles as vassals. He was permitted to retain their lands, and was acknowledged the supreme ruler of the Kingdom. For the first time Egbert brought all of the English peoples under one overlord. In his last years he had to contend against the Danes, by whom he was defeated in 835, and over whom he was victorious in 837. Consult *Anglo-Saxon Chronicle* (where the dates, however, are given wrongly); Green, *The Making of England* (London and New York, 1881); id., *The Conquest of England* (ib., 1883); Hodgkin, *History of England to the Norman Conquest* (London, 1906); Oman, *England before the Norman Conquest* (ib., 1910).

EGBERT, JAMES CHIDESTER (1859-). An American classical scholar and educator, born in New York City. He graduated in 1881 at Columbia University, where he afterward held tutorships in Greek (1885-87) and Latin (1888-95), was adjunct professor of Latin from 1895 to 1900, then professor of Roman archaeology and epigraphy and after 1906 professor of Latin. In 1902 he became in addition director of the summer session of Columbia University and later director of its system of extension teaching. His works include an edition of *Macmillan's Shorter Latin Course* (1892); *Cicero de Senectute* (1895); *Introduction to the Study of Latin Inscriptions* (1895); *Livy xxi and Selections from xxi to xxx* (1913). He contributed to the NEW INTERNATIONAL ENCYCLOPEDIA.

EGEDE, ā'ge-de, HANS (1686-1758). The first missionary to Greenland. He was born in Senjen, Norway, was educated at the University of Copenhagen, and was settled as a Lutheran pastor in 1706 and from 1706 to 1717. A study of the chronicles awakened in him a desire to visit Greenland and convert to Christianity the descendants of the old Northmen, who he believed still lived there. In 1721, having obtained the support of the Danish government, he sailed for Greenland, but, on arriving, he found that the former Norse colonists had entirely disappeared. However, he resolutely turned his attention to converting and civilizing the Eskimos. Though compelled to endure great hardships and privations, he founded a colony of Godthaab, converted many of the natives to Christianity, and established commercial relations with Denmark. In 1734 he was forced by ill health to return to Copenhagen, where he was for 6 years principal of a seminary in which workers were trained for the Greenland mission. In 1740 he became superintendent or bishop of the mission. He described his work in Greenland in *Det gamle Grønlands nye Perlestrætion* (1741) and is the author of a work on the natural history of Greenland, which has been translated into four languages.—**PAUL EGEDE** (1708-89), his son, succeeded him in the Greenland mission and later in the bishopric, translated the Gospels into the Greenland language and compiled a grammar and dictionary for the use of the missionaries and colonists. Consult Hamilton, *History of the Missions of the Moravian Church* (Bethlehem, Pa., 1901).

EGELHAAF, ā'gel-hāf, GOTLOB (1848-). A German historian, born at Gerabronn

(Württemberg). He studied at Tübingen, in 1895 became head of the Karls gymnasium at Stuttgart, and in 1901 lecturer in the technical institute there. Important among his publications are: *Kaiser Wilhelm I* (3d ed., 1888); *Deutsche Geschichte im Zeitalter der Reformation* (3d ed., 1893); *Geschichte der neuesten Zeit* (4th ed., 1912). He also wrote a popular manual, *Grundzüge der deutschen Literaturgeschichte* (22d ed., 1913).

EGER, ä'gër (Bohemian *Cheb*). A town of Bohemia, situated on an eminence 1450 feet above sea level, at the foot of the Fichtelgebirge, on the Eger, 66 miles west-northwest of Prague (Map: Austria, C 1). The chief building of interest is the Stadthaus, or town hall, in which, on Feb. 25, 1634, Wallenstein was assassinated. The hall contains a museum of local antiquities, pictures, and relics of the famous general. In an angle of the old fortifications above the river stand the ruins of the Imperial castle built by Frederick Barbarossa. From their midst rises a square black tower, constructed of blocks of lava. The graceful double chapel is worthy of notice. The Schillerhaus, in which the German poet stayed while writing *Wallenstein*, still stands. The institutions of the town include a teachers' college, an agricultural school, and an almshouse. Its manufactures include woolen, cotton, and other textile fabrics, chemicals, carpets, machinery, and leather goods. About 4 miles to the north of Eger and reached by a broad avenue is the watering place of Franzensbad (q.v.). Pop., 1900, 23,665; 1910, 26,619, mostly Germans. Eger was probably founded at the beginning of the twelfth century and came into the possession of Bohemia about 1320. The city suffered greatly in the wars of the Hussites, the Thirty Years' War, and the War of the Austrian Succession. Consult Drivok, *Altère Geschichte der deutschen Reichstadt Eger* (Leipzig, 1874), and K. Siegl, *Die Kataloge des Egerer Stadtarchivs* (Eger, 1900).

EGER, äg'ër. See ERLAU.

EGERIA (Lat., from Gk. Ἑγερία). One of the Italian goddesses of streams or springs. She appears in Vergil, *Aeneid*, vii, 763 ff., as the nymph of the stream in the grove of Diana at Aricia. In Livy, i, 19, 21, and Juvenal, iii, 12, she is represented as dwelling near the Porta Capena, at Rome, near the spot where Numa (q.v.) consecrated a grove to the kindred goddesses called Camenæ. Egeria is best known as the divine mistress or wife of Numa, whose inspiration and advice guided him in his reorganization of the ritual of the Roman state. According to Ovid, *Met.*, xv, 479-551, Egeria, after the death of Numa, went to Aricia, and, there, by reason of her ceaseless lamentations, was changed by Diana into a spring.

EGERTON, ej'ër-ton. FRANCIS. See BRIDGE-WATER.

EGERTON, FRANCIS, EARL OF ELLESMERE. See ELLESMERE.

EGERTON, HUGH EDWARD (1855-). An English historian, educated at Rugby and at Corpus Christi, Oxford. In 1886-1906 he was a member of the managing committee of the Emigrants' Information Office, and in 1905 he was appointed at Oxford Beit professor of colonial history, his special field. He wrote: *A Short History of British Colonial Policy* (1897; 3d ed., 1910); *Sir Stamford Raffles* (1900); *Origin and Growth of the English Colonies* (1902); *Canadian Constitutional Development*,

with Grant (1907); *Canada under British Rule* (1908); *Federations and Unions within the British Empire* (1911).

EGG (AS. *æg*, Icel. *egg*, OHG. *ei*, Ger. *Ei*; connected with OChurch Slav. *aye*, *yaye*, Lat. *ovum*, Gk. *óov*, *óon*, egg). The present article proposes to consider the external characteristics, qualities, and utilities of the eggs of animals, and more especially of birds, leaving to the articles EMBRYOLOGY, REPRODUCTION, ETC., their biological relations and development. All animals except Protozoa produce eggs, which are essentially single cells of protoplasm, each with a nucleus in which rests the nucleolus, plus, in most cases, food material and an oil droplet. Eggs may be produced singly or in very small numbers at long intervals, or frequently and in great numbers; they may be so minute as to be invisible to the unaided human eye or may exceed a foot in diameter; and in relative size, as compared with the parent, they may be nearly a quarter as large or less than a millionth; they may never leave the parent except as waste matter, or may be extruded, either before or after fertilization. Finally, those which are "laid" may be cast out wholly naked to take an infinitesimal chance of survival, or may be more or less well secured against harm by protective coverings, or even become objects of care and protection on the part of the parents.

Eggs of Birds. The eggs of birds will be considered first, because they are typical, familiar, and of most interest to the general reader. They are the largest, relatively to the size of the parent, of any in the animal kingdom, owing to the fact that the embryos must reach a higher degree of maturity (and bulk) before hatching than among inferior classes of animals. The egg originates in the ovary, where, as the breeding season approaches, a number of them become greatly enlarged and one by one break loose from the ovarian membranes and begin to descend the oviduct. They are at this time simply spheres of yolk, each containing all quantity of germinal protoplasm, a small portion of the original cell), which appears on the surface of one side, as the "tread" of popular speech (see ALLANTOIS; EMBRYOLOGY), and covered with an almost imperceptible membrane, the vitelline membrane, formed from the protoplasm of the egg itself. Yolk, or deutoplasm, is a granular, fatty, nutritive material or highly compact food, stored in the egg for the nourishment of the young. It is of two kinds, white and yellow. The white yolk forms a thin film over the surface of the yellow yolk, and passes also under the germinative vesicle, where it forms a sort of bed, and from this point extends downward to the centre of the yellow yolk. The egg is passed into the sac-like mouth of the oviduct and then descends into the oviduct itself, where it is, or may be, fertilized, and along which it descends in a slow spiral course.

Here the yellow ball begins to receive its outer coverings, the first of which is the "white," or albumen, which is poured out from glands, and consists of about 86 per cent of water, 12 per cent of protein, 1.5 per cent of fat, and a little salt. The "white" of the egg is formed in concentric layers (as may be seen in a hard-boiled egg), the innermost of which is somewhat tenacious, and is drawn out by the spiral rotation of the egg in its progress into threads at the opposite poles. "These threads," writes Coues, "which become twisted in opposite directions,

... are called *chalazæ*; they are the 'strings' rather unpleasantly evident in a soft-boiled egg, but serve the important office of mooring and steadying the yolk in the sea of white by adhesions eventually contracted with the membrane which immediately lines the shell. They are also intrusted with the duty of ballasting, or keeping the yolk right side up. For there is a 'right' side to the yolk ball, being that on which floats the cicatrice, or 'tread.' This side is also the lightest, the white yolk being less dense than the yellow; and the *chalazæ* are attached a little below the central axis. The result is that, if a fresh egg be slowly rotated on its central axis, the tread will rise by turning of the yolk ball in the opposite direction, till, held by the twisting of the *chalazæ*, it can go no further: when, the rotation being continued, the tread is carried under and up again on the other side, resuming its position. The earliest embryologists (e.g., De Meijere, 1600) attached considerable importance to the *chalazæ* and to certain white particles, the granules, contained in them, because these structures were erroneously supposed to give rise to the embryo bird.

The Eggshell. The deposits of albumen are overlaid, when the egg arrives at the constricted neck of the uterus, by a membrane secreted by the lining of the oviduct and formed of albumen mixed with felted fibres. This is the egg pod lining the shell. It is double, and by the separation of its two layers at one end the air chamber is formed. The egg, now five or six hours old in the case of the common fowl, passes on into the uterine dilatation of the oviducts, where it rests for about 20 hours and receives from numerous villi in the lining of the walls an even coating of a viscid fluid thickly imbued with lime, which rapidly crystallizes and compacts into a calcareous, somewhat felted shell around the whole egg. This is attached at many separate points to the shell membrane, leaving numerous minute spaces between them filled with air through pipelike interstices in the shell. "Besides this mammillary and porous layer, the shell of most birds," according to Newton, "possesses a cuticular layer. This outermost layer is the most variable part of the shell; it is apparently structureless, either very poor in calcine salts and in this case smooth and shiny, or considerably infiltrated with calcareous matter and then exhibiting the well-known chalky and often rough appearance of the eggs of the ani, cormorants, grebes, and flamingoes. Even when well developed, this cuticular layer is always extremely thin. In the ostrich and in rhea it is hard and brittle, like the glaze of pottery; in the common fowl and turkey it is parchment-like; in auks and apparently in gulls it is absent. The cuticle is spread over the whole surface of the egg and into the pits or surface ends of the air canals, which are therefore closed when such a cuticle is present. The latter, however, readily admits the passage of air when dry, but when wet or moist is impermeable to air." The very great differences observable in the surface of eggs, from rough and pitted to enameled or polished or translucently brilliant, is due to the varying crystalline structure of the shell. This has been very thoroughly worked out by German microscopists, whose extensive investigations are recorded in the *Journal für Ornithologie* for 1871 and subsequently, and who have shown that a

well-defined type of shell structure belongs to each of various groups. Further information is given in the *Zoologischer Anzeiger* (1885-87).

The porosity of the shell is needful, of course, in order to admit air to the embryo; and the pores are large enough to admit also some bacteria, so that after a short time eggs not energized by vital processes become corrupt and rotten. The various preservative processes that have been attempted to prevent decay depend for their success upon the complete exclusion of bacteria and only succeed when they are begun before any infection has been received and when they absolutely close all the pores of the shell. This can best be done by soaking in limewater, in effect reinforcing and completing the natural shell.

Number and Size of Eggs. The number of eggs that constitute a clutch, or set, is fairly uniform with each species, but differs greatly among different species. Pelagic waterfowl and the larger birds of prey usually lay only one egg, rarely more than two; many game birds and lake and river fowl lay a dozen; woodland and field birds average five, though in some species two or three are prevailing numbers, and in others, e.g., titmice, the clutch may consist of 10 eggs. The number of eggs laid, except in cases correlated with peculiar circumstances in life history, are so nearly constant among species of similar habit and bear so evident a relation to the average comparative danger to which the species is exposed that naturalists recognize evidences of a seeming general principle which governs the size of the brood, and, if any peculiarity should appear in the nesting or the rearing habits that might accrue to the welfare of the individual species, it is offset by a reduced reproductive power.

Another noteworthy fact is that great diversity exists in the size and weight of eggs as compared with the size and weight of the mother bird. Hewitson states, e.g., that the raven and guillemot are of about equal size, but their eggs vary as four to one, the latter's being as big as those of an eagle. Still more remarkable for disproportionate bigness are the eggs of the Australian mound birds, which measure $3\frac{1}{4}$ by $2\frac{1}{2}$ inches, though the hen is only about the size of a common fowl; and of the extinct moas, epiornis, and the existing kiwis (*Apteryx*), that of one of the kiwis weighing nearly one-fourth as much as the hen which produces it. Much individual variation exists, and several factors seem to enter into the explanation; but in general eggs much larger than ordinary, relatively to the size of the mother, belong to birds whose precocial young will receive little or no help and care from their parents after birth, and hence must remain within the protection of the egg until they are considerably advanced towards maturity. This requires a very much larger egg

TYPES OF EGGS OF AMERICAN SONG BIRDS.

1. Flycatcher, olive-sided.
2. Flycatcher, vermilion.
3. Flicker, golden-backed.
4. Sparrow, Henslow's.
5. Flycatcher, scissor-tailed.
6. Oriole, orchard.
7. Phoebe, Say's.

FOR NAMES AND DESCRIPTIONS SEE TEXT.

than is needed for the early-born, parent-supported, altricial birds, since a much greater quantity of food (yolk) must be stored up for them, and they must have room to grow. It is plain that few such eggs can be produced from the resources of the mother's organization, and, as a matter of fact, these huge eggs are laid singly; as a rule, relatively large eggs mean few in a brood.

Shape. In shape birds' eggs are rarely spherical, though the contained yolk is always so, but ordinarily are ovoid, being much larger at one end than the other, and often nearly conical; while some are oblong, having a decided length but no excess of thickness at either end. Eggs laid in holes or deep, cuplike nests, where they cannot fall out, are likely to be spherical or ovoid; while those laid upon the ground, with little or no nest, are usually conoid, and likely to be large for the size of the bird. This shape gives them two advantages: first, it enables them to lie more closely together, the points towards a common centre, so that they are easily covered by the brooding bird; and, second, in the case of eggs, like those of guillemots, which are laid upon bare ledges of sea cliffs with no encircling nest, the conical shape prevents their being easily rolled or blown away when uncovered, because when moved they will tend to gyrate upon their points and not roll away. Among the services which the eggshell performs, the foremost is the protection of the embryo from injurious changes of temperature and from too much light. See GROWTH.

Color. Birds' eggs may be said to be normally chalky white, but in a great number of groups they are colored. The color may be a uniform tint over the whole surface, or a tint with markings; or simply dots, spots, streaks, or blotches of one or more hues on an otherwise colorless shell. These colors exude from uterine glands in the form of pigment corpuscles deposited with the forming shell and stain its deeper as well as its more external layers. Many of the variations in tint of the spots are thus due simply to their being overlaid by more or less transparent material, but certain real colors exist. This matter was studied by H. C. Sorby by the methods of spectrum analysis described by him in the *Proceedings of the Zoological Society of London* for 1875. He learned that the coloring matter in eggshells are connected with hæmoglobin and the bile pigments and are definite physiological products. He reported seven of these products as follows:

1. *Oörhodeine*. The most important of the colors, present in almost all eggs, which gives an effect when alone of brownish red. The spectroscopic shows so close a similarity between this and the product of the decomposition of the red corpuscles of the blood as to make it probable that they are physiologically identical and derived from the same source. Such red-brown eggs as those of the grouse are mainly tinted by this material.

2. *Oöcyan*. A fine blue.

3. *Banded oöcyan*. Also a fine blue, but giving a different spectrum. A chemical similarity is apparent between the two oöcyans and the pigments of the bile; and they must be regarded as derived by separate physiological processes from the same source.

4. *Yellow oöxanthine*. Clear yellow; unstable and liable to fade.

5. *Rufous oöxanthine*. Reddish yellow.

6. *A substance giving narrow absorption bands in the red*. Probably brown.

7. *Lichenoxanthine*. A brick-red substance, apparently identical with a coloring matter common in plants, especially in lichens and fungi.

The mixture of these pigments in various ways gives the varied colors observed in eggshells. Thus, the nightjar's egg has been shown to be colored with a mixture of oörhodeine and oöcyan; while all the varying greens and blues so common as ground tints are due to varying mixtures of oöcyan with oöxanthine, and such are likely to fade or to change color when long exposed to the light.

An interesting feature in this connection is that not only the state of health, but the state of mind of a bird, may affect the colors of its eggs, as Hewitson long ago recorded.

Theories of Color-Markings on Eggs. The reason for the many and various colorings of birds' eggs has been a favorite field of speculation and many ingenious theories have been constructed to explain the matter, from the pious musings of Sir Thomas Browne to the present day. The most important thesis is that advanced by Wallace and enlarged by Poulton, who attempt to show that birds' eggs are examples of protective mimicry in color, as the result of natural selection. Impartial examination shows, however, that only in a minority of cases does the theory of adaptive coloration seem to be adequate and not open to serious interference from other explanations or contradictions: such favorable cases are those of the nightjars, game birds, shore birds, coots, and some other ground builders making scanty nests, whose eggs certainly do closely simulate the beach, or leaves, or marsh grass upon which they lie. They are certainly very difficult to see, especially for human eyes; but most of the despoilers of birds' nests are not human, but brute foes which, for the most part, depend less upon their eyes than upon their noses to discover what they seek, and most of which go about by night rather than by day. Against such foes color is of small importance among the factors of safety. It is quite probable that in the cases above mentioned the inconspicuous coloring of the eggs is of some consequence, and may be the result in some degree of natural selection; but these cases are only a small part of the whole array of bird life, and "protective coloration" certainly fails as yet to account for the coloring of birds' eggs as a whole.

It is much more likely that this phenomenon falls under the theory of "recognition" colors. Many facts go to show that birds recognize their own eggs, and the supposition is reasonable that the tints and markings, if they serve any useful purpose at all, serve that of identification by their owners. This would account for the fact that eggs laid in dark holes are usually white; and it would explain the individual variation within the limits of specific or tribal likeness which universally characterizes the eggs of birds.

Utilization of Birds' Eggs. Eggs being intended not only for the production of new beings, but for their nutrition during the embryonic period, mainly consist of a store of highly nutritious material, which is as good food for other animals as for the young birds. Hence all eggs may be called edible, though some are so impregnated with a fishy or musky flavor or odor as to be unpalatable to civilized mankind. The vast use made of the eggs of do-

mestic fowls as food and in the arts is elucidated in another article (see EGG AS A FOOD), but attention may be called here to the fact that in many parts of the world the gathering of the eggs of birds, mainly sea birds, which nest in vast communities, is a regular industry furnishing an important part of the food of the local population. This is especially true of high northern regions. In some of the islands of the Pacific eggs of the fowl are gathered by thousands, but the eggs of the fowl are not them commercial albumen; but this industry is diminishing by reason of the steady depletion of the numbers of the sea fowl thus disturbed and robbed. The making of collections of eggshells for scientific museums, and still more for the satisfaction of private curiosity and ambition, has long been an industry in which much money is annually expended, rare eggs often commanding very high prices, the few eggs remaining of the extinct great auk (q.v.) being worth at present more than \$2000 each. Lastly it is to be mentioned that in the season when birds are breeding, their eggs and fledglings form an important part of the food of many other animals.

Mammalian Eggs. The eggs of all the mammals except the monotremes (q.v.) are minute globules (that of human beings being only about $\frac{1}{100}$ of an inch in diameter), containing a little yolk, which pass through all the stages of development within the body of the mother. (See EMBRYOLOGY.) The two groups of monotremes, the duckbills and echidnas (q.v.), however, are ovoviviparous, that is, they produce eggs which are voided from the mother and developed outside her body. These eggs are very much larger than those of other mammals, because they must carry a comparatively large amount of yolk food. Those of the duckbill, two in number annually, are globular, about three-fourths of an inch in diameter, and have a tough yellow calcareous shell; they are deposited in a soft nest in the animal's burrow and hatch there. The echidna produces one egg a year, one-half to three-fourths of an inch in diameter, and covered with a horny envelope (keratin), which is placed as soon as voided in a mammary pouch and there completes its development.

Eggs of Reptiles and Amphibians. Most reptiles are oviparous, laying eggs, either globular or oblong in shape, closely resembling birds' eggs in composition of yolk, albumen, and coverings, except that the shell is not calcareous, but of a tough, yellowish-white, parchment-like (coriaceous) material. "These are usually deposited in holes and left to hatch by the heat of the sun. In the case of the crocodiles they are deposited in a rough nest and guarded by the mother. In all cases development has only progressed to a very early stage when the deposition of the eggs takes place, and it is only after a more or less prolonged period of incubation that the young, fully formed in every respect, emerge from the shell and shift for themselves." These eggs are most numerous in the case of the turtles, numbering from 25 to 250, and are buried in the sand of sea beaches and river banks. Those of the fresh-water species are mostly numerous, but the eggs of sea turtles are excellent food, will keep fresh a long time, and are extensively gathered, the people of many tropical countries subsisting largely upon them in their season. They are also much fed upon by wild animals. Many lizards and serpents do not lay eggs, but are viviparous; but the pythons not

only lay them but incubate them within the circle of their coiled bodies.

The Eggs of the Amphibians. These differ from eggs of reptiles in being small, numerous, having comparatively little yolk, and are usually laid in the water inclosed in gelatinous masses or cords. Sometimes they float or lie upon the bottom, are attached to submerged plants, or are laid under logs or stones; and in a few cases they are carried about by one or the other parent until they hatch, or the mother coils about them in an underground cell. They are devoured by some aquatic animals. In some forms the eggs hatch before extrusion, thus resulting in viviparity. See MIDWIFE FROG.

Eggs of Fishes. The fishes may be broadly divided into "cartilaginous" and "bony," which differ essentially in respect to their eggs. The cartilaginous fishes—sharks, rays, etc. (q.v.)—which are not viviparous, produce in each case only a few eggs, which are nearly as large as those of bony fishes, which, like these, are inclosed in a tough, gelatinous case and contain much yolk and albumen. Some species are viviparous. In those which extrude their ova in a more or less advanced stage of development each egg is covered by a dark-brown chitinous case, which most commonly is flat and four-cornered, with twisted filamentous appendages at the corners, by means of which it becomes attached to seaweeds and the like. These are the "sea purses" of fishermen.

The bony fishes mostly emit minute eggs, usually called "spawn," in vast quantities, a number of sea fish producing two or three hundred thousand. The extremes are the sturgeon, which may produce 7,000,000, and the turbot, which may actually deposit twice that number. These are cast into the water and contribute a large part of the food supply of aquatic creatures, nineteen-twentieths, probably, being quickly devoured. Some float at or near the surface; others sink to the bottom. Some fresh-water fishes, however, deposit their eggs in prepared nests, where they are guarded and attended until they hatch. (See NIDIFICATION.) This reduces the proportion of loss so greatly that comparatively few need be produced, and they are far larger, relatively, than in the other case. The eggs of such fishes as the shad, under the name of "roe," and of the sturgeon (caviar), enter largely into the list of human comestibles.

Eggs of Insects. Eggs and their development among the insects present a great number of interesting phenomena, of which only a sketch may be given here. In many cases in this class the eggs are so carefully placed as to insure the survival of almost every one, and in proportion as the precautions are complete the number periodically laid is diminished; in fact, in nearly all cases, except in the Hymenoptera, each egg, or else a group of eggs, is within a strong shell or capsule.

Bees, wasps, and ants lay relatively large, elliptical, shell-less eggs, usually each by itself, in the cells of their combs or burrows, placing with them food for the expected larvæ (honey, beebread, palsied spiders, etc.). Other insects

place them within or upon the bodies of other insects, as is the habit of the parasite ichneumons and chalcids; or insert them into plant tissues and wood, as do the gallflies, sawflies, etc. Many flies produce living larvæ and others retain their eggs until nearly mature. The bottle-shaped eggs of mosquitoes stick together in a sort of cake or raft that floats on the surface of water; those of the midges are imbedded in jelly, which swells in the water and sticks to a support; the buffalo gnats glue theirs in large patches of submerged rocks. The snipe flies, gadflies, and some others put their eggs on dried branches overhanging the water, sometimes in large pear-shaped masses to which several females contribute, and many others force theirs into the ground or into decaying wood or dung, carrion meat, or wounds, as is the case with house flies, flesh flies, syrphus flies, etc.; while the bots attach theirs to animal hairs, where they may be licked off and develop in the stomach of their host. It is clearly impossible to carry this particular description through the list. One of the longest as well as most entertaining chapters in the admirable *Introduction to Entomology*, by Kirby and Spence, is filled with such details. An excellent summary has been made by Carpenter as follows:

"The outer form of insects' eggs is exceedingly variable. Very many—as those of beetles, grasshoppers, and flies—are elongate, like the cockroaches. The eggs of some moths are globular, while those of butterflies, and especially those of the hawk moth, are useful, flasklike shapes and elongated surfaces. Other insects—the golden-eye flies, for example—produce stalked eggs, which are raised well above the plant stem on which they are laid, and so protected from mites and other enemies. Insect eggs contain a quantity of food yolk, and are therefore of comparatively large size. The globular egg of the hawk moth, for instance, measures $\frac{1}{10}$ inch in diameter, while the similarly shaped egg of a cat measures only $\frac{1}{100}$ inch. The cockroach's eggs are protected by a purse-shaped capsule. Sixteen eggs are contained in this case, eight on a side. . . . Many insects protect their eggs by a gummy secretion; some female moths shed hairs from their bodies to afford the eggs a covering. Those of the water insects are often contained in a long gelatinous tube, and some water beetles construct around their eggs a silken cocoon. Locusts, grasshoppers, and many other insects bury their eggs in the ground for safety; other insects, chafers and crane flies, for example, lay their eggs in the ground that the young may be near the roots of plants on which they will feed. Almost universally the food of the young determines the place of egg laying."

It is an interesting fact that in elliptical eggs of insects the forms of the larvæ or adult, i.e., their dorsal, ventral, and lateral surfaces, are foreshadowed in the shape of the egg. See ANT; BEE; WASP.

Eggs of Crustacea. Some crustaceans produce masses of agglutinated eggs, which the female carries about with her, attached to her abdominal appendages, until they hatch. Others lay comparatively few eggs, which are carried about by the female in one or two special sacs; while many simply set their numerous small eggs free in the water.

Eggs of the Lower Invertebrates. The eggs of the squids and other cephalopod mollusks are enveloped in a tough viscid membrane, and stick

together in masses, called "sea grapes," which adhere to some fixed object. They contain much food yolk, and the young are well advanced before leaving the shell. Among the ordinary univalved and bivalved mollusks a greater variety in respect to eggs is to be met with than might be expected. The bivalves (*Pelecypoda*) pour out immense quantities of minute eggs and spermatozoa into the water, to meet if they can. A large proportion of this will be wasted, but a still larger proportion (with the floating eggs of other low marine creatures) serves a very useful purpose in supplying food to the hosts of fixed creatures (polyps, sea anemones, other mollusks, etc.), which can obtain food only as it is brought to them by currents of water, and must trust largely to floating eggs and young. Only a very small percentage is fertilized, and a still smaller part ever matures. An exception is afforded by the fresh-water mussels, which keep their eggs within their shells, inclosed within the gills and mantle, and so protect them. Among gastropods the eggs are comparatively few and well cared for. "In almost all the Gastropoda," say Parker and Haswell, "fertilization is internal, and the eggs are laid in great masses imbedded in jelly—each egg having its own hyaline envelope. Very often the mass of spawn, consisting of the jelly-like substance, with the eggs imbedded in it, attains a relatively considerable size. In form it varies greatly; very often it is in the shape of long strings, which are cylindrical or bandlike; sometimes several such strings are twisted together into a cord. Sometimes the spawn is fixed to seaweed or other objects; sometimes it is unattached and may float about freely. In the Streptoneura, instead of a jelly-like mass, the eggs are inclosed in a firm parchment-like capsule, in which is contained, in addition to the eggs, a quantity of an albuminous fluid, serving to nourish the developing embryos. . . . Very commonly large numbers of these capsules are aggregated together, and usually they are attached to a rock or a seaweed or similar object. . . . In the land Pulmonata (snails) each ovum is sometimes imbedded in gelatinous matter inclosed in a firmer envelope, and a number of them are arranged in a string; sometimes a larger number are imbedded in a rounded gelatinous mass. Usually, as in *Helix* and other genera, the outer layers of the albumen-like substance inclosing the eggs become toughened and impregnated with salts of lime, so as to assume the character of a calcareous shell."

The **Annelids** (*Annulata*) have comparatively large ova, and each has a double gelatinous envelope and contains food yolk; some cast them abroad; by many they are inclosed in packets or cocoons (as is the case in the earthworm), or stick together or to the parent or to some outside object. The egg of the flatworms has a protective chitinous integument, contains food yolk, and sometimes (as among mollusks, insects, etc.) has an operculum facilitating the escape of the matured embryo; also external cement for attachment to other eggs or to some fixed object. The same is true of nematodes, which oviposit vast numbers of eggs—15,000 a day, it is stated. The Trochelminthes (rotifers) lay eggs of three kinds, those produced in the autumn having thick shells to enable them to survive the winter and develop in the spring. Polyzoans and brachiopods produce very few eggs at a time, and these are developed into larvæ in "brood pouches" within

the body. The eggs of echinoderms are minute globules, consisting of germ cell, food yolk, and a glassy exterior layer. They are generally set free in the water, where they are fertilized and developed. Sometimes they stick to the surface upon which they are laid and develop there. The eggs of coelenterates and sponges are hardly worthy of the name, being merely microscopic germ cells, set free in vast quantities as one of several means of reproduction.

EGG. In plants, the more technical term for the egg is "oosphere." Among the lowest plants in which sexuality is developed, such as the lower algæ and fungi, the two sex cells (gametes) do not differ in appearance, a condition which is called "isogamy." Most plants, however, are not isogamous, their pairing gametes being very dissimilar. The male gamete, called the sperm, is small and usually motile by means of cilia; while the female gamete, called the egg, is

ture called the "archegonium," in whose venter (the bulbous part) the egg is organized; while among spermatophytes (seed plants) there is no female organ, the egg appearing as a free cell in the embryo sac which is embedded in the ovule. In most cases a solitary egg is formed by a sex organ, in which it passively remains till fertilized by the spore, but there are some interesting exceptions. For example, in the common rockweed (*Fucus*), a brown alga of the sea-shore, some of the species have oögonia which produce eight eggs that are discharged into the water for fertilization. Under ordinary circumstances, an egg must unite with a sperm, that is, it must be fertilized before it can accomplish anything. The new cell thus formed by the fusion of two cells is known as the "oöspore" or "fertilized egg." Occasionally, however, an unfertilized egg may produce a new plant, the phenomenon being known as "parthenogenesis." Parthenogenesis is rather common among the lower plants, and it is not entirely unknown even among seed plants, although its occurrence there has been reported in relatively few forms. See EMBRYO; CELL; CYTOLOGY; SPERM; PARTHENOGENESIS; FERTILIZATION; OÖGONIUM; OÖSPORE.

EGG. As a food, perhaps no article of animal origin is more common in all countries or served in a greater variety of ways. Hens' eggs are most popular, although the eggs of ducks, geese, and guinea fowls are used to some extent. More rarely turkeys' eggs are eaten, but they are generally of greater value for hatching. The eggs of the lapwing (q.v.), called "plover eggs," are prized in England and Germany, while the eggs of sea birds have long been gathered for food. Other eggs besides those of birds are sometimes eaten. Turtle eggs are highly prized in most countries where they are abundant. The eggs of the terrapin are usually served with the flesh. Fish eggs, especially those of the sturgeon, under the name of caviar (q.v.), are eaten in large quantities, preserved with salt. Shad roe is also a familiar example of the use of fish eggs as food. Mention may also be made of the use by some races of the eggs of alligators, lizards, serpents, and various insects.

Cooking of Eggs. The methods of serving alone, or in combination with other food materials, are very numerous. Cooked in various ways they are a favorite animal food, taking the place of meat to a certain extent, while raw eggs, usually seasoned in some way, are by no means infrequently eaten. Boiled eggs are often used for garnishing or ornamenting different foods. Eggs are combined with other materials in various ways in many made dishes. They are used in making cakes and such foods to improve the flavor, color, and texture, while in custards, creams, etc., they thicken the material and give it the desired consistency. The white of the egg is employed in making icings and confectionery. Well-beaten egg white incloses air in small bubbles, which in mixing become distributed throughout the mass of dough of cakes and similar foods. The heat of cooking expands the bubbles, which become firm; the porous structure is retained, thus improving both the texture and flavor of the product. The power of eggs to inclose and retain air, when beaten, varies, being greatest in the fresh egg and much less in packed or old eggs. There are several simple ways of cooking eggs which are very commonly followed. Thus, the egg in the shell is cooked by immer-

EGG:
a, of fern; b, of liverwort.

relatively large and passive. Plants with such dissimilar gametes are said to be "heterogamous." Both sperms and eggs are single, naked cells, but the former are characterized by their activity, the latter by their food supply. As in all living cells, the egg consists of a nucleus invested by more or less cytoplasm, in this case the cytoplasm being conspicuous in amount and containing an abundance of reserve food. Usually a special organ is set apart to develop within itself a single egg. Among algæ and fungi this female organ is generally a single spherical cell, and is called the "oögonium"; among the bryophytes (mosses and their allies), pteridophytes (ferns and their allies), and gymnosperms (conifers and their allies), the female organ is a many-celled, flask-shaped struc-

sion in hot or boiling water, or is less commonly roasted; or, after removal from the shell, the egg is cooked in hot water or in hot fat. In the latter case it may or may not be beaten or stirred. Combined with other materials to form variously made dishes, eggs are boiled, baked, steamed, or fried, as the case may be. The total number of methods of serving and preparing eggs is very large, but in nearly every case it will be found that the method of preparation is only a more or less elaborate modification of one of the simple methods of cooking. When cooked in different ways there are marked changes in the appearance and structure of eggs. If the egg white is gently warmed no change is noticed until the temperature reaches 134° F., when coagulation begins. White fibres appear, which become more numerous, until at about 160° F. the whole mass is coagulated, the white almost opaque, yet tender and jelly-like. If the temperature is raised and continued to 212° F. (the temperature of boiling water), the coagulated albumen becomes much harder, and eventually more or less tough and hornlike; it also undergoes shrinkage. When the whole egg is cooked in boiling water the temperature of the interior does not immediately reach 212° F., several minutes being probably required. The yolk of egg coagulates firmly at a lower temperature than the white. The fact that egg white becomes hard and contracts when heated for some time, at the temperature of boiling water, explains the curdling of custards, shrinkage and toughening of omelets, soufflés, me-ringues, sponge cake, and similar mixtures. The firm coagulation of albumen at 212° F. explains the use of egg white for clarifying coffee, soup, or other liquids. The albumen, which is mixed

shells. Large quantities of egg white are used for other purposes than for food, such as for manufacturing photographic papers; the yolks also are utilized in the arts.

Characteristics and Composition. The eggs of different kinds of domestic poultry vary in size, as well as appearance, and there is also a considerable range in the size of eggs of different breeds. On an average, a hen's egg is 2.27 inches in length and 1.72 inches in diameter, or width, at the broadest point, and weighs about 2 ounces, or eight eggs to the pound (1½ pounds per dozen). Generally speaking, the eggs of pullets are smaller than those of old hens, those of ducks somewhat larger than hens' eggs, while those of turkeys and geese are considerably larger. Guinea eggs, on an average, measure 1⅞ by 1½ inches, are rather pointed at one end, and weigh about 1.4 ounces each, or 17 ounces to the dozen. Goose eggs weigh about 5.5 to 6.7 ounces each, or about 5 pounds to the dozen, i.e., more than three times as much as hens' eggs. The eggs of wild birds are said to be smaller than those of the same species when domesticated. Wild ducks' eggs are, on an average, 1.97 to 2.17 inches in diameter; domestic ducks' eggs, 2.36 to 2.56 inches. The shells of hens' eggs constitute about 11 per cent, the yolk 32 per cent, and the white 57 per cent of the total weight of the egg. White-shelled eggs have a somewhat heavier shell than brown-shelled eggs. The shell of a duck's egg constitutes about 14 per cent of the total weight and that of a plover's egg 10 per cent. The following table shows the composition of the eggs of poultry and the plover, and, for comparison, that of evaporated hens' eggs, egg substitute, and pudding powder:

TABLE SHOWING AVERAGE COMPOSITION OF EGGS AND EGG PRODUCTS

	Water	Protein	Fat	Carbohydrates	Ash	Fuel value per pound
	Per cent	Per cent	Per cent	Per cent	Per cent	Calories
Hen:				See following paragraph.		
Whole egg, edible portion.....	73.7	13.4	10.5		1.0	720
White.....	86.2	12.3	0.2		0.6	250
Yolk.....	49.5	15.7	33.3		1.1	1705
Duck:						
Whole egg, edible portion.....	70.5	13.3	14.5		1.0	860

with the liquid before boiling, coagulates and incloses the floating particles, leaving the liquor clear. When eggs are removed from the shell, a little of the white, unless scraped off, usually clings to the inner surface. Such eggshells are often used for clarifying purposes, instead of the whole egg. The clarifying properties are, of course, due to the egg white, and not to the

Eggs consist chiefly of two nutrients—protein and fat—in addition to water and mineral matter or ash. Carbohydrates are present in such small amounts that they are usually neglected in the analysis. The results of numerous analyses show that there is practically no difference in composition between hens' eggs with dark shells and those with white shells, although

there is a popular belief that the former are "richer." In general, it may be said that eggs are nutritious food. They are less concentrated, i.e., contain more water, than cheese, but are more concentrated than milk or oysters. In water content they do not differ greatly from the average value for lean meat. The kinds and amounts of nutrients in eggs indicate that they may be properly used in the diet in the same way as most other animal foods, and this belief is confirmed by experience.

Food Value. Eggs which are perfectly fresh have the finest flavor. After eggs have been kept for a time the flavor deteriorates, even if there be no indication of spoiling. Such differences are especially important when eggs are used for table purposes. Stale eggs are regarded as not palatable, and the flavor of spoiled eggs is such that because of it, if for no other reason, they are totally unfit for food. The flavor of even perfectly fresh eggs is not always satisfactory, since it is influenced more or less by the character of the food eaten by the laying hens, onions and some other highly flavored feeds imparting an unpleasant flavor to the eggs. The flavor is also impaired when the air in which the eggs are stored is tainted by odors such as those of decaying vegetables, rancid fats, and gases of various kinds.

Raw eggs or eggs only slightly cooked are commonly said to be very indigestible, the idea being obviously that they digest readily without giving rise to pain or other physical discomfort. This is in accord with the results of numerous experiments, which show that the length of time that eggs are cooked affects somewhat the time required for digestion, and that some 95 per cent of the total dry matter, 97 per cent of the protein, and 95 per cent of the fat of eggs is digestible. It seems fair to conclude that the length of time of cooking has less effect upon the percentage amount that may be digested than upon the time required for digestion. In a healthy man, the latter consideration is probably not a matter of much importance; in the diet of sick persons and invalids it may be more important. In the average of several hundred dietary studies in American families eggs furnished 2 per cent of the total food, 4 per cent of the total protein, and 3 per cent of the total fat used per man per day. In this respect, eggs compare favorably with the more common animal foods.

Marketing and Testing. In earlier times eggs, if sold at all, were marketed near the place where they were produced. Many are still sold in local markets; but with improved methods of transportation the market has been extended, and eggs may be shipped to far-distant points. For shipping long distances, there are special egg cases. Eggs which are to be shipped, whether with or without a special attempt at preservation, should be perfectly fresh, and should never be packed in any material which has a disagreeable odor. Microorganisms enter the egg through the minute pores in the shell, and set up fermentation, which ruins the egg. In other words, it becomes rotten. The unpleasant odor of rotten eggs is due to the formation of sulphureted hydrogen. The normal eggshell has a natural surface coating of mucilaginous matter, which hinders the entrance of these harmful organisms for a considerable time. If this coating be removed or softened by washing or otherwise, the keeping quality

of the egg is much diminished. If the process of hatching has begun, the flavor of the egg is also injured. There are many ways of testing the freshness of eggs which are more or less satisfactory. "Candling" is one of the methods most commonly followed. The eggs, when held against a light in a suitable device, appear unclouded and almost translucent when fresh, and dark colored if they are added. A dark spot may be observed if incubation has begun, which increases in size according to the stage to which incubation has advanced. The age of eggs may be approximately judged by taking the fact that, as they grow old, the freshness decreases through evaporation of moisture. According to Siebel, a new-laid egg placed in a vessel of brine made in the proportion of two ounces of salt to one pint of water will at once sink to the bottom. An egg one day old will sink below the surface, but not to the bottom, while one three days old will swim just immersed in the liquid. If more than three days old, the egg will float on the surface, the amount of shell exposed increasing with age; and if two weeks old, only a little of the shell will dip in the liquid. The humidity of the atmosphere in which the eggs were kept would doubtless influence the results.

Methods of Preservation. Fresh eggs are preserved in a number of ways, which may, for convenience, be grouped under two general classes, which are often combined: (1) Use of low temperature, i.e., cold storage; and (2) exclusion of air, i.e., coating, covering, or immersing the eggs, some material or solution being used which may or may not be a germicide. The first method owes its value to the fact that microorganisms, like larger forms of plant life, will not grow below a certain temperature, the necessary degree of cold varying with the species. It is stated by Siebel that, in practice in the United States, 32° to 33° F. is regarded as the best temperature for storing eggs, although some American packers prefer 31° to 34°. English writers recommend a temperature of 40° to 45° as being equally effective. Without doubt the amount of moisture in the air in the cold-storage chamber has an important bearing on this point. Eggs are generally placed in cold storage in April and the early part of May; if later than this time they do not keep well. They are seldom kept in storage longer than a year. Eggs which have been stored at a temperature of 30° must be used soon after removal from storage, while those stored at 35° to 40° will keep for a considerable time after removal from storage, and are said to have the flavor of fresh eggs. Stored eggs should be turned at least twice a week, to prevent the yolk from adhering to the shell. Eggs are sometimes removed from the shells and stored in bulk, usually on a commercial scale in cans containing about fifty pounds each. The temperature recommended is about 30° F. a little below freezing, and it is said they will keep any desired length of time. They must be used soon after they have been removed from storage and have been thawed. The substances suggested and the methods tried for excluding air conveying microorganisms into the egg, and for killing those already present, are very numerous. An old domestic method is to pack the eggs in oats or bran. Another, which has always had many advocates, consists in covering the eggs with limewater, which may or

may not contain salt. The results obtained by such methods are not by any means uniform. Sometimes the eggs remain fresh and of good flavor, and at other times they spoil. A method of preserving eggs, which has recently been often used with much success, consists in packing them in carefully cleaned vessels of suitable shape, and covering them with a 10 per cent solution of water-glass (sodium silicate or potassium silicate). The shells of eggs preserved in water glass are apt to crack in boiling, but, it is stated, this may be prevented by puncturing the blunt end of the egg with a pin before putting it into the water. In the East Indian Archipelago salted ducks' eggs are an article of diet, the new-laid eggs having been packed for two or three weeks in a mixture of clay, brick dust, and salt. They are eaten hard-boiled. In that region and in India, turtle eggs are also preserved in salt. These products, while unusual, do not necessarily suggest an unpleasant article of diet. The same can hardly be said of a Chinese product which has often been described. Ducks' eggs are buried in the ground for 10 or 12 months and undergo a peculiar fermentation. The hydrogen sulphide formed breaks the shell and escapes, while the egg becomes hard in texture. The final product, it is said, does not possess a disagreeable odor or taste.

Diseases Caused by Egg Eating. Some persons are habitually made ill by eating eggs, just as there are those who cannot eat strawberries or other food without distress. Such cases are due to some personal idiosyncrasy. Overindulgence in eggs, as is the case with other foods, may induce indigestion or other bad effects. Furthermore, under certain conditions, eggs may be the cause of illness by communicating some bacterial disease or some parasite. It is possible for an egg to become infected with microorganisms before it is laid as well as after. The shell is porous and offers no greater resistance to microorganisms which cause disease than it does to those which cause the egg to spoil. If the infected egg be eaten raw, the microorganisms present may gain entrance to the tissues and cause disease. Judged by the comparatively small number of cases of infection or poisoning due to eggs reported in medical literature, the danger of disease from this source is not very great. However, in view of its possibility, it is best to keep eggs as clean as possible, to reject or thoroughly cook doubtful ones, and thus endeavor to prevent infection.

Commercial Importance. The egg industry is of considerable commercial importance. The total number of eggs produced on farms in the United States in 1909 was estimated by the census bureau at 1,591,311,000 dozen, or 17 dozen per capita of the population; and their value at \$306,689,000.

Egg Powders, Desiccated Eggs, and Egg Substitutes. Several methods of evaporating or desiccating eggs have been proposed, and products which claim to be prepared in these ways are now on the market. The egg is dried in or out of a vacuum, usually by a gentle heat or by currents of air. Before being placed on the market the material is usually ground. Sometimes salt and sugar are used as preservatives. As will be seen by reference to the above table of composition, such products are merely eggs from which the bulk of water has been removed. If the process of manufacture be such

that the resulting product is palatable and keeps well, the value of evaporated eggs for many purposes is evident. This material is used by bakers to some extent, as being cheaper, when fresh eggs are high in price. Since, if all the water be removed in preparing evaporated eggs, one pound of the dried product will furnish material equivalent to about four pounds of fresh eggs, and since desiccated foods have the advantage over the fresh substances of reduced bulk, evaporated eggs are used in provisioning for land and expeditions.

There have been devised which consist of mixtures of animal or vegetable fats, albumen, starch or flour, coloring matter, and some leavening powder in addition to the mineral matters similar to those found in the egg. Such products are designed to resemble eggs in composition. One has been manufactured from skim milk containing the casein and albumen of the milk, mixed with a little flour. It is put up in the form of a paste or powder. Other egg substitutes have been marketed which contain little or no albumen, but which apparently consist quite largely of starch, more or less colored, with some yellow substance. These goods, sometimes called "custard powder," are specially recommended for making custards and puddings similar in appearance to those in which fresh eggs are used. There is no reason to suppose that such products cannot be made so that they will be wholesome and perfectly harmless; but the fact must not be overlooked that in the diet they cannot replace fresh eggs, since they do not contain much nitrogenous matter or fat. This may be an important matter if such an egg substitute be used in the diet of invalids, especially if the composition of the egg substitute is not known, and it be employed with the belief that, like eggs, it contains an abundance of protein.

EGG, or EIGG. An island of the Inner Hebrides (q.v.) group, 12 miles off the west coast of Inverness-shire, Scotland, and 8 miles southwest of Sleat Point in Skye (Map: Scotland, B 3). It is about $6\frac{1}{2}$ miles long and terminates on the southwest in the remarkable Scur of Egg, which rises to 1346 feet. The upper 470 feet of this hill is a mass or vein of pitchstone. Some of the pitchstone forms straight, inclined, or curved columns, which vary in diameter from a few inches to nearly 2 feet. In the south part of the island is a large cave, entered by a narrow opening, through which but one person can creep at a time. Here, in the sixteenth century, a feudal laird of Macleod, to revenge an injury done to some of his clan, smoked to death all of the inhabitants (200 Macdonalds) of the island, who had hidden themselves in the cave. Pop., 250.

EGG, AUGUSTUS TROPION (1816-63). An English genre painter. He was born in London and studied under Sass and at the Royal Academy. He painted chiefly genre pictures and, like Leslie and Newton, chose his subjects from literature and history. His pictures show a greater feeling for color than Leslie's, but are without his humor, and in a scene from "Le Diable Boiteux" (1844, National Gallery) he shows an execution superior to Newton's. The influence of the Pre-Raphaelites is traced in "Peppys's Introduction to Nell Gwynne" (1851). Among other noteworthy paintings are: "Peter the Great Sees Catharine for the First Time" (1850); "The Knighting of Esmond" (1851).

Gallery, London); and "Katherine and Pe-fruchio" (1860). In 1860 Egg became a Royal Academician.

EG'GA. A town of Nupé, in British Nigeria, West Africa, situated on the right bank of the Niger. Its commerce is very important and it has a considerable transient population. The inhabitants, who number about 15,000, are chiefly engaged in trade.

EGG-AND-DART. A motive of ornament commonly decorating a convex molding or ovolo (q.v.), and consisting of an egg-shaped solid (*ôve*) set in a frame, or "shell," with a tongue, dart, or arrow between each pair of shells. It is allied to the bead-and-reel and water-leaf ornaments, was first used in Greek art as a painted motive on vase lips and architectural moldings, and was later carved on moldings of the Ionic order. It is common in Roman, Renaissance, and modern art, and occurs sometimes in mediæval art. See **MOLDING**.

EGG APPARATUS. A group of three cells in the embryo sac of Angiosperms. One of the cells is the egg, and the two others are synergids, whose name suggests that they are of service in connection with the fertilization of the egg.

EGGAR MOTH. See **EGGER MOTH**.

EGG BIRD. Any wild bird whose eggs are regularly sought as food by mankind; especially, a gull or tern and, in particular, the sooty tern. See **TERN**.

EGG COCKLE. The common edible cockle of Europe. See **COCKLE**.

EGG DANCE. A very old English dance, which was probably derived from the Saxons. Eggs were placed at certain intervals on the floor, and the dancer took his position and was blindfolded. The music used was the hornpipe, and to it the performer danced back and forth between the eggs without touching them. The positions of the eggs and the figures danced seem always to have been the same. A similar feat was very popular in Holland in the seventeenth century, and the Valencians in Spain have much the same sort of a dance at the present time.

EGG-EATING SNAKE. A remarkable little colubrine serpent (*Dasypeltis scabra*) of South Africa, whose dentition and throat are specially adapted to the consumption of birds' eggs, upon which this snake mainly subsists. It is a

AN EGG-EATING SNAKE.

Appearance of the snake (*Dasypeltis scabra*), with an unbroken egg in its gullet, showing the extensibility of jaws and throat.

slender little creature, prettily variegated, and about 2 feet in length. Its mouth has no teeth, or at least a few very rudimentary ones, but has "about 30 of what may be termed throat teeth; these being the lower spines of the vertebra, which project into the œsophagus and are tipped with enamel." It lives in trees and feeds on the eggs of small birds, but, when pressed by hunger, will descend and rob hens' nests; and the elasticity of its mouth and throat is so great that it can take into them pigeons' eggs

with ease and even large fowls' eggs. When the egg is fairly within the throat, the throat teeth cut through the shell, allowing all its fluid contents to be swallowed without the loss of a drop, after which the crushed shell and membranes are ejected. An illustrated article upon examples living in the Zoological Gardens of London may be found in the *Field* (London, 1892), while a very exhaustive and illustrated treatise may be found in Fitzsimons, *Snakes of South Africa* (Cape Town, 1912).

EG'GELING, JULIUS (1842-). An English Sanskrit scholar. He was born at Hecklingen, Germany, and was educated at Breslau and Berlin (1862-66). Within a year after his graduation he went to England, where in 1869 he was appointed secretary and librarian of the Royal Asiatic Society. In 1872 he became professor of Sanskrit at University College and three years afterward was called in the same capacity to Edinburgh. His publications include: *The Catapatha-Brahmana, Translated according to the Text of the Mādhyandina School* (vols. i-v in "Sacred Books of the East," 1882-85); *Catalogue of Buddhist Sanskrit Manuscripts in the Possession of the Royal Asiatic Society*, with Cowell (1875); the article "Sanskrit Language and Literature," in the *Encyclopædia Britannica* (1887); *Catalogue of Sanskrit Manuscripts in the Library of the India Office* (7 parts, 1887-1904); and editions of *Vardhamāna's Gaṇaratnamahodadhi* (2 parts, 1879-80), the *Kātantra* (6 books, 1874-78), and of the *Koṇva Satapatha Brāhmaṇa* (1902).

EGGER, A'gar', EMILE (1813-85). A French classical scholar, born in Paris. After holding various professorships of ancient languages, he was professor of Greek literature at the Faculté des Lettres of the University of Paris from 1855 to 1884. Among his best-known works are: *La poétique d'Aristote* (1850), probably his most interesting work; *Notions élémentaires de grammaire comparée*, the earliest work of its kind in Europe (1852); *Mémoires d'histoire ancienne et de philologie* (1863); and his masterpiece, *L'Hellénisme en France* (1869), dealing with the influence of the Greek upon the French language. He wrote much on Greek papyri and on Greek inscriptions and was a frequent contributor to the *Mémoires de l'Académie des Inscriptions*, the *Journal de l'Instruction Publique*, *Revue des Deux Mondes*, and to the *Journal des Savants*, of which he became editor in 1871. He was a member of the Academy of Inscriptions and an officer of the Legion of Honor. Consult Bailly, *Notice sur Emile Egger* (Paris, 1886), and Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

EGGER MOTH. A bombycid moth of either the genus *Lasiocampa* or *Eriogaster*. The name is chiefly in use among British lepidopterists and is often spelled *egger*.

EG'GERS, JAKOB, BARON (1704-73). A Swedish soldier and military author, born at Dorpat, Livonia. In 1722 he entered the service of Sweden and devoted himself to the study of the science of fortification. He subsequently served Poland, Hesse (1735), Saxony, and Sweden (1742) where he was quartermaster-general and adjutant to the King and served in the campaign against Russia in 1742-43. He was again in the Saxon army in 1744 and then in the French. He became a Swedish baron in 1772. His description of the siege of

Bergen-op-Zoom, *Journal du siège de Bergop-zoom* (1750), which he witnessed as a volunteer in the French army, is a vivid portrayal of that engagement. In 1751 he published an improved edition of Desbois's *Dictionnaire militaire*, which was followed in 1757 by an independent work, entitled *Neues Kriegs-, Ingenieur-, Artillerie-, See- und Ritter-Lexikon*.

EGGFISH (so called from the shape when inflated). A globefish, especially *Tetrodon*.

EGGLESTON, EDWARD (1837-1902). An American novelist and historian. He was born at Vevay, Ind., Dec. 10, 1837, the son of a lawyer. Of delicate health in childhood and largely self-educated, he began life as a Methodist circuit rider and was then agent in Minnesota for the Bible Society, doing such pastoral work as his health permitted and engaging in other pursuits as opportunity offered. In 1866 he went to Evanston, Ill., and for a time edited a children's paper. In 1867 he removed to Chicago and edited the *Sunday School Teacher*, gaining national reputation as manager of Sunday-school teachers' institutes and as a speaker at Sunday-school conventions. Meanwhile he contributed with increasing frequency to the *New York Independent*, and became its literary editor, and soon afterward superintending editor, a post that he resigned to become editor of *Hearth and Home*, which again he gave up for a Brooklyn pastorate (1874-79), finally retiring to a country place on Lake George and devoting himself to literature. He had already made southern Indiana peculiarly his own in fiction by his racy *Hoosier Schoolmaster* (1871), a great success, appearing first in *Hearth and Home*. He followed it up with other novels, some of them quite popular: *The End of the World* (1872; reissued in an illustrated edition, 1908); *Mystery of Metropolisville* (1873); *The Circuit Rider* (1874); *Roxy* (1878). He now began, with the help of his daughter, Mrs. Lillie E. Seelye, the publication of juvenile biographies of American Indians: *Tecumseh* (1878); *Pocahontas and Powhatan* (1879); *Brant and Red Jacket* (1879); *Montezuma* (1880). In 1883 he returned to Indiana fiction in *The Hoosier School Boy*, continuing with *The Graysons* (1888), *The Faith Doctor* (1891), *Duffels* (1893). His biographical studies led him to a wider study of American history, in which he was mainly interested during his last years. Among his works in this field are *A Household History of the United States* (1888) and a series of volumes on the development of American society, *The Beginners of a Nation* (1891) and *The Transit of Civilization* (1894). His works are marked by a very minute knowledge of Colonial life and thought, and with their attractive style are among the best of recent American histories, in spite of a certain want of sympathy with the mental attitude of the epochs described. In 1900 Eggleston was president of the American Historical Association. Consult O. C. Auringer, *Friendship's Crown of Verse* (Clinton, N. Y., 1907).

EGGLESTON, GEORGE CARY (1839-1911). An American editor, novelist, and miscellaneous writer, brother of Edward Eggleston. He was born at Vevay, Ind., and was educated at Asbury University, Ind., and Richmond College, Va. He studied law, practiced, and served in the Confederate army throughout the Civil War.

In metropolitan journalism he served as managing editor of *Hearth and Home* (1871-74); editor of *American Homes* (1874-75); literary editor of the *New York Evening Post* (1875-81); literary editor of the *Commercial Advertiser* (1884), later its editor in chief (1886-89), and finally a member of the staff of the *World*. He wrote *A Rebel's Recollections* (1874) and also numerous books for the young. More important are such novels as: *Southern Soldier Stories* (1890); *The Last of the Flatboats* (1900); *A Carolina Cavalier* (1901); *Dorothy South* (1902); *A Daughter of the South* (1905); *Life in the 18th Century* (1905); *Our First Century* (1905). Later works are *History of the Confederate War* (2 vols., New York, 1910), and *Recollections of a Varied Life* (New York, 1910).

EGGMÜHL. See ECKMÜHL.

EGGPLANT (*Solanum melongena*). A plant, native of the tropics, usually less than 2 feet high, with stem partially woody; the fruit somewhat resembles an egg in shape, and varies from the size of a hen's egg to 6 or even 8 inches in diameter, in color generally purple, white, or yellow. The fruit is much used as a vegetable in warm countries, especially in the East Indies. It is successfully grown in the northern portion of the United States when started in a hotbed. The white-fruited varieties are said to be most popular in Europe, but in America the black and purple varieties are most in favor. The early dwarf purple is an especially good variety for the Northern States. The New York purple and black Pekin are excellent shipping varieties. The plant grows well in the South on almost any good soil and gives better results with commercial fertilizers than with fresh barnyard manure. Eggplants should be well thinned out in the seed bed and kept growing vigorously. They tend to make rather slow growth the first few weeks and are easily stunted through neglect during this period.

Eggplant Diseases. The diseases to which the eggplant is subject are neither numerous nor very destructive, although at times they become epidemic, scarcely a plant escaping. The anthracnose (q.v.) (*Glaesporium melongena*) attacks the fruits, producing small sunken areas which contain minute pink blotches. A mold (*Botrytis fascicularis*) attacks the fruit, causing a rapid softening in spots, accompanied with a gray mold on the surface. A leaf spot due to the fungus *Phyllactinia hortorum* attacks the leaves, causing the tissues to turn brown, dry up, and fall away, leaving ragged holes. The fruit may also be attacked by this fungus, after which soft, sunken patches appear. The disease spreads until the entire fruit is a rotten mass. All these diseases may be checked in their spread by the use of any of the standard fungicides, e.g., Bordeaux mixture. A bacterial disease caused by *Bacillus solanacearum* is sometimes very destructive. For illustration, see Plate of VEGETABLES, GARDEN.

EGG POWDERS. See EGG as a food.

EGGSHELL CHINA. A very thin and translucent variety of china, originally made in China, but now produced in European factories.

EGG TOOTH. A hard, sharp prominence on the tip of the beak or nose of embryo birds and egg-born reptiles, enabling them to break through the eggshell at hatching time without

injury to the organ. It is described by Newton as composed of calcareous matter, not connected with the underlying bone, deposited in the middle layer of the epidermis of the tip of the upper mandible (of birds). In both birds and reptiles it peels off and is dropped soon after the hatching. An analogous arrangement appears in the great jaws of certain insects, used only for freeing themselves from their cocoons; and Darwin, *Origin of Species* (London, 1882), bases an argument for his theory of natural selection upon the existence of such temporary structures, serving a highly important service only once in an animal's lifetime, pointing out that a small superiority of equipment in this respect might alone save the life of the animal at the critical moment of its attempting to escape from the egg, and that those best endowed would be most likely to survive and perpetuate this useful feature.

EGHAM, ĕg'am. A village in the northwest of Surrey, England, on the right bank of the Thames, 21 miles west-southwest of London (Map: London, F 2). In the vicinity are Runnymede (q.v.) and Cooper's Hill, which was rendered famous by Denham and Pope. Pop., 1901, 11,895; 1911, 12,551.

EGIDY, ä-g'îd. CHRISTOPH MORITZ VON (1847-98). A German soldier and writer on ethical topics. He was born at Mainz, entered a Brandenburg regiment as lieutenant in 1865, and a cavalry regiment of the army of Saxony in 1868. He attained the rank of lieutenant colonel in 1889 and in 1890 retired from the service. His pamphlet, *Ernste Gedanken* (1890), was widely circulated, aroused much discussion and comment, and was the basis of the so-called *Egidy Bewegung* (movement), which in a rather ill-defined way sought to effect a nonsectarian and undogmatic Christianity. *Weiteres zu den Ernsten Gedanken* (1890) and *Ausbau der Ernsten Gedanken* (1891) were supplementary, and in 1892 a quarterly, *Einiges Christentum*, appeared at Kiel (from 1899 at Berlin as a bimonthly with the title *Ernstes Wollen*). Consult Driesmans and Müllberger, *Moritz von Egidy, sein Leben und Werke* (2 vols., Dresden, 1900).

EGILL SKALLAGRIMSSON (c.900-983). An Icelandic skald. His parents were among those who were forced to emigrate after Harold Fairhair's victory at Hafrsfjord. Egill entered the service of the English King Athelstan in 925 and fought under him for several years. He returned to Norway after Harold's death and revenged himself upon his successor, Erik Blóðöx (Blood ax), by killing his son in 934. Afterward he was taken prisoner by Erik and only regained his liberty by composing a number of stanzas praising that King. This poem, which was called *Hofudhlaun* (The Redemption of the Head), was partly translated into Swedish by Sörenssen (1866); and by A. K. Blom, 1899. His greatest saga, *Sonatorrek*, was composed on the death of his favorite son. It is full of the bitterest grief and an unquenchable pride. He also composed a saga to celebrate his friend Arinbjörn, the *Arinbjarnardrápa* (975), translated into Swedish by Björlin in 1864, and the *Skjaldardrápa* (970). The famous Icelandic poem called "Egill's Saga," which some critics suppose to be by Snorri Sturluson, is a glowing description of Egill's career and contains the above-mentioned poems. Consult Jónsson's edition of this saga (Copen-

hagen, 1886-88, and 1894, translated by N. M. Petersen (1862), new ed. by Dahlerup and Jónsson (1901), and Halle, 1894).

EGILSSON, ä-g'îl-sôn, SVEINBJÖRN (1791-1852). An Icelandic philologist, born in Iceland. After completing a course of study at the University of Copenhagen he returned to Iceland. For several years he was rector of the Latin school at Reykjavík. He retired in 1851. Egilsson is best known by his dictionary of Old Norse poetry (*Lexicon Poeticum Antiquæ Linguae Septentrionalis*, 1860). He also published a number of articles on Old Norse and an edition of Snorri's *Edda* (1848-52).

EGINA. See *ÆGINA*.

EGINHARD, ĕg'in-hård. See *EINHARD*.

EGILAMORE, SİR. One of the Knights of the Round Table, and the hero of a popular ballad which tells of his slaying a terrible dragon.

EG'LANTINE (Fr. *églantine*, from OF. *aiglant*, *aiglent*, Portug. *aguien*, sweetbrier, from Lat. *aculeus*, thorn, from *acus*, needle). A name given to two species of rose and sometimes, erroneously, to honeysuckle. The first species, *Rosa rubiginosa*, is a dense shrub, often 6 feet tall, the stems of which bear hooked prickles, dark-green leaves, and, in June, bright-pink, short-stemmed, sweet-scented flowers, followed by orange-red or scarlet fruits. It is a native of Europe, but has become naturalized in many parts of the eastern United States and Canada. Some of its cultivated double forms and some of its hybrids with other species of rose are very attractive. The second species, *Rosa eglanteria*, is a West Asian shrub, with long climbing stems, bearing straight prickles, dark-green leaves, and, in June, yellow flowers, which have to many persons an offensive odor.

EGLANTINE, ä-g'lan-tën', MADAME. The prioress of Chaucer's *Canterbury Tales*.

EGLESTON, THOMAS (1832-1909). An American mineralogist and metallurgist, born in New York City. He graduated from Yale and from the Ecole des Mines in Paris in 1860. In 1861 he was placed in charge of the mineral collections of the Smithsonian Institution. In 1863 he was elected to the trustees of Columbia College, and to a school of mines in New York City, and from the opening of the school in 1864 to 1897 Egleston was professor of mineralogy and metallurgy. This was the first American institution for practical instruction in mining and metallurgy. In 1866 he directed a geological and mineralogical survey of the first 100 miles of the Erie Railroad. He also served as a United States commissioner to examine the Atlantic coast fields of minerals in 1868 and was a member of the International Exposition at Vienna in 1873. The French government honored him with the decoration of the Legion of Honor in 1890. He was one of the founders of the American Institute of Mining Engineers (president in 1886) and also of the American Metrological Society and was vice president of the New York Academy of Sciences (1869-81). His publications include *Tables for the Determination of Minerals* (1867); *Metallurgical Tables on Lead, Iron, and Steel* (1869); *Lectures on Mineralogy* (1871); *The Metallurgy of Gold, Silver, and Mercury in the United States* (1887); *A Catalogue of Minerals and their Synonyms* (1889).

EGLI, ä-g'îl, JOHANN JAKOB (1825-96). A Swiss geographer. He was born at Chwiesen-

Laufen in the Canton of Zurich and after teaching at various schools was in 1883 appointed professor of geography at the University of Zurich. He may be said to have been the founder of the science of geographical nomenclature. His principal works devoted to this subject are: *Nomina Geographica, Versuch einer allgemeinen geographischen Onomatologie* (2d ed., 1893); *Geschichte der geographischen Nomenclatur* (1886). Among his other works are: *Geographie für höhere Volksschulen* (1857; 8th ed., 1887); *Neue Schweizerkunde* (8th ed., 1890); *Neue Erdkunde* (8th ed., 1894); *Neue Handels-geographie* (5th ed., 1892); *Der Name in der geographischen Nomenklatur* (1894).

EGLINTON AND WINTON, ARCHIBALD WILLIAM MONTGOMERIE, EARL OF (1812-61). An English politician. He was born in Palermo, Sicily, was educated at Eton, and succeeded his grandfather as Earl of Eglinton in 1819. He was an enthusiastic sportsman and won the Derby and the St. Leger with Flying Dutchman in 1849. In 1839 he carried out the celebrated tournament at Eglinton Castle, Ayrshire, described by Dryden in *Mac Flecknoe*. He did much for the game of bowls and in 1857 gave a gold bowl and the Eglinton cup as an annual trophy. He was Lord of the Isles of Ireland in 1852 and again in 1853. He was very popular in Scotland and in 1852 was elected lord rector of Glasgow and of Marischal College, Aberdeen. He became Earl of Winton in the peerage of the United Kingdom in 1859. There is a statue of him in Ayr.

EG'LON. 1. A king in Moab, who, according to Judg. iii. 12-30, oppressed Israel for 18 years and was assassinated by the Benjaminite Ehud (q.v.). 2. An Amorite city mentioned in Josh. x. 36; xii. 12, xv. 39. Its King, Debir, is represented as joining the league against Joshua that was led by Joshua (q.v.). The city was evidently a Canaanite city. It has been identified with Khirbet Ajlan, 2 miles north of Tell el Hesry, and with Tell Nejileh, 3 miles south of this place.

EGMOND, COUNT. See EGMONT, LAMORAL.

EGMONT. A tragedy by Goethe, published in 1788. Its plot centres about the revolution in the Netherlands in the middle of the sixteenth century.

EGMONT, JOOST VAN (1601-74). A Dutch portrait and historical painter, born at Leyden. He was a pupil of Cornelius van den Hoecke and afterward studied under Rubens, for whom he painted the "Last Supper" in the cathedral at Malines. Later he went to Paris, worked with Vouet, and was appointed court painter to Louis XIII and Louis XIV. He was one of the first 12 members of the Académie Royale de Peinture, founded in 1648. In 1653 he returned to Antwerp, his son Constantine, with whom he is sometimes confounded, remaining in Paris. He designed many cartoons of historical subjects for tapestries and painted a large picture of the genealogy of the counts of Egmont, but is best known for his portraits in the style of Van Dyck. They include Philip IV of Spain and the Archduke Leopold Wilhelm (Vienna); Maria Aldegonde, Jan Cornelis, and Alexander Gouhon as children (Antwerp Museum).

EGMONT, or EGMOND, LAMORAL, COUNT, PRINCE OF CAVRE (1522-68). A Flemish general and statesman, born at the castle of La Hamaide in Hainault. He succeeded his elder brother

Charles in the title and estates in 1541, accompanied Charles V on the Algerian expedition in the same year, and followed that monarch afterward in all his campaigns against Francis I. His bravery and devotion were rewarded in 1546 with the order of the Golden Fleece. The year previously he had married Sabina of Bavaria, the sister of the Elector Palatine, with great pomp in the presence of the Emperor at Speyer. In 1554 Egmont was sent to England to negotiate the marriage between Mary and Philip. After the accession of Philip II he commanded the cavalry in the battles of St. Quentin and Gravelines (qq.v.); and when Philip finally returned to Spain, he left Egmont as Stadtholder of Flanders and Artois. When Margaret of Parma, against the will of the Protestant party, was made Regent General of the Netherlands, Egmont and the Prince of Orange entered the Council of State and opposed the ultra-Catholic policy of Cardinal Granvella and the Regent. On Egmont's threatening to resign Granvella was withdrawn from the Low Countries, and in 1565 the Count visited Philip at Madrid and departed homeward full of confidence in the King. But the reactionary edicts of Granvella were ordered to be enforced with more severity than ever, and the people were roused to rebel. When the insurrection broke out, Egmont opposed the Radical party, banded in the "Beggars' League," as it was called. He seems to have remained neutral even when, in April, 1567, his bitter enemy and rival, the Duke of Alva, was sent as lieutenant general to the Netherlands. (See ALVA.) The Prince of Orange and other chiefs of the insurrection left the country, while Egmont, wishing to save his private property, remained, thinking his loyalty and services had secured his safety. He appeared to have gained Alva's confidence, when suddenly, after a sitting of the Council, he and Count Horn were seized and carried to the citadel of Ghent. The Estates of Brabant sought to withdraw them from the Bloody Tribunal, as it was called, instituted by Alva, and Egmont, as a knight of the Golden Fleece, denied its competency. His Countess pleaded earnestly in his behalf, and intercession from the highest quarters was made to Philip. At his trial he was accused of having favored the enemies of the Catholic religion and of plotting the overthrow of the King. Ninety charges were brought against him, which he did not trouble himself to answer in detail, but protested his innocence, and showed clearly that he had been a loyal subject and faithful counselor of the King. Nevertheless, he was condemned to death by Alva and his tools, and on June 5, 1568, was executed in the great square of Brussels at the same time as Count Horn. Their death made them martyrs to the cause of liberty in the Netherlands, and in 1865 a monument by Fraiken was erected to their memory at Brussels. Goethe has made Egmont the hero of one of his finest tragedies. One of the best brief accounts of Egmont is given by Schiller in his *Abfall der Niederlande*. Consult Motley, *Rise of the Dutch Republic* (London, 1861); Blok, *History of the People of the Netherlands*, vol. iii (New York, 1900); Juste, *Le comte d'Egmont et le comte de Hornes* (Brussels, 1862); De Bayay, *Procès du comte d'Egmont et pièces justificatives* (ib., 1853); also the published correspondence of Philip II and of Margaret of Parma.

EGNATIA. See FASANO.

EGNATIS. See GNATIS.

E'GO (Lat., I). A term much used by philosophers to denote the conscious self or person, especially when idealistically conceived as the metaphysical subject whose activity is supposed to give rise to the world of experience.

E'GOISM. A term formerly sometimes applied in philosophy to any view that was supposed to make the individual self the only reality knowable. It is now used almost entirely in an ethical sense as an antonym to altruism (q.v.). It denotes either the practical attitude which makes one's own private welfare the sole end of one's endeavor, or the theoretical view that such an end is the only one reasonable or possible. See ETHICS.

E'GRET (Fr. *aigrette*, diminutive of dialectic *égren*, OF. *hiron*, Fr. *héron*, heron). A name often given to various species of heron (q.v.), particularly those of white plumage which, at least during the breeding season, have the feathers on the lower part of the back lengthened and their barbs loose, so that this part of the plumage is very soft and flowing. These plumes are used for ornamental purposes. (See AIGRETTE.) In old English bills of fare the "egrittes" which are mentioned are not herons, but lapwings. Two species of egret are known in Europe—a large one (*Ardea alba*) and a small one (*Ardea garzetta*). In the southern United States three species of heron are known as well as the American egret (*Herodias egretta*), the snowy egret (*Egretta candidissima*), and the reddish egret (*Dichromanassa rufescens*). All three were formerly abundant to a remarkable degree in Florida, but are now rare, owing to persistent destruction of them in the breeding season for the sake of their plumes. Few chapters in American ornithology are so sad as the story of the slaughter of Florida's herons to supply the demands of an inexcusable and barbarous fashion. The setting aside by both the government and by private individuals of islands and large tracts of marshlands has probably insured the extermination of these beautiful birds. The reddish egret is of special interest because it illustrates the curious phenomenon known as *dichromatism*, some of the birds being pure white, while others are dark bluish-slate color, and this difference does not seem to be connected with age, sex, or season. Consult Hornaday, *Our Vanishing Wild Life* (New York, 1913). See DICHRMATISM; HERON; and Colored Plate of WADERS.

EGUISHEIM, ä'gis-him. An archæological station near Colmar, Alsace, at which fragments of a human skull of Neanderthal type were found. Consult, *Le préhistorique* (Paris, 1900).

EGUSQUIZA, ä'güs-ké-ä, JUAN BAUTISTA (1845-). A South American politician and a president of Paraguay, born in Asunción. In the war against Brazil, Argentina, and Cruguary, he rose to be a lieutenant colonel. Subsequently he became Secretary of War and general. In 1894, following upon the summary deportation to Buenos Aires of President Gonzalez, he was elected President of the Republic for the term ending in 1898. His administration was in the main peaceful and progressive, although he so managed the dispute with Bolivia over the boundary line that war was averted chiefly by the success of the revolution that forced him out of office.

EGYPT. A country occupying the northeast corner of Africa. Egypt proper extends from

the Mediterranean south to lat. 22° N. (For an account of the agreement between the British and Egyptian governments, Jan. 19, 1899, see SUDAN, ANGLO-EGYPTIAN.) The boundary on the east is the Red Sea and on the extreme north-east Syria. This northeastern line falls within the Sinai Peninsula and was finally approved on Oct. 1, 1906, by a Turco-British convention. The west boundary separates Tripolitania from Egypt and is not yet (July, 1914) delimited, but negotiations between England and Italy are in progress for its final settlement. The oasis regions in the eastern third of the Libyan Desert belong to Egypt. The northernmost point of the country is in lat. 31° 40' N. Egypt thus extends 675 miles north and south, with a general breadth of about 500 miles. Its area is about 400,000 square miles, but the cultivated region in the Nile valley and Delta includes only about 10,000 square miles, about 9,000,000 people being crowded into a space about as large as the area of New Hampshire. About 92 per cent of the entire population consist of Mohammedans. The remaining 8 per cent consist of Christians and about 40,000 Jews. Of the Christian churches the Coptic Orthodox has by far the largest number of adherents,—about 665,000.

Topography. Egypt is a part of the great desert zone of North Africa. Four natural features distinguish parts of the country from the expanses of sand that stretch away in all directions. West of the Nile, in the barren wastes of the Libyan Desert, many little regions of depression occur where the surface is below sea level, or only a few hundred feet above it. Oases constitute the only centres of settlement in these regions. Their water is derived by infiltration from the Nile or from other sources of subterranean supply. Jof, in the Kufra group, was the home of the Senussi Mahdi, whose followers, in various parts of Africa and Asia, number some millions of Mohammedans. (See MOHAMMEDANISM; SENUSSI.) The second distinctive feature lies to the east of the Nile—a district of mountains. The Nubian Desert, a long piece of country between the Nile and the Red Sea, with Cairo and Suez as its northern, and Assuan and Berber as its southern corners, is a triangular district, 150 miles broad, rising gradually from the Nile over sandy wastes and hills of secondary formation for 100 miles, where the elevation is about 2000 feet. Down the centre runs a main ridge or backbone of granite or primary rocks, from which the desert slopes more steeply and evenly to the sea. Clouds hang around the tops of these mountains in winter, and there is sufficient precipitation to provide water and herbage for the scanty flocks of the Bedouins. Along the Red Sea is a line of jagged mountains whose highest summit is about 7000 feet. The third distinctive feature lies south of Assuan—a region of desert hills and of pitiless sand plains, the northern part of the Nubian Desert. This district is bordered on the west by the Nile with its thin fringe of vegetation. The fourth distinctive feature is the valley of the Nile.

The First Cataract, the only one in Egypt, is just south of Assuan. The course of the Nile from the southern boundary of Egypt to the sea is about 800 miles. The Lower Nile, from Assuan to Cairo at the head of the Delta, is much visited by tourists. This riverain region, fertilized by flood waters and irrigation canals for

an average breadth of 9 miles, yet the Delta, from Cairo to the sea, is covered with a network of navigable streams and irrigation canals, is the garden of Egypt. Most of the population and agricultural interests are grouped here, with Cairo, the political and administrative centre, on one side, and Alexandria, the chief port and commercial centre, on the other. On the west side of the Nile, southwest of Cairo, is the depressed valley of Fayum, a fertile tract, in the northern part of which is the lake called Birket-el-Kerun.

Climate. In the southern part of Egypt there is considerable rainfall; over a large part of Lower Egypt there is practically no rain. On the immediate shores of the Mediterranean, however, there is some precipitation, owing to proximity to the sea. Thus, at Alexandria, on the coast, the rainfall is on the average $8\frac{1}{2}$ inches, while at Cairo, at the head of the Delta, it is but 1 inch. There are great differences in temperature. Near the sea, where its influences are felt, the temperature rarely reaches the freezing point, while sometimes during the prevalence of the land wind from the south, the Khamsin, it has been known to reach 114° F. In Lower Egypt, where desert conditions prevail, great contrasts of temperature are observed. Throughout this region the air is extremely dry, and the sky is clear, the average annual cloudiness being not over 20 per cent. The winds blow from the north and northwest during the fall and winter, but in the spring and summer are often from the south. The hot south Khamsin blows chiefly during April and May. There are two seasons—a hot season from May to September and a cool one from November to March. October and April are transition periods. In the Nile valley distinction is made between the period of inundation from July to October; the planting season from November to March, and the summer from March to July.

Flora. The date palm and figs are the chief trees of Egypt, but all kinds of fruits which flourish in a dry climate are found. Among these are lemons, oranges, and figs. Tamarisks and thorny acacias occur in the less dry deserts. Egypt is renowned in the Levant for its vegetables, the country's damp soil favoring their growth admirably. Many species of trees have been introduced, and where they can obtain sufficient moisture they thrive well. There are no forests. Clover, grains, and cotton, the latter constituting the country's most important agricultural product, are extensively grown in the watered region, and in the Delta region rice and sugar cane. Tobacco might be a large crop, but its cultivation has been prohibited since 1890. Durra, the almost extinct papyrus, and the lotus are characteristic Egyptian plants. Many of the khedives have encouraged tree planting. A splendid shade tree known as the lebbek (*Albizia lebbek*) has been introduced in the valley of the Nile. It attains a height of 80 feet in half the number of years.

Fauna. Considered with respect to its animals, Egypt is essentially a part of Europe and not at all Ethiopian. It is, in fact, like the whole south shore of the Mediterranean, classed as a part of the Palearctic Province. (See DISTRIBUTION OF ANIMALS.) Perhaps no equally extensive part of the world has witnessed so great a change in its fauna as has occurred in the lower valley of the Nile during the 6000

years that it has been the seat of historical human occupation. Originally, no doubt, a large area, if not the whole breadth of the country on both sides of the Nile, was clothed with forests, which sustained a great variety of animals that disappeared with the destruction of the trees; and, on the other hand, some of the most characteristic of the animals of modern Egypt have become so only through man's occupation. Anciently many of the animals of the tropical Nile followed the river down to its Delta, including the elephant and hippopotamus. Crocodiles abounded within historic times, but have long been absent below the cataracts of the Nile. The river still furnishes a great variety of fish, few of which, however, are desirable for the table. Among them is the strange ganoid bichir (q.v.). Many varieties of waterfowl and wading birds, mainly the same as, or closely related to, European forms, move with the seasons up and down the river. Birds of prey are especially frequent in Egypt, where kites abound in the towns and do an important service towards keeping them clean. In winter hosts of familiar European birds are present. Several species of antelope, now becoming rare, such as the addax and oryx, approach the Nile from the Sahara. The wild ass is still to be seen in the remoter southern parts. Egyptian horses have an ungainly appearance, but are exceedingly hardy. Snakes are common, among them the deadly asp. The desert supports jackals and foxes (fennecs), and packs of striped hyenas haunt the caravan trails and neighborhood of rural villages. Lions are no longer to be seen except on the borders of the Sudan or in the rough mountains along the Red Sea near Abyssinia. Leopards are somewhat more numerous. Among the domesticated animals is the ichneumon. Camels are found in the large desert areas. Their flesh is highly relished in the flatlands. Oxen are used for plowing throughout Upper Egypt. Goats and fowls are very abundant.

Geology and Mineral Resources. Egypt has no geological features distinct from those common to the rest of Africa. The fundamental igneous and metamorphic rocks which underlie the horizontal strata of the Sahara and the Sudan extend across the Nile into the Arabian Desert and are prominent in the range of mountains lying along the western shore of the Red Sea. These rocks in many places support a sedimentary cap called the Nubian Sandstone, a formation that also appears in various localities on both banks of the Nile. In Lower Egypt Cretaceous and Tertiary limestones are extensively developed. The quarries of Egypt in ancient times produced great quantities of granite, porphyry, sandstone, and limestone, suitable both for building and for sculptural purposes; but they are now worked only intermittently. In other respects the mineral resources of the country are limited. The salt marshes of the Delta produce salt, soda, and alum, and some saltpetre is manufactured. The gold mines, which, according to ancient records, were worked as early as 2500 B.C., have been rediscovered in the crystalline rocks of the rugged mountains east of the Nile where abundant evidences of the old workings are found. Most of the auriferous quartz veins are found in the lower ranges. Petroleum has been discovered about 190 miles south of Suez close to the Red Sea coast. Copper mines, which are known to have been worked

by the Egyptian kings of the early dynasties, are known in the Sinai Peninsula.

Agriculture. Egypt is essentially an agricultural country, two-thirds of the inhabitants with declared occupations being engaged in farming. It differs widely in this respect from most other countries by reason of its dependence on the annual overflow of the Nile or artificial irrigation. (For a description of this river and its irrigation see NILE.) Since the British occupation in 1882 irrigation has been made towards the full use of the annual overflow, by the construction or improvement of huge dams, particularly the Barrage at the head of the Delta, which raises the level of the river and permits the perennial irrigation of a large part of the Delta lands. The soil, when irrigated, is of extraordinary fertility, owing to the amount of organic matter contained in the waters of the Nile. Three crops a year may be raised wherever perennial irrigation is supplied. The crops in the winter season (October to March), when the Nile carries water in excess of actual needs of agriculture, are wheat, beans, barley, vegetables, and clover. The crops of summer (April to July) are cotton, sugar cane, millet, rice, vegetables, and fruit. This is part of the season when the river is at its lowest. There can be little summer tillage excepting where perennial irrigation is supplied. The crops of the flood season are maize and millet. The total cultivable area in Egypt is about 3,000,000 acres, of which about three-fourths is cultivated, the remainder requiring irrigation or, in certain instances, drainage.

In the district of the Delta most of the cultivated area is under perennial irrigation, and where this exists three crops a year may be grown. The richest crops are raised in the Delta and in the Sefi (summer water) Canal areas of Upper Egypt.

Formerly a large share of Upper Egypt received its water supply by a division of the land into huge basins, formed by the construction of cross embankments extending from the river to the foothills. These basins were filled with the mud-charged waters during high Nile, and after the mud had settled the clear water was allowed to flow off, and the land, with its coating of new soil, cultivated. It often happened, however, that the supply of water for irrigation ran short in the season of low Nile, and barrages, or weirs, were constructed to deflect the waters from the natural course of the river to the basin areas under cultivation, this system having been successfully utilized in the Lower Nile by the barrage at the head of the Delta, about 12 miles above Cairo. It was subsequently found, however, that the water supply in the season of low Nile was insufficient to meet fully the requirements of the area occupied by the basins, and a great barrage was constructed at the First Cataract (see NILE), near Assuan, about 550 miles by rail south of Cairo. This great work, known as the Assuan Dam, was completed in 1902 at a cost of \$10,000,000 and created a lake or reservoir about 200 miles long in the valley of the Nile above the First Cataract, the storage of the waters being begun only after the early portion of the flood with its supplies of new soil had passed to the basin lands. (See DAMS AND RESERVOIRS.) The storage capacity was estimated at 3,750,000 million cubic feet. Even this supply, for use during the later months for perennial irrigation purposes, proved in-

sufficient, and the dam was raised 27 feet, this work being completed in December, 1912, and increasing the estimated storage capacity of the great reservoir to about 9,000,000 million cubic feet. It is expected that this retention of the surplus water, for use when required and thus giving perennial irrigation to a large share of the Upper Nile region, will increase its production fully 50 per cent. The system did not fully meet expectations in 1913, owing to the fact that the Nile floods were unusually late and the supply of water less than usual. There has also been difficulty in educating the native population as to the amount of water which may advantageously be used. Drainage works, being introduced in Lower Egypt to make available certain areas occupied by shallow lakes, will further increase production. In the broadest sense the staple crops are cotton in the Delta and cereals both in the Delta and in Upper Egypt. Egyptian cotton has been recognized since 1821 as supplying a long fibre unsurpassed in quality except by American Sea Island. The crop, about one-tenth as large as that of the United States, is in demand in all manufacturing countries for the finer qualities of goods in which strength and lustre of fibre are required. Cotton culture is rapidly extending in Upper Egypt, but three-fourths of the crop is still in the Delta. The cotton crop has suffered in late years from insect pests, due in part to the destruction of bird life, also from the lack of proper selection of seed. The production amounts to about 750,000,000 pounds per annum, valued at approximately \$150,000,000. Raw silk is produced to a small extent. The rice crop is confined to small districts in the Delta and in the salt lands in the Delta along the Mediterranean shall have been reclaimed, it is expected that Egypt will grow all the rice needed. At present large quantities are imported. Wheat and maize are very large food crops, the surplus being sent to Europe. The wheat area is about equally distributed between the Delta and the rest of Egypt, but maize culture predominates in the Delta.

In regard to the form of tenure the land is divided into three classes: (1) the Kharaji, or land owned by the state, comprising about three-fourths of the land under cultivation, mostly rented in small parcels to the natives; (2) the Ushuri, or land originally granted in fee to large landholders, comprising less than one-fourth of the cultivated land, subject to a tax equal to about one-third of the rent paid by the fellahs, or tenantry; (3) the Waki lands, or lands belonging to the mosques and charitable institutions, and rented by them, usually for long terms. In the first half of the nineteenth century, when the treasury was impoverished by the immense expenditures on military works, the fellahs, besides being compelled to do forced labor on public works, were also forced to pay a burdensome rent in kind and to sell their crops to the government at prices arbitrarily fixed by the Pasha. At present the rent is paid in money, and the farmer is in no way interfered with in the disposal of his crop. The large indebtedness of the agricultural population seriously affects the agricultural conditions of the country. Although the legal rate of interest is only 9 per cent, the rate exacted by the money lenders is much higher. Measures have been taken towards the elimination of usury by allowing the National Bank to advance small sums to

the farmers at 10 per cent, and, judging from official reports, this policy seems to have been sufficiently successful to warrant its extension. The distribution of land in 1911 was as follows: Of the 1,441,250 holdings, 1,296,561 contained 5 feddans and under (a feddan equals 1.038 acres); 76,382 contained between 5 and 10 feddans; 36,461, between 10 and 20 feddans; 11,188, between 20 and 30 feddans; 8265, between 30 and 50 feddans; and 12,393, over 50 feddans. The area devoted to wheat in 1912 was 1,447,000 acres, and the yield 4,205,000 tons; barley, 382,327 acres, 1,234,000 tons; maize and millet, 1,925,000 acres, 9,353,000 tons; the sugar exports amounted to £ E. 182,306, raw cotton £ E. 27,529,000, and cotton tissues £ E. 3,500,000 (Egyptian pound, \$4.943). There are over 5,000,000 date trees, which, besides supplying the home demand, yield some fruit for export. The domestic live stock of the country is increasing in number and includes nearly 1,000,000 sheep and goats (some wool is exported), 500,000 cattle and buffaloes, and 50,000 camels; while horses, mules, and donkeys are found in every city and village. Hogs are raised by the Copts of Upper Egypt and bought by Greek and German butchers to sell to European residents.

An important event in 1913 was the enactment of the "Five Feddan" law, which laid down that distraint could not be levied against the agricultural property of cultivators consisting of 5 feddans or less, the purpose being to protect this class against exorbitant demands of small foreign usurers scattered throughout the country.

Manufactures. Egypt has few manufacturing establishments, and the weaving of linen and fez, which dates from an early time, is in a state of decline. There are a number of sugar refineries worked by foreign capital, Egypt having become a sugar-exporting rather than an importing country. A few cotton mills are also operated. The making of Egyptian cigarettes is a large export industry. Tobacco growing is prohibited, both to prevent the use of inferior home-grown leaf in the cigarette factories and also to increase the import revenues. Export cigarettes are made chiefly of Turkish tobacco. The value of cigarettes exported in 1912 was approximately \$2,000,000. During the reign of Mehemet Ali a number of state industrial establishments were founded, but most of them have been closed.

Transportation and Communication. Almost the entire foreign trade of Egypt passes through Alexandria, the shipping of that port in 1911 amounting to 6,800,000 tons, including both entrances and clearances, about 43 per cent of which is carried in British bottoms. The railway lines of Egypt, with the exception of eight agricultural roads built for service on farms, are owned by the government. At the beginning of 1911 there were 1481 miles of railway owned and operated by the state, and 763 miles of agricultural roads in private hands. Traffic on the state lines shows a decided increase. In 1911 the number of passengers carried on the state railways was 27,941,000; the tons of freight were 4,313,501; the net receipts were £994,000 (Egyptian). In 1904 the respective figures were 17,724,924; 3,529,600 tons, and £1,233,300 (Egyptian). The agricultural roads have increased rapidly in number during recent years, with great benefit to agricultural communities. A department of roads was established in 1913 with the object of developing

highways over which motors could be used for commercial and general transportation in the absence of animal power. See SUEZ CANAL.

Commerce. Egypt has acquired considerable importance in the world's commerce on account of its geographical situation. The advantages conferred by its position render its northeastern section the most important point on one of the world's longest sea routes in addition to its being the connecting stage of the land route between Asia and Africa. Cairo (q.v.) is the meeting place of all caravans, whether religious or commercial, that ply between the two continents. Ivory, ostrich feathers, and hides are thus brought to Egyptian bazars from the interior of Africa. Alexandria is the natural seaport for communication with Europe.

The economic development of Egypt under the British rule, brought about by the improvement in transportation and irrigation facilities and the readjustment of the finances, is probably best shown by the increase in its foreign commerce. During the period 1896-1912 the exports of merchandise increased from £ E. 13,232,108 to £ E. 34,574,321, while the imports increased during the same period from £ E. 9,828,604 to £ E. 25,907,759. Naturally Great Britain occupies the foremost position among countries trading with Egypt. The imports from Great Britain rose from £ E. 3,056,000 in 1896 to £ E. 7,990,658 in 1912. In the exports Great Britain's share is even larger, the exports to Great Britain having increased during 1896-1912 from £ E. 5,073,000 to £ E. 16,022,318. The imports from the United States amounted in 1912 to £ E. 403,525, and the exports to £ E. 4,120,895. The chief exports are cotton, £ E. 27,520,271 in 1912, cereals and vegetables, £ E. 2,730,469, and cigarettes, £ E. 422,866. The chief imports were in 1912: textiles, £ E. 6,907,673; cereals and vegetables, £ E. 3,066,000; metals and manufactures, £ E. 2,921,896; wood, coal, etc., £ E. 3,062,000. The magnitude of the cotton exports usually turns the so-called balance of trade in favor of Egypt. The cotton goes mostly to Great Britain, from which are imported chiefly cotton goods, wood and coal, metals, and metal products. The quantity of Egyptian cotton imported into the United States in 1913 was approximately 100,000,000 pounds, valued at about \$20,000,000. Marseilles buys most of the cottonseed. The commercial relations of Egypt are important also with Turkey, France, Algeria, and Austria-Hungary. As the industrial development is small, the imports of textiles (over one-fourth of all foreign purchases) and other manufactures are very large. As Egypt has no forests, timber and lumber from northern Europe and Austria-Hungary are important. The United States buys Egyptian cotton to the value of 10 times that of the goods it sells direct to Egypt, though some products of the United States reach Egypt by way of England and Germany. The foreign commerce is principally in the hands of Europeans, the natives confining themselves to the internal trade.

Government. Egypt is a tributary state of Turkey, but the office of Governor-General or Khedive is vested permanently in the descendants of Mehemet Ali, who was appointed Governor of Egypt in 1805 and succeeded in making himself independent ruler of the country. In consideration of an annual tribute of £750,000 Turkish (a Turkish pound is \$4.40), the Khedive formerly enjoyed absolute rule in Egypt in spite of the presence in his council of a high

commissioner from Constantinople. Absolute legislative and administrative power was formerly vested in the Khedive and a council of six native ministers under his control. In 1913, however, a new system was introduced, upon the recommendation of Lord Kitchener, the British agent and Consul General, with a Legislative Assembly of 89 members, of which three-fourths are elected by district electors chosen by popular vote in proportion to population; the 23 appointive members to include four Copts, three Bedouins, two merchants, one professor and one pedagogue, and one municipal representative. This body is to have actual legislative functions, those of the former Assembly having been nominal and merely advisory in character. The new Legislative Assembly was opened in January, 1914, in the presence of the Khedive, Lord Kitchener, and with messages of congratulation from the British King and others high in authority. The ministers preside over the departments of the Interior, Finance, Justice, Public Works and Instruction, War and Marine, and Foreign Affairs. The most important offices in the ministerial departments, and especially in the departments of Public Works and Finance, are filled by Europeans. Between 1879 and 1883 England and France jointly exercised a guiding influence on the administration of the country through their controllers general, the two nations having intervened in Egyptian affairs for the protection of their respective bondholders, whose interests were threatened by the state of disorder prevalent in Egypt. The rebellion of Arabi Pasha was followed by the abolition of the joint control of the two nations, and by the appointment of an English financial adviser, whose consent was necessary to all fiscal action. Since that time the financial adviser has steadily increased his powers, until now, through the importance of his office, he is practically the ruler of the country.

The influence of England is also made predominant by the control of the public defenses. The Egyptian army has been drilled by English officers and is in a great measure commanded by them, the head of the national forces being an English general bearing the title of sirdar. Besides the regular Egyptian army there has been in the country since 1882 a British army of occupation, towards the support of which the government of the Khedive contributes in part. The British garrison or army of occupation includes four battalions of troops in the Delta and one battalion in the Sudan. There is one regiment of cavalry, a horse artillery battery, a mountain battery, and a company of engineers. The Egyptian government contributes £E. 150,000 towards the cost of these troops. Egypt proper is divided into 5 governorships and 14 mudirihs or provinces, which in turn are subdivided into districts and communes. At the head of the province is the mudir, who is assisted in the performance of his various functions by a sanitary board, a police bureau, and a chief engineer. He also exercises authority over the heads of districts and communities, which in turn exercise control over the representatives of the villages and municipal wards. The collection of taxes is carried on through the mudir.

Finances. The administration of the finances of Egypt may be said to be entirely in British hands, for while the Caisse de la Dette, which has charge of the payment of the foreign debt of Egypt, contains representatives of all the great

European powers, the British financial adviser has control of the country's finances. In evidence of the improvement in financial conditions, it may be stated that the receipts have exceeded the expenditures since 1888, leaving a considerable surplus which is now used for public works, such as irrigation, railways, etc. The chief sources of revenue are land taxes, about 45 per cent of the total, and taxes on tobacco and salt, public works and customs. The chief items of expenditure are the service of the debt (about £3,500,000 Egyptian), the costs of administration, and the operation of public works. The foreign debt exceeds the expenditure, and the abolition of the provincial octroi in 1901 and an increase in railway expenditures. In 1912 the revenue was estimated at £E. 15,900,000 and the expenditure £E. 15,400,000. The foreign indebtedness of Egypt dates from 1862, when a loan of £3,292,800 was issued for the purpose of extinguishing the floating debt. By 1870 the debt had been increased to £38,307,000 and was subsequently increased by a new loan of £32,000,000 issued in 1873. In 1876 the several issues were consolidated into one debt of £91,000,000. Owing to subsequent financial difficulties, the debt was again divided into a floating debt of £17,000,000 at 5 per cent and a fixed debt of £59,000,000 at 7 per cent while the Daira loans were consolidated into the Daira Sanieh debt of £8,815,430 at 5 per cent. The Daira Sanieh debt was paid in October, 1905. Since the passing of the financial control into the hands of European powers many changes have been made in rates of interest, and a number of new loans have been issued. In 1912 the foreign debt consisted of the 3 per cent guaranteed loan of £7,318,500 (English); the privileged debt of £31,277,790 at 3½ per cent; the unified debt of £55,471,000 at 4 per cent; and the domains loan of £203,420 at 4½ per cent. Reserve funds, established in 1887, amounted in 1911 to £5,847,612 (Egyptian). On Jan. 1, 1913, the debt stood at £E. 94,349,680.

Justice. Justice is administered by four classes of tribunals. There are (1) the native courts, which deal with civil actions between natives and with crimes committed by natives; (2) the consular courts, which exercise jurisdiction in the case of foreigners accused of crime; (3) the mixed tribunals, which date from 1875 and try all civil actions between persons of different nationalities and, in a measure, criminal actions against foreigners. The mixed tribunals, which were created by international action, are renewed every five years. Finally, there are (4) the Mohammedan courts, conducted according to the precepts of the Koran and the general code of the Mohammedan religion. These courts deal chiefly with the questions of personal rights of the Mohammedan inhabitants. The system of native courts comprises seven courts of the first instance for the trial of important cases, 47 summary tribunals for the hearing of cases of minor importance, and a court of appeal at Cairo, about one-half of its members being Europeans. The native judges are drawn from the class of the Ulemas, or those learned in the Mohammedan law. Some attempt towards the systematization of the native jurisprudence has been made in the publication of a code of laws, which was in the main a blending of religious precepts with secular law. The administration of justice in the lower courts is

under the supervision of a judicial committee, to which the judges or kadis are responsible for their action.

Population. The population of Egypt in 1846, 1882, and 1907 was respectively 4,476,440, 6,813,919, and 11,287,359, the average annual increase being 1.25 per cent for the period 1846-82 and 2.76 per cent for 1882-97. Of the total population in 1907, 10,366,046 (including 97,381 nomads) were Egyptians (Copts and Bedouins, who constitute the great bulk of the population, Arab inhabitants of the towns, and Bedouins and Copts), 62,973 Greeks and Tunisians, 34,926 Italians, 20,653 British and Maltese, 14,941 French, 69,725 Turks, and 65,162 Sudanese. There also are a large number of other nationalities. The population in the villages and smaller towns is purely Egyptian, while in the larger towns Arabs and foreigners predominate. The census of 1907 gave the population of the principal cities and towns as follows: Cairo, 654,476; Alexandria, 332,246; Port Said, 49,384; Assiut, 39,442.

Religion. About 10,366,826 inhabitants, or 92.23 per cent, profess the Sunnite Mohammedan faith; 706,000 are Copts (q.v.), 77,000 Greek Orthodox, 123,000 Eastern Christians, 58,000 Roman Catholics, 28,000 Protestants, and 38,635 Jews, these figures being those of the census of 1907. The Armenians have a bishop in Cairo. The Maronites are also represented. The Roman Catholics have two churches in Alexandria and two in Cairo. Missionary undertakings in Egypt have not been particularly successful. The Copts are bigoted and exclusive and not well disposed towards other Christian bodies. There is an American mission at Alexandria and Cairo, which works chiefly among the Copts and Jews. A training school was established at Assiut in 1865. Various Roman Catholic missions, such as the Christian Brothers, the Sisters of the Holy Spirit, and Poor Clares, are doing much in the way of charitable and benevolent work.

Education. Education among the natives is in a very low state. In 1907 about 8.5 per cent of the males and about 3 per cent of the females of the native Egyptian population were able to read and write, while the proportion among the Coptic male inhabitants was approximately 50 per cent, and among foreign inhabitants 74 per cent. Elementary education among the Mohammedans is mainly in the hands of private teachers or is provided for by schools attached to the mosques. At the head of the Mohammedan educational system is the great theological seminary at the mosque of El-Azhar, the oldest and greatest university in the Moslem world. (See CAIRO.) The subjects on which instruction is given here are the old traditional branches of the Mohammedan creed; and the system of pedagogy is as antiquated as the studies which are pursued. Schools attached to mosques, and known as Kuttabs, exist in all cities and towns. The government extends certain supervision over these. The instruction is elementary, a part being memorization of parts of the Koran. An attempt to institute a system of public schools, made by Mehemet Ali, succeeded only in part. In 1907 there were about 12,000 elementary schools in the country, with approximately 17,000 teachers and about 250,000 pupils, and 20,000 attended the mission schools supported by the various creeds—Roman Catholic, Greek Orthodox, the United Presby-

terians of America, and others. In furtherance of a policy of cooperation between the Ministry of Education and the provincial councils the latter are assuming charge of all elementary and primary schools and the former all secondary institutions. In 1912 there were under direct control of the Ministry of Education 208 establishments, with about 25,000 pupils, of whom one-fifth were girls. Those under inspection by the ministry numbered nearly 4000, with an attendance of 228,000, of whom about 10 per cent were girls. The vast mass of students of all grades, therefore, still receive instruction at the hands of Mohammedan religious instructors.

Army. The present Egyptian army was organized in December, 1882, by a British general officer under the title of sirdar. The army consists of a little over 18,000 men, with whom there were serving in 1910 about 140 English officers. About 6000 British troops are permanently garrisoned in Egypt, to meet the cost of which the Egyptian government is required to pay \$741,000 annually.

ANCIENT EGYPT

The Land. To the ancients Egypt was that portion of the Nile valley extending from the First Cataract (lat. 24°), near Syene, on the south, to the Mediterranean on the north. On either side the land is shut in by rocky ridges, which extend on the east to the Arabian, on the west to the Libyan Desert. Somewhat to the north of lat. 30° these ridges open out to the northeast and northwest respectively, bounding a district which, from the resemblance of its outline to the fourth character in the Greek alphabet, was called the Delta. Through the Delta the Nile flowed into the sea by separate mouths. Ancient writers enumerated seven such mouths, but the course of the river has shifted repeatedly into new channels, and at present there are but two mouths, situated at Damietta and at Rosetta. The Egyptians called their land *Qemet*, 'the black land,' from the contrast between the dark alluvial soil and the red sand of the adjacent deserts. The origin of the Greek name *Αἴγυπτος* (whence Latin *Egyptus* and our *Egypt*) is obscure. The land was divided into Upper Egypt, called 'the south,' *Qema*, or 'the south country,' *Ta-res* (later *Pa-ta-res*, whence the biblical *Pathros*), and Lower Egypt, including the Delta (*Ta-meh*). In the earliest historical period Upper Egypt contained many marshy tracts, later filled up by alluvial deposits, and the Delta, the name of which was given to this portion of Egypt by the Greeks, which even now has a thin soil, was one vast marsh, though it afforded good pasturage for cattle and was a favorite resort for hunting wild fowl. In the course of time the constant deposits of alluvial matter considerably increased the area of arable land both in the north and in the south, but from the first the conditions were more favorable for agriculture in Upper than in Lower Egypt, and in the time of the Old Empire the Delta was far behind the southern part of the country in civilization. Upper Egypt was early divided into some 20 provinces, or counties, called *nomes* (*νομοί*) by the Greeks, which probably represent tribal divisions, and later, in obvious imitation of this division, a similar number of *nomes* is found in Lower Egypt as well. At times the number of the *nomes* varied, but in general it was from 40

to 42. The capitals of the nomes were each the seat of a particular divinity or group of divinities. How the boundaries of these nomes were determined is unknown.

Ethnology. The ancient Egyptians believed themselves to be an indigenous people, free from "mixture, and all the known facts of their contention. Both their language and their physical characteristics show that they belonged to the Hamitic branch of the Caucasian race, the white inhabitants of northern Africa. They represent this race very purely; the admixture of Semitic and negro blood is not considerable. Their relatives are the Berbers of northern Africa and the Bisharis, Gallas, and Somalis, of eastern Africa. The evident relationship subsisting between Egyptian and the Semitic languages has given rise to several theories. Some scholars (e.g. Wiedemann and De Morgan) believe that the Egyptians and the kindred Hamitic races migrated in prehistoric times from Asia into Africa. Erman holds that at some remote period the Nile valley was invaded by Semites, who, though few in number, were able to conquer the country and to impose their language on the conquered people. According to this theory the Egyptians were, to use Erman's own expression, "Semitized Nubians." Other scholars (as Palgrave, Brinton, and Keane) hold that the ancestors of both Semites and Hamites emigrated together in northern Africa, when the latter emigrated at a very remote period into Arabia. A very clear summary of the whole argument is to be found in Barton, *A Sketch of Semitic Origins* (New York, 1902). The weight of evidence seems to be rather in favor of the last hypothesis. The Hyksos invasion led apparently to little intermingling of races, but under the New Empire there was some infusion of Semite blood, especially from the slaves captured in the Asiatic wars. Under the Twenty-second dynasty the Libyans contributed an important element to the population and the Ethiopians (dynasty Twenty-third) probably added some Nubian elements. The Assyrian rule was of a very temporary character, and neither this nor the Persian dominion affected the population appreciably. Under the Ptolemies there was a considerable influx of Greeks, especially into the Delta and the Fayum, and many Jews settled in the commercial cities. The Mohammedan conquest in the seventh century A.D. brought a large Arab population into Egypt, which later received additions from the Tatar Turks. In spite, however, of all this, the old type maintained itself with considerable purity, and the Egyptian fellow of the present day is the true descendant of his forefathers under the early Pharaohs. Consult Roeder, "Der ägyptische Stand der Aegyptologie," *Prähistorische Zeitschrift* (1912), pp. 419 ff.

Government and Administration. It has been conjectured that the nomes, or provinces, of ancient Egypt represent the remains of a number of independent states or tribes, which in course of time were brought together under a central authority. It is not improbable that such a condition actually existed, but, if so, it must have been at a very remote period of antiquity. Long before the beginning of the historical period Egypt had advanced to another stage of political development, and consisted of two kingdoms, the Delta and the South, with their frontier not far from Memphis. These two

kingdoms were united into a single monarchy before the time of the earliest monuments, but the memory of the union was preserved in the titles of the Egyptian kings down to the period of Roman dominion. As in other Oriental countries, the government of Egypt was, in theory at least, an absolute despotism; the will of the King was law. But in practice this was modified by various circumstances. At times, as in the Middle Kingdom, the great nobles became almost independent of the crown, and the central power was correspondingly abridged; and later the ecclesiastical power encroached upon the royal prerogative until it finally usurped the whole authority.

Under the Old Empire the government of Egypt was organized on the basis of a great bureaucracy. The various governmental departments, at the head of which stood that of the Treasury, were systematically arranged and there was a regular hierarchy of officials, each intrusted with definite duties and each directly responsible to his immediate superior. The government was administered by a Vizier or, at times, by two such officers representing Upper and Lower Egypt respectively. The nomes, however, occupied a somewhat peculiar position. Each nome had to a certain extent its own internal administration and a copy in miniature of the state. It had its own treasury, its own courts of justice, and its own militia. The nomarchs, or rulers of nomes, were the heads of ancient noble families possessing large landed estates and numerous special privileges. In the troubled period which followed the close of the Old Empire, the weakness of the central power gave rise to practically independent princes. In this way there arose a feudal system similar to that which prevailed in mediæval Europe. The nomarchs of the Middle Empire acknowledged the King as their suzerain, but they were no longer his servants. Amenemhat I, the founder of the Twelfth dynasty, was partly successful in his effort to curb the power of these haughty nobles; but he was never able to bring them into complete subjection, and they maintained their power and their privileges down to the time of the Hyksos War. But though the bureaucratic state of the Old Empire gave way to the feudal state of the Middle Empire, there was little change in the external form of the government, and the Treasury Department, at least, with its numerous and varied administrative functions, remained unchanged.

The Eighteenth dynasty established a new order of things. The old turbulent nobility had been swept away in the Hyksos wars, their estates had fallen into the hands of the crown, and the nomes were administered by royal governors. The feudal system of the Middle Empire gave way to a highly centralized military government. At the same time there was another important feature. Under the New Empire the priestly class rose greatly in importance. The immense booty derived from the Asiatic wars was lavished upon the temples, which at the same time acquired extensive landed estates. This was notably the case with priests of the god Ammon of Thebes, and the great wealth thus accumulated gave the Theban hierarchy so overwhelming an influence that they were at last able to overthrow the royal authority and to establish a priestly dynasty (the Twenty-first), ruling upon theocratic principles. In the meantime the

army, largely composed of mercenary troops, had gained in power and importance. Many of the chief offices of the state fell into the hands of military officials, and finally the Libyan mercenaries under Sheshonk drove out the priest kings, and established dynasty Twenty-two.

From a very early period the system of laws was highly developed, and the administration of justice played an important part in the state. Diodorus states that the Egyptians possessed sacred books of laws the composition of which they ascribed to the god Thoth, and that other laws were enacted by various monarchs. No collections of laws have been preserved, though a number of papyri give information as to legal procedure in particular cases, both civil and criminal. Each nome had its own court over which the nomarch presided. There were also under the Old Empire six courts of wider jurisdiction, known as the Six Great Houses, composed of high nobles with the Vizier at their head as chief justice. Under the New Empire the Vizier was still the chief justice by virtue of his office, but the institution of the Six Great Houses no longer existed. There were, however, district courts throughout the land. They were composed of certain high officials, and the Governor of the district usually presided. From the decision of these courts there was an appeal to the King. The judges were at all periods under the special protection of Ma't, the goddess of truth and right; they wore her image when on the bench, and many, if not all of them, were her priests. The punishments for crimes and misdemeanors varied in degree from beating upon the hands and feet or degradation from office or mutilation such as the cutting off of the nose, to death by one's own hand or by starvation.

Language. Egyptian belonged to the Hamitic family of speech, of which the principal modern representatives are the Galla, Somali, and Bishari of eastern Africa, and the Berber languages, of northern Africa. Egyptian itself shows an undeniable relationship to the Semitic languages, though it is not yet determined whether this relationship depends upon an early conquest of the Nile valley by Semites, or upon a primitive kinship between the peoples of the Hamitic and Semitic stocks. The oldest monuments of the Egyptian language go back to about 4000 B.C., and it did not die out as a spoken language until about three centuries ago. In the course of its long history it naturally underwent many changes. The language of the Old Empire, e.g., was no more intelligible to an Egyptian of the Nineteenth dynasty than Latin would be to the average Italian of the present day. Egyptologists distinguish the following chief periods of the language: 1. Old Egyptian, the classical language of the Old Empire. Long after it had ceased to be spoken it led an artificial existence as a learned language, playing much the same part as Latin played in mediæval Europe, and was regularly employed for religious and monumental purposes down to the Roman period. Careful philological training was not, however, a distinguishing characteristic of the Egyptian scribes, and therefore texts composed in Old Egyptian after 1000 B.C. are all bad imitations of earlier monuments: those written after 500 B.C. are barbarous. The best grammar of Old Egyptian is Erman, *Alt-ägyptische Grammatik* (Berlin, 1894; Eng. trans., London, 1894). 2. Middle Egyptian, the popular language of the Middle Empire. It rep-

resents an intermediate stage between the language of the Old and that of the New Empire. Most of the old forms and inflections are retained, but some of the peculiarities of the later speech begin to make their appearance. This stage of Egyptian is treated by Erman in his *Die Sprache des Papyrus Westcar* (Göttingen, 1889). 3. Neo-Egyptian, the popular language of the New Empire (about 1500-1000 B.C.). It is represented by a considerable number of papyri written almost exclusively in the hieratic character, and containing chiefly tales, poems, letters, and legal documents. This period of the language is exhaustively treated in Erman, *Neuägyptische Grammatik* (Leipzig, 1889). 4. Late Egyptian, the popular language in use from about 700 B.C. to the Christian era. It is often called demotic, but this is not strictly correct, since the term "demotic" properly designates, not the language of this period, but the script in which it is written. Late Egyptian is represented by a large number of papyri written in the demotic script. They contain chiefly legal and commercial documents, letters, and magical texts, together with a few tales. There is no good treatment of this subject. The best is by Brugsch, *Grammaire démotique* (Paris, 1855), but that is antiquated. 5. Coptic, the language of Christian Egypt and the latest descendant of Old Egyptian. It is written in a modification of the Greek alphabet with the addition of some characters derived from demotic, and in its vocabulary it has borrowed freely from the Greek. A number of local dialects may be distinguished. As a spoken language, it died out only about 300 years ago, and it is still employed as the ritual language of the Coptic church. Coptic possesses a considerable literature, which is almost entirely of a religious character and includes many translations from Greek works. The standard grammar of the language is Stern, *Koptische Grammatik* (Leipzig, 1880). Steindorff, *Koptische Grammatik* (Berlin, 1894), is, however, better adapted to the needs of beginners. Both Erman's *Neuägyptische Grammatik* and Steindorff's *Koptische Grammatik* contain useful bibliographies, which together cover all the periods of the language.

In Egyptian, as in the Semitic languages, triconsonantal stems prevailed, though even in the oldest texts many stems had been reduced by corruption to a biconsonantal scheme. Quadriliterals and quinquiliterals were formed, chiefly by partial reduplication. As in Coptic, each word had but one full vowel, which stood either in the penult or ultima. In closed syllables it was short; in open syllables it was long. The accent of a word rested upon the syllable containing the full vowel. As in Semitic, each word or syllable must begin with a consonant. The language possessed both independent and suffixed personal pronouns, which were employed much as in Semitic. The number of the demonstrative pronouns is considerable. In Old Egyptian there was no article: the definite article first comes into use in Middle Egyptian, and the indefinite article in Neo-Egyptian. In the substantive and in the verb two genders were distinguished—masculine and feminine, the latter standing also for the neuter. As in Semitic, the feminine ending of the substantive was *t*. There were three numbers—singular, dual, and plural, each distinguished by special ending, but the dual early became obsolete. The old inflection of the verb, formed by the addition of certain

pronominal endings to the stem, resembled the Semitic perfect apparently by difference of ctive-passive and a passive-intransitive form; but the former was almost obsolete at the time of the earliest texts. The later inflection was formed by suffixing a personal pronoun to a participial form. Both active and passive f Auxiliary verbs are four

in the later stages of the language they are employed with increasing frequency, and in Coptic, with the exception of a few survivals, conjugation by means of auxiliary verbs in combination with the infinitive or participle has entirely supplanted the older modes of inflection. A causative was formed by to the stem, and it is probable that conjugations may have existed at a very remote period. There are, at least, traces of a reflexive form with prefixed *n*, like the Semitic Niphal. The verb also formed a participle, an imperative, and an infinitive; the last named had both masculine and feminine forms and was treated like a noun. The genitive relation was originally expressed by simple juxtaposition, the accent, as in the Semitic construct connection, shifting to the second word. It was later expressed by means of a particle (originally a demonstrative pronoun) placed before the *nomen rectum*. The structure of the sentence was generally simple. The prevailing order was verb, subject, direct object, indirect object. This, however, might be modified by special circumstances. A pronoun, e.g., preceded a noun, and a word might be placed out of the usual order for the sake of emphasis. Consult, in addition to the grammatical works cited above, Sethe, *Das ägyptische Verbum* (Leipzig, 1899-1902), and Erman, "Die Flexion des ägyptischen Verbums," in *Sitzungsberichte der königlichen preussischen Akademie der Wissenschaften zu Berlin*, vol. xix (1900).

Writing. The hieroglyphic system of writing was believed by the Egyptians to have been invented by the god Thoth, who instructed the inhabitants of the Nile valley in its use. It is found fully developed on the most ancient monuments and continued to be used for monumental inscriptions down to the Roman period. The latest hieroglyphic inscription dates from the year 250 A.D. (See ESNE.) The individual characters or hieroglyphs are pictures of men, animals, plants, weapons, implements, and other objects. Their number is very large, though only about 500 are in frequent use. As regards their employment, they naturally resolve into three classes: 1. Phonetic signs, which are either alphabetic or syllabic; i.e., they stand either for a single consonant or for a syllable. 2. Ideograms, which properly represent each a particular word, but are frequently used, in a purely phonetic manner, to represent any word having the same group of consonants. 3. Determinatives, or signs placed after words to indicate their meaning in a general way. For example, verbs of motion were determined by a pair of legs; names of animals, by the picture of a hide with the tail attached. The determinatives were not pronounced, but merely served as an indication to the reader. The prevailing orthography required that each word should be written by means of its ideogram (if it had one), and to this was added an indication of the pronunciation in phonetic characters. Sometimes the whole word was thus spelled out. As

in all ancient systems of writing, except the Assyro-Babylonian cuneiform, only the consonants were written, the vowels being left for the reader to supply. (See **HIEROGLYPHICS**.) While the hieroglyphics were well adapted for monumental inscriptions cut in stone and lent themselves admirably to decorative effects, they were very unwieldy where rapidity was essential. At a very early period, therefore, another kind of script, called the hieratic, came into use for writing on papyrus. The same characters were used, but in a more cursive form; only the essential features of the were retained, and these were by a few strokes. Hieratic, therefore, differs from hieroglyphic writing in much the same way that our written letters differ from print. While this style is encountered as early as the First dynasty, there was a constant tendency to give the hieratic a more cursive form when applied to business and other practical purposes, and this tendency resulted, about 700 B.C., in the development of a new script, called the demotic, or popular, writing. Demotic was simply a very cursive script and was developed from hieratic just as this was developed from hieroglyphic writing. It was in general use for papyri of a secular character as late as the Roman period. The most recent demotic text dates from the fifth century A.D. Throughout all these changes the system of writing remained the same; it was merely the forms of the characters that were altered. All three for mally run from right to left, causes the direction could b second century A.D. the Egyptians seem to have realized the cumbrous nature of the demotic cursive script and attempted to write their language in the very simple Greek characters. These attempts resulted in the development of the Coptic alphabet of 31 letters, of which 24 were borrowed from the Greek alphabet, while the remaining seven, representing sounds for which the Greek alphabet had no equivalent, were derived from demotic. In addition to its simplicity this alphabet has the great advantage of expressing the vowels as well as the consonants. As the vowels are never indicated in the older system, Coptic becomes practically the only guide to the vocalization of all the earlier stages of the language.

Literature and Science. That the literature of the ancient Egyptians was very rich is evident from the remains of it that we now possess. The earliest examples of religious literature are preserved in the texts engraved in the pyramids of dynasties Five and Six at Saqqara and consist of magical formulæ designed to secure the welfare of the deceased in the future life. They have been published and translated by Maspero in *Recueil de travaux* (Paris, 1882 et seq.). A later collection of texts of a similar character is to be found in the *Book of the Dead*. (See **DEAD, BOOK OF THE**.) The great mass of Egyptian religious literature consists of imitations of, and extracts from, these collections. There were, moreover, many religious myths, though but few have been preserved. Plutarch gives a very full account of the myths relating to Osiris and his family in his *Περὶ Ἰσιδος καὶ Ὀσίριδος*, and a few legends of the sun god Rê are to be found on the Egyptian monuments. These are fully treated by Wiedemann in his *Religion of the Ancient Egyptians* (Eng. trans., New York, 1897) and Budge,

The Gods of the Egyptians (London, 1904). There were also a number of ritual texts giving minute directions in regard to the temple services. The rituals of the Theban divinities Ammon and Mut have been published in facsimile by the authorities of the Berlin Museum (*Hieratische Papyrus aus den königlichen Museen zu Berlin*, 1896-1901). Contrary to the expectations entertained before the decipherment of the hieroglyphics, Egyptian literature is Collections of moral maxims, resembling in many respects the biblical Book of Proverbs, seem to have been popular. Among the best known are the Proverbs of Ptah-hotep (Prisse d'Avennes, *Fac-similé d'un papyrus égyptien en caractères hiéroglyphiques, trouvé à Thèbes*, Paris, 1847) and the Prescriptions of Ani (Mariette, *Les papyrus égyptiens du musée de Boulaq*, Paris, 1872-77). All such works are, however, entirely practical in their object and present no abstract philosophical ideas. Egyptian science was also entirely practical and falls far short of the expectations raised by classical writers. The *Rhind Papyrus* of the British Museum, dating about 1600 B.C., is the most extensive mathematical work of the ancient Egyptians that has been preserved. Dr. August Eisenlohr published a facsimile of this papyrus, accompanied by a translation and commentary, under the title *Ein mathematisches Handbuch der alten Aegypter* (Leipzig, 1877), and a facsimile in colors was later issued by the trustees of the British Museum (London, 1898). Consult also Griffith, "The Rhind Mathematical Papyrus," *Proceedings of Society of Biblical Archaeology* (1891, 1894). It is a mere handbook containing the solution of a number of arithmetical and geometrical problems of practical application. How, e.g., to divide so many loaves of bread or so many jars of beer among a certain number of persons so that each shall receive a certain proportion; how to calculate the number of bushels of corn that can be contained in a granary of given dimensions; how to calculate the area of a field of given linear dimensions, etc. Notation for whole numbers was decimal, and all fractions except two-thirds were primary. Addition and subtraction were easily handled, but multiplication or division by any number larger than ten involved a very long and tedious process. Of the astronomy of the Egyptians little is known at present, though it is evident that they paid much attention to the subject. They mapped out the constellations, distinguished between planets and fixed stars, and constructed charts exhibiting the positions of the stars during the 12 hours of the night. The Egyptian year contained 365 days divided into 12 months of 30 days each, with 5 intercalary days added at the end of the year. From the earliest times great attention was paid to medicine, and the Egyptian physicians enjoyed a high reputation among the nations of antiquity. One extensive medical work, the *Papyrus Ebers* (see EBERS, G. M.), written about 1550 B.C., has been preserved and fragments of similar works have been found. Among the latter are portions of treatises on gynecology and veterinary medicine. (Consult Griffith, *The Papyrus Papyri*, London, 1898). Although embalming was practiced from very early times, the Egyptians never acquired much knowledge of anatomy. Their medical books are little more than collections of prescriptions, and it is evident

that their practice was altogether empirical. The remedies prescribed are often most repulsive, and the repetition of magical formulæ was believed to increase the efficacy of the medicaments employed. The belief in magic was universal in all periods of Egyptian history, and the literature on the subject is most extensive. It has been seen that the magical formulæ of the *Book of the Dead* and of older collections of similar import formed the bulk of Egyptian literature, and, in addition to these, numberless charms and incantations were devised for every conceivable purpose. A most interesting collection of these incantatory formulæ is to be found in the well-known *Harris Magical Papyrus* (Chabas, *Le papyrus magique Harris*, Châlon-sur-Saône, 1860). No collection of laws has been found, though there are many documents illustrating the civil and criminal laws of the ancient Egyptians. Among the most interesting and valuable of these are the *Turn Papyrus* (trans. by Renouf in *Records of the Past*, 1st series, vol. viii, London, 1879), containing a report of the in regard to a conspiracy against (see TURIN, Papyrus), and the *Abbot Papyrus* (trans. by Horrack, *Records of the Past*, 1st series, vol. xii), which contains a report of the of the tomb robberies in the reign of (about 1100 B.C.). Full accounts of these celebrated cases are given in Erman, *Life in Ancient Egypt* (New York, 1894). The poetry of the Twelfth dynasty formed the model for all periods; it somewhat resembles Hebrew poetry, employing the same parallelistic form, but is much inferior to it. The only epic poem that has survived celebrates the victory of Rameses II over the Hittites at Kadesh on the Orontes. It contains some spirited passages, but the action drags interminably, and the long and turgid declamations in which the King boasts of his superhuman prowess, are wearisome to a modern reader. The authorship of the poem has been erroneously attributed to a certain Pentaur; he was, however, merely the copyist of the manuscript (*Papyrus Sallier*, iii), which is published in the *Select Papyri of the British Museum*, part i (London, 1842). A translation of the poem by Lushington is given in *Records of the Past*, 1st series, vol. ii (London, 1875). In lyric poetry the Egyptians were more successful. There are many fine hymns, and the few love songs that have survived are graceful and pleasing, though they exhibit no great depth of feeling. Good examples of the former are to be found in Wiedemann, *Religion of the Ancient Egyptians* (New York, 1897); the love songs are collected in Maspero, *Études égyptiennes* (Leipzig, 1879), and are more fully treated in W. Max Müller's *Die Liebespoesie der alten Aegypter* (Leipzig, 1899).

In their literature the Egyptians excelled all other Oriental nations of antiquity. While, however, it preserves various tales for us, it is lacking in much literary value. Its style is stilted and artificial and makes use of many repetitions. Its poetry lacks rhyme and, so far as our knowledge permits judgment, did not possess rhythm. From the earliest times they delighted in tales and stories, and the professional story teller was as familiar a figure in ancient Memphis and Thebes as he is to-day in the bazars of Cairo. Many of these old Egyptian tales have been preserved and are accessible to modern readers in excellent translations. It

is, of course, natural that such stories should attach themselves to famous historical personages of former days, and this is the case with the *Papyrus Westcar* (Erman, *Die Märchen des Papyrus Westcar*, Berlin, 1890), a collection of stories dating from the time of the Middle Empire. In this collection King Cheops is represented as suffering from insomnia and calling upon his sons to entertain him with stories. We here recognize the earliest example of the familiar literary device, often employed in later times, whereby a number of persons are brought together by some special occasion which furnishes a motive for story telling. The princes obey their father's command and narrate, in turn, tales of the wonders wrought by famous magicians. One of these magicians constructs a small crocodile of wax, which, when thrown into the water, attains a formidable size and seizes the lover of the magician's faithless wife. Another by his incantations lays bare the bed of a lake and recovers a jewel lost by a lady of the court, after which he returns the water to its former place. When the turn of Prince Hardadaf comes, he tells of a wonderful magician then living and is commanded to bring him to court. The magician, after giving some marvelous proofs of his skill, predicts that the wife of a certain priest will shortly bear to the sun god Rê three children, who will establish a new dynasty in Egypt. The narrative then passes to the birth of the children and the marvels by which it was attended. Unfortunately the manuscript is incomplete, and the end of the story is lost. The tale of the *Fated Prince* (*Papyrus Harris*, No. 500) is based upon a motive familiar in the folklore of many peoples. A prince is born, and at his birth it is predicted that he will die by a crocodile, a serpent, or a dog. To prevent the accomplishment of the prediction, his father causes him to be brought up in an inaccessible castle, where he is carefully watched and tended. Attaining manhood, the prince refuses to remain thus imprisoned and sets forth into the world to seek his fortune. He meets a princess whose watchfulness saves him from the serpent, and his faithful dog comes to be the means of his deliverance in his combat with the crocodile. But here the manuscript breaks off, and we are left in doubt as to whether he succumbs to the third fate or is delivered from this also, perhaps by the interposition of some deity. The well-known *Tale of the Two Brothers* (*Orbiney Papyrus*) is fortunately preserved entire. In this tale two brothers live affectionately together until the wife of the older falls in love with the younger and tempts him. He rejects her offer of love, and in revenge she kills her husband, who seeks to kill the younger brother. The younger brother flees from his home and takes up his abode in a solitary place. The gods, pitying his loneliness, fashion a woman of surpassing beauty to be his wife, but she, too, proves faithless. A lock of her beautiful hair is borne by the sea to the King of Egypt, who sends his messengers, and she readily allows herself to be carried off. Her husband is slain, but is miraculously restored to life and, after a series of wonderful adventures, becomes King of Egypt and punishes his faithless wife with death. In addition to the wonders of magic, travel and adventure in strange lands formed a favorite theme of the Egyptian story tellers. The story of the shipwrecked mariner, a sort of Egyptian

Sindbad, who is cast upon a fabulous island peopled with serpents, and the legend of the taking of Joppa by the General Tahuti, who contrives to introduce his men into the town concealed in sacks of grain, are good examples of this kind of narrative. In all these stories the style is simple and unaffected, and the interest lies entirely in the development of the plot. Of an entirely different type is *The Story of Sinuhe* (Lepsius, *Denkmäler*, vol. vi, Leipzig, 1858), an Egyptian of high rank, who flees his country on account of some political complication and takes refuge with the Syrian Bedouins. He is kindly received, vanquishes a redoubtable champion in single combat, and is advanced to high honor. But after a prosperous life among the Bedouins he yearns in his old age for his native land and applies to the Pharaoh for permission to return to Egypt. His request is granted, and on his return he is restored to all his former wealth and honors. In this story the plot is extremely simple, while the style is ornate and florid, and the narrative is loaded with rhetorical embellishments. Of a similar character is the story of the *eloquent Peasant* (Lepsius, *Denkmäler*, vol. vi, Leipzig, 1858). The peasant is robbed of his ass and applies to the chief official of his district for redress. His eloquence excites the admiration of the official, who reports the matter to the King, and by his command the case is carried on from term to term, the peasant's speeches being carefully written down and reported to his Majesty. Here the very slender thread of narrative merely serves to carry the semipoetical speeches of the peasant, which, for the ancient reader, constituted the real charm of the book. It would seem that these very elaborate compositions were intended for a more cultured circle of readers, while the tales of magic and wonderful adventures reflect in their simple style the stories current among the people. The rhetorical narrative belongs, moreover, to a particular period, that of the Middle Empire. Although still cultivated to some extent by the learned, especially for educational purposes, it seems to have gone out of fashion under the New Empire, and thereafter Egyptian taste affected the simpler tales of magic and adventure. One of the latest romances that have been preserved is the tale of *Setna Kha-em-Wa'st* (Hess, *Der demotische Roman von Setna Kha-em-Wa'st*, Leipzig, 1888) found in a demotic papyrus of the Ptolemaic period. The hero, a son of King Rameses II, devotes himself to the study of magic and descends into an ancient tomb to obtain a wonderful book of enchantment written by the god Thoth himself. He secures the book, but its possession brings unhappiness, and he is at last compelled to restore it to its place and to make expiation for having removed it. The plot of this tale is well constructed, the action advances rapidly, and the incidents are varied and wonderful. But although it is in some respects a more elaborate composition than the tales of the older period, the style is simple and shows no trace of the straining after effect which characterizes the rhetorical narrative of the Middle Empire. Translations of such old Egyptian tales as have been preserved are given in Maspero, *Les contes populaires de l'Égypte ancienne* (Paris, 1889), and in Perrie, *Egyptian Tales* (London, 1895-99). The best translations from the various departments of Egyptian literature are to be found in *The World's Best Literature* (ed.

Ancient Religion. The religion of ancient Egypt had its origin in a low kind of fetishism, or animism, of purely African character. Every village of prehistoric times seems to have had its own god or demon, worshiped in some object, usually a tree or an animal. Out of this endless pantheon, in course of time, only the "great gods" survived, i.e., those of the principal cities. The most important deities of the surrounding places were brought into relation with the god of a city by his "circle of gods," i.e., his wife, etc.; thus, most of the deities are surrounded each by his "circle of gods." The worship of the celestial bodies, principally of the sun, developed early, but was connected with the leading cults, so that the sun never had one name throughout all Egypt. The earliest forms seem to be Ré and Horus, whom the theologians differentiated as the midday sun and the young morning sun respectively (both worshiped in hawk form). In the earliest texts, however, we find Heliopolis in possession of its own sun god, Atmu, in whom the later theological system saw the old setting sun. Osiris (the local god of Abydos and Busiris) also became the setting sun, ruling the lower heavens. In short, sooner or later, almost every local divinity was treated as a form or phase of the sun. The confusion which existed even in the earliest religious documents cannot be described. The Egyptian priests, of course, felt this confusion, but their attempts to construct a logical system were of little avail. Their genealogies of the gods, their identification of all similar deities, who were explained as different manifestations of the same deity, their division of the world and of the natural forces among the various gods of the pantheon, were contradictory and merely served to increase the confusion. Amenophis IV endeavored to carry the identification of the various divinities to its logical conclusion and to establish a species of monotheism, in which the sun was worshiped as the supreme source of life and power. But although Amenophis carried on his propaganda by imperial violence, the attempted reform did not survive his own reign. The highest development of the later religion, arising from the identification of all divinities, led to pantheistic ideas after 600 B.C.; but these advanced thoughts did not touch the popular religion, which always remained attached to the old fetishistic local cults, to the worship of animals, etc.—to those features, in fact, which were so unintelligible to the Greeks that they sought to explain them as veiling higher ideas under a mysterious symbolism. The ibis Thoth (Dhonti) of Hermopolis became a moon god and the father of science and letters, like the Greek Hermes, whom he also resembled in his function as leader of the dead. Ptah of Memphis was one of the creators of the world, being a craftsman and artist (like Hephaestus). The cow-formed Athor of Denderah eventually became the goddess of love. Ammon of Thebes, after 1600 B.C. the chief god of Egypt, is, of course, a sun god; his wife Mut becomes the sky, and their child Khonsu the moon. At Eleithyria was revered the goddess Nekhbet, whose counterpart for Lower Egypt is Buto; at Bubastus, the cat Thabet was worshiped; at Sais, the Libyan goddess Neit; in the Fayum, the crocodile Sobk (Souchoa). The ithyphallic

harvest god Min was worshiped at Chemmis and Coptos; at Elephantine, the ram Khnumu (Chnuphis) and the goddesses Anuket and Satet. Under the New Empire many Semitic gods were introduced and became very popular: Baal, Astarte, Anat, Kadesh, Rashpu (lightning), etc. The cult of some gods can no longer be localized; e.g., that of the beetle Khepre, another creator of the world and sun god; that of the good dwarf Bes, the patron of the dance, of music, and of female dress; that of the equally benignant female hippopotamus Tuêris, etc. The principal animals worshiped as gods were the bulls Apis at Memphis, Mnêvis at Heliopolis, and Bachis at Hermonthis, the goat at Mendes, etc. These were all incarnations of local gods. Different is the general sacredness of an animal from a divinity; thus at one place all cats were sacred, at another all dogs. It occasionally happened that in one locality an animal was proscribed and persecuted, while in the neighboring town it was held sacred, as, e.g., at Bahnasa (q.v.).

Egyptian mythology seems to have been very rich; legends of the gods were attached to every sanctuary, and the priests played the part of gods, were given at the local festivals. Allusions to these legends are to be found in the religious texts, but details are wanting. Of all the great mass of legends and myths, only the myths relating to Osiris and his family and a few legends of the sun god Ré have survived. Osiris, originally the local god of Abydos and Busiris, was one of the many deities who in course of time acquired a solar character. He was especially identified with the setting sun, ruling the lower heavens and the mysterious region below the western horizon. He thus came to be regarded as the god of the realms of the dead, and his worship became popular throughout the land. In Egyptian mythology Osiris was the beneficent ruler of mankind, who elevated his subjects from barbarism and taught them the arts of civilization. He, however, incurred the enmity of his wicked brother Set, by whom he was treacherously murdered. His body, inclosed in a chest, was cast into the Nile and floated out to sea. Isis, the sister and wife of Osiris, after a long search found her husband's body and buried it; but it was disinterred by Set, who cut it in pieces and scattered the fragments far and wide. Isis searched out all the pieces and buried them separately. In the meantime Horus, the young son of Osiris and Isis, grew to manhood and avenged his father by defeating his murderer in a terrific combat. Osiris, though dead on earth, lived in the under world and became the ruler of the dead. His sister and wife Isis may be identified with the constellation Virgo, and their child Horus is the young morning sun. Osiris has another sister, Nephthys, who is married to his brother and murderer Set (Typhon). The jackal Anubis (q.v.), the guardian of the lower world and the patron of embalmers, is the son of Osiris and Nephthys. Set may have been originally the constellation Ursa Major; he then became the personification of every force of nature opposed to the sun, the prime mover of all disorder and violence. He thus came to be a god of war and, after 1000 B.C., a sort of Satan. Every evening he cuts Osiris in pieces (the stars), which Isis unites every morning. The parents of the hostile gods are Seb (or Gêb) and Nut—earth and

heaven. The parents of these are Shu (Shou) and Tefnut (perhaps ether and moist air), while the father of all the gods is Nu (later erroneous form, Nun), the primeval abyss. The Osirian myth is very fully treated by Plutarch in his *Περὶ Ἰσίδος καὶ Ὀσίριδος*, and the general accuracy of Plutarch's account is attested by numerous allusions in the Egyptian texts. The legends of the sun god Rê are derived from monumental sources. According to these legends Rê, in primeval ages, and after deposing the powers of darkness assumed the government of the world. He reigned long and peacefully, but finally grew old, and his powers failed. The wise goddess Isis took advantage of his weakness to gain a long-cherished wish. She was deeply versed in magic and in all hidden and mysterious things, but one thing was wanting—she did not know the secret name of Rê, upon which his power was founded. In order to learn the secret she had recourse to a stratagem. Taking some of the god's saliva, she kneaded it with earth and formed a poisonous serpent, which she placed in the path along which Rê was wont to walk. As the god took the air with his attendants, the serpent stung him, and the poison caused him intense pain. He called upon all the gods for aid, but none could relieve him save Isis, and she would heal him only at the price of his secret name. For a long time Rê held out, but finally, no longer able to endure the torment, he revealed the secret and regained his health through the magic powers of Isis. His vigor was, however, impaired, and even men dared to rebel against him. In his anger he called a council of the gods, in which it was decided to send the goddess Athor to destroy all mankind. In the night Athor descended to the earth and began such a fearful slaughter that blood ran in rivers, and even the gods were appalled. Rê determined to stop the massacre. He caused beer to be prepared and had it poured out at evening so that it overflowed the fields. In the morning the goddess, drinking copiously of the beer, became drunk and was unable to recognize mankind. Rê was now weary of rule, and he retired to rest in heaven, leaving the god Thoth as his deputy upon earth. Consult, in regard to Egyptian mythology, Wiedemann, *Religion of the Ancient Egyptians* (Eng. trans., New York, 1897), and Erman, *Life in Ancient Egypt* (Eng. trans., London, 1894).

It was at all times a deeply rooted belief of the ancient Egyptians that man possessed a spiritual part which continued to exist after death, although the precise nature of this existence was never very clearly defined. They regarded the human person as consisting of at least three parts: the *khat*, or body (*khat*); the living soul (*ba*); and a sort of spiritual double, or ghost, which was called the *ka*. The *ba*, or soul, seems to have represented the vital principle: but it had other functions which are by no means clear. After death it was supposed to leave the body in the form of a bird, usually represented with human head and hands, and to fly up to the gods in heaven. The *ka* was an independent spiritual being, living within a man and representing his human personality both during life and after death. It was his inseparable companion during life, and after death it hovered around his mortal remains. At times it could enter and reanimate the body; it was necessary, therefore,

to preserve the body in such condition as to be always tenable by its spiritual visitor. To this end it was incumbent upon the relatives of the deceased to have his body as carefully embalmed as their means would allow and to place it in a tomb where it would find protection from all accidents. But although separated from the body, the *ka* still experienced hunger and thirst and other human needs. It was therefore necessary to provide food and drink, books, games, and such household effects as would secure the comfort of the *ka* in the tomb. It was not absolutely required that material food and drink should be supplied. Magical formulæ recited over the body or inscribed upon the tomb insured to the deceased the enjoyment of "thousands of bread, beer, oxen, and geese." Such formulæ were always repeated at the funeral by the reciter priest, and the inscriptions constantly adjure visitors to the tomb to repeat these important words.

The *ba* and the *ka* existed in the individual during life and continued to live as separate entities after death. But when life departed from the body, the spiritual personality of the deceased assumed a new form, known as his Osiris. Of what elements this spiritual counterpart of the deceased was made up is not explained, and the Egyptians themselves seem to have had very vague and confused notions upon the subject. So much, at any rate, is clear, that just as Osiris died and lived again, so the spiritual personality of the deceased lived again and was merged in Osiris, or rather it became Osiris himself. As to where and how the individual lived after death, various ideas were entertained. He was supposed to find a home among the stars, to sit like a bird on the branches of trees, to hover around his mummy in the tomb, or to appear upon earth in various transformations. According to the most widely prevalent belief, however, the defunct was conducted by the god Anubis to the realm of the dead, where he had to undergo judgment before Osiris, the King of the Lower World, and 42 Assessors, of strange and monstrous form. The path was beset with difficulties and dangers, gates had to be passed which opened only to those who knew the proper password; demons lay in wait to seize upon unwary souls; lakes of fire must be traversed; and many other obstacles lay in the way. But if the deceased were provided with the appropriate formulæ of the *Book of the Dead*, he surmounted all these difficulties and finally entered the judgment hall. If the judgment was adverse, he was cast into a fiery lake, or given over to be devoured by a hideous monster. If, however, the judgment was favorable, the defunct was assigned an abode in the Elysian Fields and enjoyed a perpetual banquet at the table of Osiris. If, moreover, he knew the proper magical formulæ, he could come forth upon earth and assume any shape he pleased; he traversed the heavens in the boat of Rê and Horus and shared in their triumph over the powers of darkness; all earthly impurities were washed away, the divine portion alone remained, and he became a god. In the course of the final judgment the deceased was obliged to present himself before each of the 42 judges in turn and declare himself free from a particular sin. This constituted the celebrated "Negative Confession," which is to be found in chapter cxxv of the *Book of the Dead*. It indicates the existence of a high standard of morality and is

thoroughly in accord with the teaching of the moral papyri and with many funerary inscriptions in which the particular virtues of the deceased are detailed. It was not, however, necessary that the deceased should be actually guiltless of all the sins; it was only necessary that he should declare himself innocent of them, and, above all, that he should name the names of the infernal judges. If he knew the proper chapter of the *Book of the Dead*, or even if it were written out and placed in his coffin, he had nothing to fear.

It is sometimes assumed that the Egyptians looked for a general resurrection of the dead and for a great day of judgment, when all mankind must answer together for the deeds done in the flesh. Of this, however, the evidence is far from satisfactory, and it would rather seem that each individual underwent judgment and received his reward or punishment shortly after death. Consult: Wiedemann, *The Ancient Egyptian Doctrine of Immortality* (New York, 1895); Erman, *Life in Ancient Egypt* (London, 1894); Bridge, *The Gods of the Egyptians* (ib., 1904); Steindorff, *Religion of the Ancient Egyptians* (New York, 1905); Wiedemann, *Religion of the Ancient Egyptians* (ib., 1897); Maspero, *Etudes de mythologie et d'archéologie égyptienne* (Paris, 1893). Brugsch, *Religion und Mythologie* (Leipzig, 1884-88), is full, but not critical. For illustrations, consult Lanzzone, *Dizionario di mitologia egizia* (Turin, 1881-88). Champollion, *Panthéon égyptien* (Paris, 1825), is useful.

Manners and Customs. The wonderful fertility of the Nile valley has been famous in all ages, and under normal conditions the produce of the soil has always sufficed to support a dense population and to leave a large surplus of commodities for export. Agriculture was the source of Egypt's wealth and probably the most important factor in the development of her civilization. Under these circumstances it was natural that social conditions were largely determined by the ownership of land. In the time of the Old and Middle empires the land was, with exception of the crown domains, in the hands of a limited number of noble families. Neither at this time nor at any subsequent period is there any trace of a free peasantry. Throughout all ancient Egyptian history the agricultural laborer was a serf, and the condition of his modern representative, the Egyptian fellah, is hardly better.

The monuments of the older period, erected without exception by wealthy nobles, have little to say in regard to the existence of a middle class; but that such a class existed can hardly be doubted. The splendid creations of the art and architecture of the Fourth and Fifth dynasties postulate the existence of a class of artists and artisans who could plan and carry out such works. While textile fabrics might be produced by the peasant women on large estates, other manufactures required the existence of a manufacturing class. And finally, in the cities at least, there must have been merchants who handled the produce of the soil and articles of necessity and of luxury. Under the New Empire the agrarian conditions were very different. The old noble families were exterminated or impoverished in the Hyksos wars, their lands came into the possession of the crown, and large estates eventually fell to the share of the temples. The agricultural serfs merely changed masters and

were oppressed pretty much as before; but the new conditions favored the rise of the middle class, who now came into much greater prominence and even held important offices in the government and in the hierarchy. The Greek accounts of the division of the people into priests, warriors, and several other classes, each containing a number of subdivisions, must not be taken too literally and are far from proving that castes like those in India existed. It seems to be true that all occupations were highly specialized and thus divided into a number of branches; it is also true that Egyptian conservatism very much caused a son to adopt his father's occupation. But there was never any restriction in regard to the choice of an occupation or against the intermarriage of classes, except in so far as such matters were affected by those social prejudices which have existed at all times among all peoples.

At the head of the whole social organization stood, of course, the King, who was not merely the supreme ruler, but the direct descendant of the sun god Rê and therefore entitled to divine honors. After his death he was worshiped as a god. His principal wife, the Queen, was of royal birth or descent and not infrequently the sister of her husband. Such a marriage was regarded by the Egyptians as highly important, since the issue inherited a double portion of the divine blood of Rê. The Queen shared in all the honors of her husband and, if she survived him, still possessed high influence at court, especially if she were the mother of his successor. From motives of policy Egyptian kings often married foreign princesses; but these ladies never stood upon the same footing as the Queen; they were all subordinate wives, but one step higher than the other ladies of the harem. In the time of the Eighteenth dynasty an Asiatic prince sent, as a gift for the harem of Amenophis III, his eldest daughter, accompanied by 517 beautiful damsels. It is therefore not surprising that the Egyptian kings should have a large posterity. Ramesses II is said to have had 200 children, and of these, 111 sons and 59 daughters are mentioned in the inscriptions of their father. At the court great state and ceremony were maintained, and when the King appeared in public on ceremonial occasions he was attended by an army of courtiers, priests, bearers of the royal insignia, fan bearers, officers of the household, and many other officials of various grades.

Under the Old and Middle empires the wealth and power were in the hands of the nobles. The heads of the great families were the nomarchs, who possessed large landed estates and, with their relatives, filled all the higher offices of court and state. In the time of the Fourth and Fifth dynasties the monarchs seem to have preferred the neighborhood of the court; but under the feudal system of the Middle Empire they usually resided on their estates, where they lived in princely style. In addition to his private property the ruling nomarch enjoyed the revenue of the "house of the prince," which means the emoluments attached to his office arising from certain taxes and other sources of income. He was also, by right of birth, a member of the priestly college of the local temple and was usually its head. Under the New Empire, though most of the old titles were retained, the offices were chiefly filled by priests and military officers. The nomarchs were no longer feudal princes, but government officials who

could be appointed or removed at the pleasure of the King or his advisers.

Before the time of the New Empire most of the nobles and high officers of state bore priestly titles and exercised priestly functions. They monopolized, in fact, all the high offices of the priesthood, although it is probable that in most cases their duties were light and that they were only required to officiate upon certain stated occasions. The regular religious services were carried on by lower orders of priests, whose emoluments were not large and who seem to have occupied rather a subordinate position in the social organization. In addition, there were brotherhoods of so-called "hour priests," composed of pious laymen, each of whom devoted a portion of his time to the temple service, while the whole body took part on certain special occasions. These brotherhoods disappear under the Middle Empire.

The great wealth lavished upon the temples by the monarchs of the Eighteenth and subsequent dynasties brought about a very different state of affairs. The temples became great corporations, possessing immense landed estates administered by their own officials and worked by their own serfs. The power wielded by the heads of these religious houses was very great, and the position of the whole priesthood was elevated in a marked degree. Apart from the material influence given them by their wealth and political power, the priests were the exclusive custodians of the higher learning and exercised a profound influence upon the minds of the superstitious Egyptians, by whom they were credited with the possession of magical power. The priests were divided into a number of classes, according to their several functions; all classes were bound to observe scrupulous personal cleanliness, and in token of this they wore pure white linen garments and shaved their heads.

Until the New Empire there was no distinct military class. Each nome had its own militia, and the nomarch was bound to furnish a certain contingent in time of war. But the Egyptians were never a warlike people, and hence from the earliest times they depended largely upon foreign mercenaries. First Nubians, later Libyans, were employed. Under the New Empire the army was of vastly greater importance; some of the highest offices of the state were held by military men, and the army vied with the priesthood in political influence. At a later period in military families, who were generally of foreign origin, the connection with the army was commonly inherited, together with the field given by the government as a fief for service. See paragraph on the Egyptian army under the title **ARMIES**.

The chief occupation of the Egyptians has always been agriculture. Wheat, barley, and durra (black millet) were the staple crops; but vegetables and fruits, such as onions, cucumbers, melons, grapes, and figs, were also extensively cultivated. The husbandry employed was rather crude and primitive. The soil was broken with a wooden plow drawn by oxen and was laboriously worked with a heavy wooden hoe. After the seed was scattered, flocks of sheep were driven over the freshly sown field to trample down the soil. At the time of harvest durra was pulled up by the roots, but other grain was cut with a short sickle. On the threshing floor the grain was trodden out by

the hoofs of animals; under the Old Empire these were usually donkeys, while in the time of the New Empire oxen were used for this purpose. After threshing, the grain was passed through a coarse sieve and was then winnowed by tossing it in the air with small wooden hand shovels. It was then measured by the scribes and stored in the granaries. Cattle raising was extensively carried on from very early times. Under the Old Empire there were still many marshy tracts in Upper Egypt which furnished excellent pasturage, and at all times the Delta was a fertile pasture ground. Much attention was paid to the improvement of the stock, and the finest bulls were always reserved for breeding purposes. Goats and sheep were raised in great numbers. The donkey was the ordinary beast of burden, although oxen were also used. Horses are first represented on the monuments of the Eighteenth dynasty; they were usually harnessed to chariots for war or for traveling, but were rarely ridden. Stallions were preferred to mares, and geldings do not seem to have been used until a very late period. Camels are not represented on the monuments before the time of the Ptolemies.

The Nile was the great highway of travel and traffic and with its numerous canals gave easy access to all parts of the country. Timber was scarce, and the smallest boats were flat-bottomed skiffs constructed of bundles of papyrus reeds bound tightly together; they were propelled by poles or paddles, according to the depth of the water. Larger vessels were built of wood obtained from Nubia. These were also flat-bottomed and had the stern of the modern Nile boat, in which the stern has considerably more overhang than the bow, so that, should the vessel run on a sandbar, the bow could be lifted off by throwing the weight astern. These boats varied considerably, according to the use for which they were intended. Freight vessels were broad and clumsy, while war vessels and boats intended for speed and recreation were often beautifully decorated. In addition to the oars, they were usually provided with a large square sail attached to a yard. It was at the time of the New Empire that a second yard, at the foot of the sail, was added. Both yards had braces and sheets for trimming the sail. The sheets, halliards, and standing rigging were all made fast inside of the hull. War vessels sometimes had a crow's nest on top of the mast, for a lookout or for archers. Large steering oars supplied the place of the rudder. But though they were at home in river navigation, the Egyptians were always disinclined to maritime enterprises, and therefore the carrying trade of the Mediterranean remained in the hands of the Phoenicians, while the infrequent expeditions of Egyptian ships down the Red Sea to the Somali coast (see **PORTS**) did not result in the establishment of extensive traffic in that direction. In the south a very important trade was carried on with Nubia, and trading posts were early established at Syene and Elephantine (q.v.), where panther skins, ebony, ivory, and ostrich feathers were bartered for Egyptian commodities. To the north a considerable trade was carried on by caravans with Syria and other Asiatic countries. While there is little to tell us how trade was transacted, commerce was probably conducted by barter, and in the early period money of any sort seems to have been unknown. Under the

New Empire metal rings were used as currency, a copper wire of given weight serving as unit. Although Egypt was chiefly an agricultural country, her manufactures were important and were early developed. Linen was extensively manufactured, and the finer grades of the ancient Egyptian linen cannot be surpassed in modern times. The papyrus plant furnished material for several industries. Bundles of papyrus reeds took the place of wood for the construction of small boats, and from the twisted fibres sandals, ropes, mats, sails, fishing nets, and other objects were made. The most important use of the plant was, however, in the manufacture of paper. For this purpose the stalks were cut into thin strips, and a layer of these strips was placed upon a flat surface. Over this a second layer was placed at right angles to the first layer. The leaf thus formed was pressed out into a thin sheet, to which the natural gum of the plant gave a homogeneous character. The sheets were then dried and were ready for use.

In the working of leather the Egyptians were very skillful. The coarser leather was used for the soles of sandals and shoes; from the finer grades were made aprons, belts, coverings for chairs and sofas, harness, chariot trappings, bow cases, and many other objects. Fine colored leather was stamped with ornamental patterns.

Clay is to be found in all parts of Egypt, and the potter's art was very early developed. The Egyptian earthenware was made upon the potter's wheel and was usually of a very simple character. For ornamental purposes, however, the Egyptians knew how to prepare a glazed ware resembling faience, and of this they made statuettes, vases, beads, and other small objects. Glass was produced at a very early period, and glass blowing is represented in pictures of the Middle and New empires. The Egyptian artisans were proficient in metal working, although metals had to be imported and were therefore scarce. Tools and weapons of the earliest period were made of copper, later of bronze. Iron, although known from very ancient times, was always scarce and was therefore not extensively used. Silver was in earlier times more valuable than gold; but under the New Empire it became more plentiful, and the relative values of the precious metals were reversed. An amalgam, corresponding to the *electron* of the Greeks, and containing two parts of gold to three of silver, was much used for jewelry and ornamental purposes. The great skill of the Egyptian goldsmiths and jewelers is exhibited in many specimens of their art that have been found in the tombs. They were adepts in the use of enamels, which were beautifully colored, and they made skillful imitations of precious stones in paste.

For building purposes and for sculpture the Egyptian quarries furnished an ample supply of stone of various kinds. From the quarries of Turah, nearly opposite Memphis, came the fine white limestone, which was used for mastabas, pyramids, and statues, and alabaster was obtained in the same neighborhood. Sandstone was obtained from the quarries near Gebel Silsileh, and near Assuan was quarried the beautiful red granite used for obelisks, columns, statues, and doorways, and for other architectural and artistic purposes. In the Wadi Hammamât was quarried the black granite used for statues and sarcophagi. Although working with inferior tools, the Egyptian artisans

handled the hardest stones in a manner unsurpassed in modern times. Their cutting was done with a small metal chisel and a wooden mallet, and they obtained a fine polish by rubbing with pieces of quartz or with quartz dust.

As a building material, stone was chiefly used for the construction of temples, tombs, pyramids, obelisks, and other monumental monuments; private houses were built of bricks made of Nile mud. The dwellings of the poorer class were generally mere hovels; those of the wealthy were often of considerable size and contained many rooms. The framework was of timber, and at the entrance there was often a columned portico. In some examples represented on the monuments the roof is raised above the upper story by small pillars, and the spaces between the pillars are left open to secure free ventilation. In others an awning is stretched over the flat roof, which was apparently the favorite resort of the family. Country houses were surrounded by gardens with beds of flowers, alleys of trees, and artificial lakes.

The Egyptians were not a grave and philosophical people; on the contrary, they were gay and cheerful. They were fond of amusement, and their frequent social entertainments were enlivened by the performances of musicians, dancers, and jugglers. Women as well as men were guests at these feasts, which were not always of a very sober character. As a people, the Egyptians were much addicted to the use of beverages. Beer was the national beverage. Beer was brewed from barley malt, and several kinds of beer are mentioned in the inscriptions. Wine also was largely consumed, and the Egyptian vineyards produced both red and white wines in abundance.

Of the many games mentioned or depicted on the monuments, the game of draughts appears to have been most popular. It was believed to form the favorite recreation of the blessed dead in the Lower World, and many draught boards have been found in the tombs.

At all times the Egyptians took great delight in field sports. The marshes were well stocked with aquatic birds, which the sportsman, pushing among the reeds in his skiff, brought down with a throw stick. Angling with rod and line and the spearing of fish were also favorite amusements. Larger game, especially the antelope, was hunted with hounds in the Libyan Desert, and lions were often killed in the same locality. At the popular festivals a favorite sport was the water tournament, in which the contending boatmen stood in their skiffs and sought to push their opponents overboard with long poles. Wrestling and cudgel play were also features of these occasions, and such contests were often so earnest that the defeated contestant had to be carried from the field.

In ancient Egypt women enjoyed a much greater degree of independence than in other countries of antiquity. They appeared with their husbands at social entertainments and took part in religious ceremonies. There were regular orders of priestesses attached to the service of the gods, and under the New Empire the priestesses, or "singers," of Ammon of Thebes were a very important body. At the head usually stood the Queen, and the lower grades were composed of the wives and daughters of priests, officials, military officers, and even artisans. The Egyptian law secured to women the full enjoyment of the rights of prop-

erty. A married woman, e.g., could hold property at her own separate disposal and could even lend money on interest to her husband. Polygamy was allowed, but was rarely practiced; as a rule, there was but one legitimate wife, who held a most honorable position in the household and had the direction of domestic affairs. A man might also have as many concubines as his means would allow, but extensive harems were a luxury of the rich. The Egyptians usually married young, and their large families were a source of wonder to the Greeks.

At the higher learning was in the hands of the priests, education was rather widely diffused, and reading and writing were common accomplishments, even among the lower classes. Schools existed throughout the country; they were usually attached to the various governmental departments, and, under the New Empire at least, graduation in these schools opened the way to admission into the civil and military service of the state. The school discipline was severe, and the rod was freely administered. "The ears of the young," says the Egyptian proverb, "are placed on the back, and the boy hears when he is flogged." At first the young pupil was taught to form the characters on potsherds, papyrus being too expensive for this purpose. When he acquired some skill in writing he was set to copying moral maxims like our old-time copy-book texts, and as he advanced he copied longer extracts and finally complete texts which were selected for their matter and style. The moral papyri containing rules of conduct and of manners were commonly used for this purpose; but poems, tales, and religious texts were also assigned. In this way the student, as he gained skill with his pen, became acquainted with the best works of the national literature. Much attention was given to the formation of a good epistolary style, and to this end students were required to copy out collections of model letters upon various subjects. Arithmetic and bookkeeping were important branches of study, and under the New Empire instruction in geography seems to have been given. Throughout the course the pupil was carefully trained in ethics, in the practical philosophy of everyday life, and in good manners. The more advanced instruction was, of course, adapted to the career in life which the particular student expected to follow; but little is known as to the manner in which it was imparted.

In the care bestowed upon the dead the Egyptians surpass all other peoples of ancient or modern times. The means adopted were more or less elaborate in proportion to the wealth of the deceased's family, but the principle was the same in all cases. The body was first embalmed (see EMBALMING) and, after being swathed in linen bandages, was placed in the coffin. In the time of the Middle Empire magical texts (see DEAD, BOOK OF THE) designed to protect the deceased from the perils of the Lower World were inscribed upon the coffin boards. Under the New Empire similar texts were written upon papyrus and placed within the coffin. Amulets of various kinds were placed beside the mummy or hung about its neck. When these preparations were complete, the body was carried to the tomb, accompanied by relatives, friends, and troops of hired mourners. All the Egyptian cemeteries lay upon the west side of

the Nile, and hence it was frequently necessary to cross the river. When this was the case, the coffin was embarked upon a richly adorned barge, and the funeral cortège followed in other boats. From the time of the Old Empire the sacred soil of Abydos was a favorite burial place, and bodies were brought thither for sepulture from all parts of Egypt. At the place of burial the officiating priests performed the appropriate ceremonies; extracts from the sacred books were read, incense was burned, offerings were made, and the body was then committed to the tomb. Every provision was made for the comfort of the deceased. Alabaster figures of fowls, and loaves of bread, and little wooden wine jars, were provided, which, by virtue of the charms repeated over them, acquired the properties of real food and drink. In the same way the food was supposed to be prepared in wooden models of kitchens by statuettes of cooks and bakers. Should the deceased wish for recreation, there were games of various kinds and his favorite papyri. Did he desire to travel, he might voyage in wooden models of boats which, with oars, rigging, and crew, were placed in the tomb. He was, moreover, spared the necessity of performing labor in the future life by numbers of statuettes called *ushabtiu*, or "answerers," which answered to his name and took his place whenever any work was assigned to him. The tombs of the Egyptians varied with the period and with the means of the deceased and his family. Under the Old Empire wealthy nobles built the so-called mastaba tombs, flat oblong structures of stone, which surround the pyramids of the kings of the Fourth and Fifth dynasties. From the end of the Old Empire grotto tombs, hewn out of the solid rock, were preferred. Such tombs contained several chambers, and their walls were usually adorned with sculptures and paintings. To each tomb was attached a funerary chapel, where offerings were made from time to time. Tombs of this kind were, of course, only within the reach of great nobles and wealthy officials. For persons of moderate means a common type of tomb, under the Middle and New empires, consisted of a small pyramid of brick standing upon a low square base and having a little portico in front to represent the funerary chapel. The great majority of the people were, however, buried in the ground, and the site of the grave was usually marked by a stele, on which was carved a representation of the deceased standing before a table of offerings in the presence of Osiris and other gods. The poor were buried in shallow graves, without a coffin and with no stele to mark the spot; but the small alabaster bowls and the bones of animals found in these graves show that even here the welfare of the deceased had not been neglected. Consult: Breasted, *A History of Egypt* (New York, 1905); Erman, *Life in Ancient Egypt* (London, 1894); Wiedemann, *Alt-Aegypten* (Stuttgart, 1891) and *Aegyptische Geschichte* (Gotha, 1884-88); Duemichen and Meyer, *Geschichte des alten Aegyptens* (Berlin, 1878-87). Wilkinson, *The Manners and Customs of the Ancient Egyptians* (ed. Birch, London, 1878), is antiquated, but is full of valuable illustrations.

HISTORY

Ancient History. All historical books written in hieroglyphics have been lost. Their ex-

istence is proved only by fragments of a short extract (a list of kings) on papyrus, preserved in Turin. (See TURIN PAPYRUS.) Manetho, a priest of Sebennytus, under Ptolemy Philadelphus, wrote an Egyptian history in three books, which has also been lost. Epitomes of it are preserved in the works of Josephus, Julius Africanus, Eusebius, and George Syncellus; but they are inconsistent and probably unreliable. Some historical material is found in Herodotus, Diodorus, and Eratosthenes, but it is intermingled with many errors. We are therefore compelled to rely chiefly on the inscriptions, which do not always supply adequate information. The greatest difficulty is in the matter of chronology. The Egyptians themselves had no fixed era, but dated by the regnal years of the respective kings, and the inscriptions alone do not always furnish a reliable connection between reigns. In the scanty extracts from Manetho's history the chronological figures have been largely corrupted. Therefore the different systems of modern scholars lack uniformity. For example, the dates assigned to the first historical reign, that of King Menes, vary as follows: 5702 (Boekh); 5613 (Unger); 5004 (Mariette); 4400 (Brugsch); 3892 (Lepsius); 3623 (Bunsen); 3400 (Breasted); 2000 B.C. (Sharpe); etc. At the present day scholars content themselves with fixing approximate or "minimal dates," showing before what year a king must have reigned, though he may have lived 100 or even 1000 years earlier. Up to the present time no date before the eighth century B.C. has been fixed with certainty, and a fairly close approximation is possible only up to about 1600 B.C. Manetho's division of all the rulers of Egypt from the earliest period down to 342 B.C. into 30, dynasties or groups (not strictly families) has been, in general, confirmed. Dynasties One to Six are called the Old Empire; Eleven to Fourteen, the Middle Empire; with dynasty Eighteen the New Empire begins.

Egypt was apparently a civilized state at as early a date as was Babylonia. The possibility cannot be denied that Egyptian civilization may have been derived from that ancient centre of culture, but the evidence is not sufficient to decide the question. At any rate, long before 3000 B.C., Egypt possessed an independent culture, at least as high as that of Babylonia. The earliest history is obscured. The later priests filled many thousands of years with the mythical reigns of the different gods, after which they placed 4000 or more years of the demigods, or *manes*, i.e., prehistoric kings, whose names had been lost. The Egyptians considered Menes, or *Meni*, from this as the first remarkable historical King. We now possess many objects which seem to date from his time, found chiefly in the two great royal tombs at Nagada and at Abydos, and possibly relies of a few earlier kings, who even at that time ruled over all Egypt. The time when Egypt was divided into two kingdoms, the Delta and the Southern Land, has not yet been traced by archaeology, although in the royal titles the remembrance of that prehistoric division of the "two countries" was preserved even down to Roman times. The large tombs of the kings of dynasties One and Two were situated near Abydos and This (whence Manetho calls them Thinitic kings); these tombs were examined imperfectly by Amélineau in 1896 and afterward

thoroughly by Petrie. (Consult his *Royal Tombs*, London, 1900 et seq.) Thus we can go back to the middle of the fourth millennium B.C. or earlier. Of dynasty Three we know little more than the names of the principal kings. They resided near Memphis, and their tombs gradually assumed the later, pyramidal form. The earliest example, the step pyramid near Saqqara, is the work of Zoser, the fifth King of this dynasty. Under him we find the copper mines near Mount Sinai already being worked by the Egyptians.

Dynasty Four has left a great mass of monuments. The first King, Snefru, was the first great warrior. He made expeditions into Nubia and Syria and opened a new copper mine at Wadi Magharah. His two successors, the Cheops (q.v.) and Chephren (q.v.) of Herodotus, built the two largest pyramids—works which were never equaled at any later period. Later tradition ascribes the famous Sphinx near the pyramids to Chephren, but this is doubtful. Menkaurê, or Mycerinus, built the third in size of the great pyramids; all subsequent royal pyramids are considerably smaller. Under this and the following dynasty Egyptian sculpture reached its acme of perfection (c. 2800 B.C.). The most remarkable monument of dynasty Five (12 kings) is the sun temple near Riga, of which a building in the form of an obelisk has remained. The last King, called Onnos by Manetho, inaugurated the custom of placing the chamber of the pyramid with . . . This example, followed regularly in dynasty Six, has furnished to us the extensive texts of the pyramids opened in 1880 (those of Teti or Atoti, Pepi or Apopi I, Merenrê, Pepi II, and Neferkarê) (Breasted, *Ancient Records of Egypt*, Chicago, 1907). These are all magical texts, of no historic but of great linguistic interest, being copies of books so ancient that they were partially unintelligible even to the scribes of that age. Pepi I (or perhaps Apopi—the vowels are not expressed) left numerous traces of his building activity; he also waged a great war in Palestine, for which he used many negro troops from the tributary regions of Nubia. Most of the kings of this period built their residences—every king building a new city—around Memphis; the city of Memphis itself derived its name (*Mennofer*, 'Good Abode') from that of the pyramid of Pepi I, which stood in the vicinity. Pepi II is reported to have reigned more than 90 years. Under his successor we hear of an expedition into the negro countries on the White Nile, to procure a pygmy for the King (c. 2500).

Dynasties Seven to Nine form a very obscure period which has left hardly any monuments. The princes of the nomes (counties) had become so independent that the power of the king decreased. Dynasties Seven and Eight were of Memphitic, Nine and Ten of Theban origin. The latter had to fight continually against rebellious nomarchs (counts), especially against those of Thebes, who began to claim the royal title and finally succeeded in conquering the whole country, ruling as dynasty Eleven. The last six kings of this family (nearly all called Antef or Mentuhotep) governed a reunited kingdom. Under them Thebes, formerly an insignificant town, first became the capital of Egypt. The last King of this dynasty, Sankh-ka-rê, has left the first report of an expedition to Punt. (See below.) The Twelfth

(Theban) dynasty seems, from recent discoveries, to have begun about 2000 B.C. This period of about 200 years (seven kings, Amenemhat I, Usertesen I, Amenemhat II, Usertesen II, Usertesen III, Amenemhat III, Amenemhat IV, and a Queen, Seknefrurê) was considered by the later Egyptians as the golden age, especially of literature, the poetical style of which formed the model for all succeeding periods. Of the numerous buildings of dynasty Twelve and its renowned art, comparatively little has survived. Amenemhat III (q.v.) was the King Moeris of Herodotus, who gained the Province of the Faiyum for his dike by a branch of the Nile flowing into that oasis. Of the so-called Labyrinth the largest of all Egyptian temples, built at this time near the pyramid of Amenemhat III in the neighborhood of Hawarah, only a few stones remain. It does not seem that the Twelfth dynasty possessed more of Asia than the copper mines near Mount Sinai, but Nubia was gradually conquered as far as the Second Cataract, where Usertesen II established his frontier by building two strong fortresses on both sides of the Nile. The gold mines of that country were explored by the Pharaohs. After dynasty Twelve Egypt fell back into the former anarchy and strife of nomarchs, and it is likely that more than 130 princes, fighting with their neighbors for the crown, did not fill more than about a century (dynasties Thirteen and Fourteen).

Somewhat before 1700 Egypt was suddenly conquered by a foreign nation, whose rulers Manetho calls Hyksos. The name probably means "Ruler of Countries." (Consult Breasted, *History of Egypt*, p. 217.) We know nothing about the origin of these foreigners (they are usually taken for Canaanites or Turanians, though both theories lack proof) except that they had first conquered Syria. They may have been Arabians and Phœnicians. In Egypt they soon became Egyptianized. They kept only the Delta under their direct administration, leaving Upper Egypt to tributary native princes. The viceroys of Thebes (dynasty Seventeen) finally threw off the yoke of the foreign sovereign Apophis. After a long struggle, during which the Theban Sekenenre III and his successor Kames died, Amasis I (Aahmes or Ahmose) put an end to the rule of the Hyksos by driving them to their capital and chief fortress, Avaris, on the northeastern frontier (c.1600). Pursuing them into Palestine, Amasis, the first ruler of dynasty Eighteen, began the period of conquests in Asia. His unlimited power (the dominion of the many nomarchs had been wiped out during the long Hyksos war) and his army, disciplined and trained in the war of independence, enabled him to conquer Palestine and Phœnicia. His son Amenophis (Amenhotep) I, dying after a brief reign, became the patron saint of the Theban necropolis. Thothmes (also called Dhutmose) I penetrated into Nubia beyond the Third Cataract and into Syria as far as the Euphrates. His son Thothmes II had to share his power with his energetic sister and wife Hatshepsu (Hatasu), who also kept his minor successor. Thothmes III (her nephew?), under her control for 22 years, in one of the finest buildings of Egypt, her temple at Deir el-bahri, is depicted, as the most remarkable event of her reign, the equipment of a

whole fleet to sail to the Abyssinian and Somali coast, called Punt (Phut in the Bible), in order to bring back gold, rare animals, and, above all, incense, together with some living incense trees to be planted at Thebes. Formerly only single ships had been sent to Punt.

After Thothmes III had come to power by Hatshepsu's death (c.1500), he showed himself the greatest conqueror among the Pharaohs. In at least 16 campaigns he conquered Palestine, Phœnicia, and Syria as far as the Lower Orontes and penetrated victoriously as far as northern Mesopotamia (Mitanni), storming Carchemish on the Euphrates and hunting elephants in that region. With his rich booty he embellished the temples of Egypt in a manner unequalled by any of his predecessors, though they had all been great builders. The gigantic temple of Ammon at Karnak is chiefly his work. His son Amenophis (Amenhotep) II (c.1480) maintained the Egyptian possessions in Asia, and so did Thothmes IV, but Amenophis II gradually lost the northern regions. He lived on good terms with Mitanni and married the sister of its King Dushrata. For an account of the cuneiform dispatches received from Asia during the reign of this King and that of his son, which were found near Tell el-Amarna, see AMARNA LETTERS.

His son, by the beautiful and influential Queen Teye, Amenophis IV (about 1410), caused a great revolution by trying to replace the old religion with a solar cult approaching monotheism. He persecuted the worship of the supreme god Ammon with special vehemence, carrying his animosity so far as to obliterate the name of the god from earlier monuments and to change his own name, which contained that of Ammon, to "The Splendor of the Sun" (Akhunaten). He removed his residence from Ammon's city, Thebes, and built a new capital at Tel el-Amarna, in Middle Egypt. After his death (about 1395) the new religion, which had previously met with great opposition, was destroyed together with its temples under the following pharaohs: Akhenaten, Smenkh-karê, Tutankhamôn and King Haremheb (about 1308) completed the restoration of the old creed.

With the short-lived Ramses I, dynasty Nineteen (about 1350) begins. Sethos (Sety, Seti, or Setoy) I, his successor, a great warrior, whose tomb in Biban el-Moluk is the finest of all the royal tombs there, attempted to win back the parts of Middle Syria which had been lost and was there entangled in a war with the Kheta or Hittites, whose kingdom seems to have had its original centre in Cappadocia. His son Ramses II, or Sesostris (c.1330 B.C.), continued this war for 20 years with varying success. Finally at the peace concluded with the Hittites and sealed by a marriage between Ramses and the daughter of their King, Syria was divided, and Egypt retained Palestine and the southern half of Phœnicia. The numerous representations of a few modest victories (chiefly that near Kadesh on the Orontes, later Laodicea and Libanum) made the Greeks believe that Ramses II had been the conqueror of half the world. However, his activity as a builder during his reign of 67 years was beyond comparison, though he usurped many monuments, replacing earlier names by his own. Perhaps two-thirds of all the monuments bear his cartouche. As he colonized Goshen (the modern Wadi Tumilat) and built there the cities of

Pithom and Rameses, he has been pointed out as the Pharaoh who oppressed the Israelites, and his son has been deemed the Pharaoh of the Exodus. But an inscription found in 1896 shows that, in the fifth year of his son Merneptah, Israel was already settled in Palestine, and that an earlier date must be sought for the Exodus. On the other hand, it is clear from the Amarna Letters (q.v.), written about 1400 B.C., that at that time Israel had not yet entered the Promised Land. The date of the Exodus must therefore be placed in the interval between these two extreme limits, or, in round numbers, between 1400 and 1250 B.C. The theory is sometimes advanced that the ancestors of Israel settled in Egypt under the Hyksos kings, but there is no evidence in support of this view. In fact, with the single exception of Merneptah's inscription, there is no mention of Israel in the Egyptian records, and nothing is known in regard to the date of the chosen people's settlement in Egypt or the length of their sojourn there. All theories upon this subject are based upon little more than pure conjecture. Under Merneptah the Libyans devastated the Western Delta, and pirates from Asia Minor and Europe (the Akaywash (Achaans?), the Shardin (Sardinians), and Lûk (Lycians). These enemies joined their forces and had almost reached Memphis when they were met by the Egyptian army and annihilated. Dynasty Nineteen ends in 1286, with three kings (of whom one is said to have been a Syrian usurper) and a queen.

Setnakht, the founder of dynasty Twenty, re-established order. His son Rameses III (c.1210 B.C.) repelled several invasions of the Libyans and defended Egypt and the Syrian provinces from the raids of the pirates mentioned above, as well as from barbarians coming by land from Asia Minor. A branch of the Philistines, settled in Palestine at that time, Rameses plundered the land of the Amorites north of Palestine. His palace and favorite temple were at Medinet Habu. The nine Ramesides after him reigned peacefully to about 1100, when the high priests of Thebes, who had become very rich, especially through the donations of Rameses III, took the crown. They had soon, however, to yield to a new dynasty

from Tanis. At that time the pharaoh gave up the task of protecting the royal tombs of dynasties Eighteen to Twenty against thieves and hid most of the royal mummies in a secret pit, where they were discovered in 1881. A few tombs, which a landslide had made inaccessible to thieves and police, were discovered intact in 1898.

The Libyan mercenaries had meantime become so powerful that dynasty Twenty-two (about 950) was founded by one of their generals, Shoshenk I (the Shishak of the Bible), who plundered Judaea and Israel under Jeroboam and Rehoboam. His successors were called Shoshenk (3), Usorkon (3), Takelot (2), and Pimay. Under dynasty Twenty-three (from Bubastus, about 800) the country again split up into many small kingdoms ruled by Libyan officers, and the way was thus left open for the attacks of the kings of Ethiopia (q.v.), who had been independent since dynasty Twenty-one. About 750 the Ethiopian Pankhy (or Piankhy) was prevented from subjugating all of Egypt by the resistance of Tefnakht, the ruler of Sais and

Memphis; but Pankhy's grandson Shabako succeeded in dethroning Tefnakht's son, the wise Bocchoris (Bok-en-renef), with whom dynasty Twenty-four came to an end (c.720?). The Ethiopians form dynasty Twenty-five. After Shabatako, Taharko (the Tirhaka of the Bible, c.700?) pursued a policy hostile to Esaraddon, King of Assyria, who attacked Egypt in 673 and conquered it in 670. The Assyrian monarch divided the country among 20 tributary princes, descendants of the old Libyan families. The Ethiopians twice again invaded Egypt in 667 under the new King Tan(u)t-amen, but unsuccessfully. The Assyrian vassal Psammetich, Prince of Sais, a descendant of dynasty Twenty-four, aided by Greek and Carian mercenaries, made himself independent master of the country (663), when Assyria's power declined. The new dynasty (Twenty-six) is remarkable for its revival of art with archaistic tendencies. Psammetich's son Nekao (Necho) II (609-594) slew Josiah of Judah and conquered Syria as far as the Euphrates; but he soon lost it to the new Babylonian Empire, being defeated by Nebuchadnezzar at Carchemish. Necho dug the first canal connecting the Nile, and thus the Mediterranean, with the Red Sea. He also built a fleet and sent Phœnician sailors around Africa. Apries (Uahabre, the Hophra of the Bible, 588-569), the successor of Psammetich II, vainly tried to prevent the destruction of Jerusalem by Nebuchadnezzar (586). Amosis II (Amasis, 569-526), in consequence of a military revolt, first took Upper Egypt and three years later slew Apries in battle. With diplomatic skill he maintained himself against the Babylonians, and later against the Persians; but his son Psammetich III closed this flourishing dynasty by a reign of only one year. In 525 Cambyses defeated him at Pelusium, and Egypt became a Persian province.

The revolts of the Libyan officers Khabbash (487), Inarus, and Amyrtæus (460-450), aided by the Athenians) were suppressed; but in 414 the Persians were expelled, and Egypt was free from their rule until 343. In the interval, however, the country was a prey to internal strifes. The Persian reconquest was followed by many cruelties; the last Egyptian King, Nectanebus, fled to Ethiopia. Alexander occupied Egypt in 332 and founded Alexandria in 331. On the death of Alexander (323 B.C.) one of his generals, Ptolemy, son of Lagos, became Macedonian Governor of Egypt. From the first he was virtually an independent ruler, though he did not assume the royal title till 306 B.C. He was a wise and politic sovereign, and under his reign Egypt became a power of the very first rank. He conciliated his native subjects by treating with respect their religion and by long-established customs of the country. Under Ptolemy and his successors Alexandria, the new capital of Egypt, increased rapidly in importance and soon became the foremost city of the world. Its commerce was far-reaching and brought vast wealth into the hands of its merchants. As a centre of literary culture, it was even more famous than as a centre of commerce. The celebrated museum and library founded by Ptolemy I exerted a profound influence and attracted to Alexandria men of letters and of science from all parts of the Hellenic world. Ptolemy I died in 284 B.C. His grandson Ptolemy III (247-222) waged a successful war with Syria and greatly extended

the foreign possessions of Egypt. After this there followed a period of steady decline. Antiochus the Great of Syria and Philip V of Macedon deprived Ptolemy V (205-181 B.C.) of his Syrian and Ægean possessions, and but for the intervention of Rome would have seized Egypt as well. Henceforth, although her commerce increased in importance, and Alexandria was still the great centre of literature and science, Egypt existed as an independent kingdom only by the sufferance of Rome and lost all external influence. Ptolemy XIII (80-52 B.C.) bequeathed his kingdom to his elder daughter Cleopatra (q.v.) and his elder son Ptolemy XIV. Cleopatra made herself sole ruler and finally terminated an adventurous career by suicide in 30 B.C. With her the kingdom of the Ptolemies came to an end, and Egypt became a Roman province.

Augustus made Egypt a Roman province under a governor of equestrian rank. It remained rather a quiet possession of the Romans. Many temples were erected under the Roman dominion. The invasion by the Ethiopians (24 B.C.) and that by Zenobia of Palmyra (270 A.D.) are the most important events of this period. The rapacious desert tribes of the Blemmyans were often troublesome. Christianity spread with special success among the Egyptians. Gnosticism and "heavenly" (on heathen models) had their origin here. Paganism was persecuted and forbidden in 391 A.D., being tolerated only on the island of Philæ until the reign of Justinian. Schismatic contests among the Christians did much harm.

Egypt After the Fall of Rome. After the fall of the Roman Empire Egypt almost disappeared from the knowledge of Europe, but it occupied an important place in the Mohammedan world. It was conquered by the Arabs under Amru (639-641 A.D.) and in 969 became the seat of power of the Fatimite dynasty, and its capital, Cairo, was one of the religious centres of Islam. The Ayubites succeeded the Fatimites and under Saladin (1171-93) united much of the Mohammedan world under their rule. In the thirteenth century it was politically and commercially the real heart of Mohammedanism, and the later Crusaders made it their objective point, with the idea of striking at the vital seat of the enemy's strength. The Crusaders took Damietta in 1219, but were caught in the Delta on the march to Cairo and forced to cede all their conquests (1220). Damietta was again captured in 1249, by Louis IX of France; but his army met a similar fate to that of the warriors of the Fifth Crusade in advancing on Cairo. In the retreat upon Damietta the army was destroyed, and the King was captured and compelled to pay a large ransom, a part of which was the surrender of Damietta. Under the Mameluke sultans (1250-1517), vigorous warriors but poor administrators, the country fell into poverty and anarchy. The Turkish conquest (1517) by Selim I left the power of the Mameluke chiefs nearly unchanged. In 1798 Napoleon Bonaparte invaded Egypt and defeated the Mamelukes near the pyramids; but the French forces in Egypt were expelled by the Turks, with British help, in 1801. In 1811 Mehemet Ali Pasha (q.v.) massacred the Mamelukes and formed an army which conquered parts of Arabia (1816) and Nubia (1820-22), but lost many troops in aiding the Porte during the Greek Revolution. Mehemet

Ali founded the present ruling dynasty and established himself as a practically independent ruler. In 1831 he rebelled, conquered Syria, and developed designs upon the whole Ottoman Empire; but in 1840 the intervention of Russia, England, Austria, and Prussia forced him to evacuate Syria and renew his allegiance to the Porte. He improved the agriculture and defense of the country, but nearly ruined the people by taxes and monopolies. He died in 1849, and his successors, his son Abbas Pasha (1849-54) and his son Ismail Pasha (1854-63), restored prosperity to the country and began the Suez Canal. Ismail Pasha (1863-79), who first received the title of Khedive or Viceroy from the Porte, promoted the construction of the Suez Canal by De Lesseps, extended the conquest of the Sudan begun by Mehemet Ali, but was forced by the Porte several times to reduce his army and navy. Upon his accession the Egyptian debt was \$16,000,000; in 1879 it had risen to \$500,000,000. English and French banking houses were largely concerned in the solvency of the Egyptian government, and in 1875 the Khedive sold his 176,602 shares in the Suez Canal for £4,000,000 to England, thus laying the foundation for that country's influence in Egypt. In 1876 the revenue was put under the management of European commissioners; in 1878 the Khedive's private property went to help the payment of the interest on the public debt. His reckless extravagance made the Egyptian question one of European politics, and it was closely associated with the Eastern question (q.v.) by the opening of the Suez Canal.

When Ismail, in 1879, dismissed his financial minister, Nubar Pasha, and refused the payment of interest, the European governments forced his abdication in favor of his son Tewfik (1879-92). In 1880 a dual British and French control was established, which caused a Nationalist revolt in the following year, headed by Arabi Pasha (q.v.), a colonel in the army. The demands of the revolutionists were that the army should be increased to normal strength, that the Prime Minister of the Khedive, Riaz Pasha, should be dismissed, and that a Chamber of Notables, or National Parliament, should be convened to assume the government of the people as a representative body. Tewfik was alarmed by the proportions which the revolt had assumed, and a Chamber of Notables was summoned, which met at Cairo before the end of the year. In 1882 Arabi was taken into the new Cabinet as Assistant Secretary of War. When it was found that France and England, through the Controller General, were inclined to resist all the demands of the Chamber that would limit foreign interference in the management of the finances, the resentment of the popular, or National, party rose to fever heat. Sherif Pasha, the new Premier, favored the European powers. He was therefore forced to resign, and a new ministry was appointed, with Mahmud Sami and Arabi Pasha at its head. But the Khedive and his ministry represented such opposite lines of policy that it was evident that a rupture between them was inevitable, and in the middle of May the crisis came. The Khedive's action in pardoning certain political offenders was violently attacked by the Nationalists, and England and France each sent out a fleet to Alexandria to maintain the authority of the Khedive, and demanded the resignation of the ministry and the exile of Arabi. The ministers obeyed,

but a popular outbreak caused the Khedive to reinstate Arabi. He was now the idol of the army and the populace, who, encouraged by their success, were threatening violence against their foreign oppressors. An ordinary street fight in Alexandria culminated in a general uprising of the native populace against the Europeans, June 11. Arabi was commissioned by the Khedive to restore order; but his known sympathy with the rioters only increased the panic of the foreign colony, which fled from the city. England and France had vainly urged the Sultan to send troops into Egypt to enforce the authority of the Khedive and to suppress the growing power of Arabi, who was virtually dictator of the country. The French hesitated to act. Great Britain in vain urged the Sultan to take a firm stand and, after inviting the coöperation of Italy, determined to take matters into her own hand. A *casus belli* was found in the fact that certain forts in the harbor of Alexandria were being armed by orders of Arabi. The English admiral, Sir Beauchamp Seymour, accordingly bombarded the town. On the next day (June 12) the insurgents evacuated Alexandria, leaving it in flames, and intrenched themselves at Kafi Dowar, about 12 miles distant. The Khedive sought refuge with the English fleet. He was formally deposed by the Nationalists, who organized a provisional government at Cairo and intrusted the defense of the country to Arabi. Meanwhile the English, after an ineffectual siege of some weeks, abandoned the attack on Kafi Dowar, and an Anglo-Indian army of 40,000 men was sent across the Isthmus of Suez, under command of Sir Garnet Wolseley. They landed at Ismailia and advanced to Tel el-Kebir, where a large army of insurgents had thrown up intrenchments. These were stormed September 13. A forced march was then made on Cairo, which was reached by nightfall. Arabi at once surrendered, the National army was disbanded, and the Khedive was restored to his authority. Arabi was sentenced to death, but the sentence was commuted to exile on the island of Ceylon.

Various reforms were introduced by the English, acting through Lord Dufferin, who was appointed Special Commissioner to Egypt. The French having taken no part either in suppressing rebellion or in the subsequent reorganization, the dual control came to an end in 1883, notwithstanding the protest of France. An army of occupation was deemed necessary for a while to preserve tranquillity, but it was promised that its size should be steadily reduced. This promise, owing to a serious outbreak of the Arabs in the Sudan (q.v.) and the inherent weakness of the khedival government, was not redeemed. Egypt became practically a dependency of England, garrisoned by English troops, and with a government whose policy is in all things directed by the representative of England, though still carried out in the name of the Khedive. The Suez Canal, the new gateway to the East, and the strategic position of Egypt with reference to the development and control of Africa, gave that country a new importance, especially for Great Britain. Egypt is still nominally a province of the Ottoman Empire; but the government of Great Britain, where half of the Egyptian national debt is held, undertook to represent the foreign creditors. The commander of the army, known as the sirdar, is an English officer. There is an In-

ternational Court, on which 13 European countries and the United States are represented, which has jurisdiction in cases in which foreigners are concerned. The Khedive and the government may be held responsible before his court. The finances are guarded by the International Debt Commission, on which all the Great Powers of Europe are represented. Under British control the expenditures have been brought within the receipts, taxes have been reduced, and compulsory labor and slavery have been abolished. The Sudan, subject to Egypt in some measure since 1820, with its fanatical tribes of fearless though barbaric warriors, was a problem for the administrators of Egypt to deal with; its control was of great strategic importance, and it was a center of the slave trade. In 1874 General Gordon (q.v.) was appointed Governor-General of the Sudan and succeeded in partially organizing the country and suppressing the slave trade. He was succeeded in 1881 by Raouf Pasha, under whom the country relapsed into barbarism. The advent of the Mahdi (q.v.), Mohammed Ahmet, in 1883, brought religious fanaticism into the struggle against Egyptian control. The rapid increase of the Mahdi power and the defeat of the Anglo-Egyptian army under Hicks Pasha led the government to send General Gordon back to the Sudan in 1884. He was soon cut off in Khartum, and the relief expedition under Wolseley arrived too late (Jan. 28, 1885) to save him. The Sudan was left to itself until 1894, when Sir Herbert Kitchener, in a series of campaigns which proved the quality of the new Egyptian army, succeeded in reestablishing the authority of the governments over the Egyptian Sudan, his final triumph being the battle of Omdurman (Sept. 2, 1898). The defeat and death of the Khalifa in the battle of Om Debrikat in 1899 and the capture of the last Mahdist leader, Osman Digna, in the following year hastened the pacification of the country. Tewfik's son, Abbas Hilmi, who had been educated in Europe, succeeded as Khedive, Jan. 7, 1892, and proved an able and enlightened ruler. Lord Cromer, the British Consul General, has had a predominant influence in shaping the course of affairs in Egypt. The economic rehabilitation of the country has proceeded rapidly, chief among the works of public utility undertaken being the great Aswan dam, completed in 1902. By the Agreement of April 8, 1904, between France and Great Britain, the former pledged itself to abstain from interference with British policy in Egypt by not insisting upon the definite settlement of the question of occupation. Since the opening of the twentieth century the all-important political question has been that of Egyptian Nationalism. The great Pan-Islamic upheaval which marked its first decade was particularly noticeable in Egypt. In 1906 a great Mohammedan petition was presented to the Prince of Wales, then in Cairo, beseeching independence. A nationalistic party was formed under the energetic leadership of Mustapha Kamel, and at the same time the Denshawai affair stirred up the feelings of the Egyptians to a high pitch, for an arbitrary court-martial controlled by English officers had acted in this instance with great and unnecessary harshness. Earl Cromer, the great English Viceroy, resigned and Sir Eldon Gorst took his place in 1907. A lull now occurred. Gorst inaugurated a few reforms, but it was quite evident that he had no intention of

giving up Great Britain's control. There were renewed outbreaks. The students of the University of Cairo went on strike; the nationalistic press grew rapidly; the Egyptian Prime Minister was assassinated. The government promptly enforced an old press-gag law, and Mr. Roosevelt, aroused by the scene from the Sudan, aroused the ire of Egyptian patriots by a pro-English speech. In 1911 Sir Eldon Gorst died, and his post was taken by Lord Kitchener, who took measures for the pacification of the country by economic reforms. A plot to assassinate Kitchener was unearthed in 1912.

EGYPT, PLAGUES OF. See PLAGUES OF EGYPT.

EGYPTIAN ART. The art of Egypt is naturally divided into three main divisions: that of ancient times; the early Christian period of Coptic and Byzantine art; and the Mohammedan period, from the Arab conquest in 642 to the present time. The third of these divisions is treated under the article MOHAMMEDAN ART (q.v.); this article deals with the first two.

The date of the beginnings of ancient Egyptian art is not known; the earliest-dated monuments are hardly as old as the oldest Babylonian remains. But these monuments confront us with the vestiges of a highly developed civilization whose origins must have been in a far more remote antiquity. The researches of Petrie and De Morgan have uncovered many early and archaic remains, but it is not certain that even those of the Stone age antedate the earliest historic monuments. It is customary to divide ancient Egyptian art history into five periods, measured by the dynasties of the list of Manetho (q.v.): the Ancient Empire from about 3500 to 2160 B.C., covering 10 dynasties; the Middle Empire (two dynasties, 2160-1788); after the Hyksos dominion of five dynasties, the New Empire (Eighteenth-Twentieth dynasty, 1588-1150); the Saite, or Decadent, period of the New Empire (1150-324); and the Ptolemaic Revival (Twenty-sixth-Thirtieth dynasty and Macedonian and Roman dominions, 324 B.C.-330 A.D.). The Christian art that follows, whether Coptic or Byzantine, is less Egyptian than cosmopolitan.

Architecture. The monuments of the Old Empire belong rather to engineering than to architecture, but, with all their simplicity, possess great material grandeur; they are almost wholly sepulchral, comprising pyramids, mastabas, or masonry tombs, and hypogea, or excavated tombs. The pyramids (see PYRAMID), over 100 in number, were erected for the burial of members of royal and noble families, and each one contains a burial chamber and a number of passages. The earliest-dated pyramid is the stepped structure at Saqqara, 190 feet high, in six steps, built of brick. There are similar structures at Abusir and Meidum. These imply possibly a knowledge on the part of the Egyptians of the stepped temple pyramids of Babylonia, also of brick. But stone soon came to be the material used for the Egyptian pyramids. This is illustrated by the three famous examples at Ghizeh, all belonging to kings of the Fourth dynasty, Khufu (Cheops), Chephrer, and Menkaura, that of the first named the greatest of all, being 482 feet high on a base 780 feet square. For persons of royal rank a tomb took the form of a pyramid (see MASTABA). The best-preserved shrine of this period is the so-called temple of the Sphinx (q.v.), of extremely primitive architecture, consisting of a hall in the form of a T, roofed with plain stone lintels on 16 perfectly plain square stone piers. Remains of a few other temples have been found, all associated with sepulchres. During this first period there is little architectural memberment or decoration. No style has yet been formed. The Middle Empire shows a considerable change: columns appear with polygonal or fluted shafts; others of quatrefoil or clustered section, with simple capitals. The careful execution that had before been confined to the industrial arts was applied to the decoration of buildings: color and relief sculpture embellished architecture. The rock-cut and free-

EGYPTIAN ARCHITECTURE
TEMPLE AT PHILÆ

standing tombs gave a chance to design façades, porticoes, and columnar interiors. At Abydos is the group of tombs historically most interesting, as this was from the beginning of Egyptian history the most sacred burial place. Here the usual type is free-standing. Of rock-cut tombs the most famous group is at Beni Hassan.

But the peculiar merit of this period is the origination of the grand type of *temple architecture* which was followed throughout the rest of Egyptian history. In these the column, lintel, and wall of cut stone carefully fitted and laid and secured by cramps and dowels, present the earliest examples of monumental architecture in stone. The type of this period is represented by only a few examples in ruins at Bubastis, Karnak, etc.; it received its full development after the expulsion of the Hyksos kings, under the New Empire. Aside from a few exceptions, such as the temple of Amenophis III at Elephantine, with its peristyle surrounding a cella, this type is the following: A road bordered by colossal sphinxes leads to the high-walled inclosure which hides the temple. The single imposing gateway is flanked by two tower-like pylons of very massive proportions;

grouping on the island of Philæ is the most picturesque in Egypt. Other important temples are that of Luxor, the Ramesseum, and those at Medinet-Abu, Edfu, Denderah, etc. Edfu is the most symmetrical and well preserved, but the group at Karnak is the most monumental and artistic in Egypt, the work of many monarchs of the Middle and New empires. Its hypostyle hall, measuring 170 × 340 feet, had a central nave with 12 of the highest columns ever used in Egypt, and aisles formed of 122 columns in nine rows. The capitals of the central aisle were bell-shaped; those of the side aisles were of the lotus-bud type. The temples of Philæ, Edfu, and Denderah are of the Ptolemaic period, during which the only marked changes from the style of the New Empire were the introduction of a screen wall between the front columns of the hypostyle hall, and a greater variety in the capitals, complex floral forms being especially favored. During the entire New Empire and Ptolemaic period architectural forms remained almost unchanged, except as above stated. Walls were built with a batter or slope, and surmounted by the unvarying Egyptian cornice, a huge flaring cavetto above a roll mold-

RESTORED FRONT OF AN EGYPTIAN TEMPLE WITH PYLONS AND GATEWAY.

through it an open court is reached, surrounded by one or even two rows of columns, making it resemble an atrium. From this court the foremost part of the sanctuary proper is reached, the hypostyle hall, divided into aisles by rows of columns, and lighted from above or from between the front columns. Finally comes the inner sanctuary with an isolated shrine in a dark columnar hall, surrounded by small chapels. The effectiveness of this arrangement, with its gradual transition from the brilliant sunlight of the court to the intense gloom of the farthest chapel, is increased by an upward slant or stepping of the floor level and the diminishing height and size of the successive parts. This simple scheme was usually complicated by additions made by succeeding monarchs in any great shrine like Karnak or Philæ; court after court, each with its entrance pylons, were strung together or connected by avenues, and independent sanctuaries were placed side by side. The

ing recalling a bundle of reeds. Columns were of various forms; the shafts, either circular or clustered in section, tapered slightly from the base upward and bore capitals of various types. Of these the chief were the inverted bell, the bud (single or clustered), the palm, and the Hathor-headed (four masks of Hathor supporting a shrine-shaped block). The upper part of the shaft had a necking of several bands. No other moldings, no other cornice, no other details appear. On the other hand, the surface decoration was wonderfully full and varied. The columns were covered with designs, and so was every inch of the walls. The favorite form was that of extremely low relief or incised sculpture, brilliantly colored, and arranged in systematic series of panoramic pictures, according to an elaborate mythological or historic system.

It was the great kings of the New Empire, the Thothmes, Amenhoteps, Setis, and Rameses, the conquerors of the East, who were the great-

est builders; and after them no revival comes until the Ptolemaic age. There were two classes of temples of different type, many of them associated with royal tombs. One series is that of the rock-cut temples with sculptured façades, of which the most famous are at Abu Simbel (q.v.), the work of Rameses II, their façades decorated with colossal statues, and their halls an imitation of the free-standing temples. Then come the royal tombs of the New Empire, dug deep into the mountain, as at Bab-el-Moluk, and the corresponding sepulchral temples. Of these the greatest is that of Queen Hatsue at Deir-el-Bahari, uniquely picturesque and new in type, partly excavated and partly built. Others approach more the usual type, as the Ramesseum, not far from it, and the Temple of Rameses III at Medinet Habu.

There are many remains of Egyptian civil and military architecture. At Thebes, Memphis, Bubastis, and many other cities, whole quarters remain; and the fortresses of Abydos, El-Kab, and Semneh, though of early date, are in excellent preservation, as are also the fortified walls of many cities, such as San, Saïs, and Thebes. The New Empire adopted the Asiatic type of fortifications with which its wars had familiarized it, and substituted stone for brick. In all private houses of any size the inner court and the flat roof were prominent features. The largest were hidden away in a garden or park, surrounded by high walls, and, besides the main residence, had many subordinate buildings, often as complete as those of a mediæval monastery.

Sculpture. While it seems probable that Babylonian architecture matured earlier than that of Egypt, it was quite the reverse with sculpture. The religious beliefs of the Egyptians led their early artists carefully to observe and copy the human figure in order to reproduce accurately each individual after death, so that the spirit and shade, the *ba* and the *ka*, should recognize their earthly tenement and be reunited to it. The sculptors were extremely prolific. The greatest collection is, of course, in the museum at Ghizeh; others of first importance are those of the Louvre, the British Museum, the Vatican, Florence, Turin, The Hague, and Berlin. A large proportion, however, of the works remain *in situ*, in the temples and tombs, both colossal statuary and series of reliefs, especially in the temples of Abydos, Edfu, Ipsambul, Philæ, and Thebes, and in the tombs at and near Beni Hassan, Memphis, and Thebes.

All the sculptures of the Old Empire have been found in tombs and have some funerary connection or significance. They are far more realistic than later works, and often have considerable value as portraits. The colossal and official style does not arise until the Middle Empire in connection with temple architecture, reaching its climax under the Rameses and Setis of the New Empire. From the plastic art was used to illustrate the life of the people. Each tomb contained a faithful detailed representation of the possessions, occupations, person, and family of the deceased, as well as scenes of his future life. In the inner chamber were several statues as he or she appeared in life; in the chamber of offerings were other statues, the table of offerings, and especially a series of scenes in low relief, usually colored quite brilliantly on a stucco ground, not shaded, but laid on in broad masses and with strong contrasts. In the New Empire two other forms

besides the low relief became popular—sunken relief (*cavo-relievo*) and outline relief (*staccato*)—with the result of making sculpture even more pictorial in effect. There was never much work done in high relief, and that was nearly all during the Old Empire. The methods of quarrying, transporting, blocking out, carving, finishing, and polishing sculptures, whether in relief or in the round, are among the scenes represented. The Greek tradition of the use of wood by Egyptian sculptors in the earliest times is borne out by the discovery of a number of wooden statues of the Old Empire, chief of which is the famous standing figure of an official nicknamed the *Sheik-el-beled* (Ghizeh Museum). Acacia and sycamore were among the woods used; apparently a sacred significance was attached to this material, as, later, among the Greeks. Basalt, diorite, and red granite were the favorite stones for statuary, while reliefs were mostly in softer varieties, as limestone and sandstone. At a late period red porphyry became popular. The element of color seems to have been considered necessary in sculpture; when it was not given by the stone itself—as in basalt, diorite, and red granite—it was obtained by stuccoing and painting the softer stones, and even wood. The methods of representation were purely conventional, and for the purpose of conveying an idea, not of producing an illusion (except in the case of the portrait statues of deceased persons). The main attempt was to show as much as possible to the beholder. Therefore in relief, figures were spread out as on a map, the head in profile (but the eye in front view), the shoulders full front, the arms and hands in profile, the trunk three-quarters, the legs and feet in profile. In scenes where several planes of figures are given, there is no attempt at perspective, but the rows are raised one above the other toward the background. In a garden the plants and trees are stacked horizontally on both sides; around a pond, on all four sides. In such cases nothing stands upright. Egyptian sculptors, undaunted by inability to reproduce scenes realistically, were prodigal with details. This inability does not become apparent in the simpler processional or other scenes, where only one plane is required, as in most Assyrian and all Greek reliefs. In such details the execution is surprisingly delicate and highly finished.

From the beginning there seem to have been two styles in sculpture, the hieratic-religious and the secular. The former was stiff, traditional, and with few types; the latter was easier, freer, and with much greater variety. The famous colossal statue of King Chephren, with hands on knees, in the familiar traditional attitude, shows also the type of slender body used for gods and kings, in contrast to the heavy, squat type—like that of the Coptic fellah—used for portraits of common folk, such as the above-mentioned *Sheik-el-beled*. Outside of any class, and the earliest large work of sculpture, is the colossal Sphinx of Ghizeh, which is now disintegrating under the changed climate. The favorite theme of the naturalistic portrait is perhaps the seated group of husband and wife, a theme in which truth to nature lasts even through the Middle Empire, as shown, for instance, in the group of Ra-Hotep and Nefert, of the Thirteenth dynasty, where the husband is of the negroid type so common before the New Empire. Outside of Egypt, the

EGYPTIAN ART
COLOSSAL STATUE OF RAMESES II., FOUND NEAR MEMPHIS

Florence Museum is particularly rich in these family groups. There are a few cases of *genre* and other scenes which are also particularly naturalistic, such as the "Royal Scribe," at the Louvre, and the "Girl on Her Knees Washing Clothes." The representations of divinities are very material, without being natural. They were usually of a composite human-animal type, reminiscent of totemism and fetishism: Sekhet-Bast, a lion or cat; Anubis, a jackal; Horus, a hawk; Chnum, a ram; Thoth, an ibis; Lebek, a crocodile. Usually the method was to place an animal's head on a human body, though sometimes the god was wholly human and accompanied by his animal emblem. Figures of the gods were multiplied innumerable on a small scale. The gods of Upper and of Lower Egypt were worshiped on the opposite walls of a temple, and the god's image, receiving the worship of the King, was repeated many hundreds of times in relief on the walls and columns, and even on the surfaces of the outer pylons. This was especially the case in later art. Small images of the gods in earthenware, and diorite were the million as objects of devotion, according to uniform types. The next class is that of official political art. Here also there is a traditional element. The scene of the colossal King, at whose feet cower a group of captives whom he is about to slaughter, is repeated without variation during many reigns. So is the scene of the victorious King in his chariot overturning his enemies, as sung of Rameses II in the famous poem of Pentaur. But even this political art had its realistic and free side. At Karnak the low reliefs, the captives defiling with their splendid and rich series of types of the different races and tribes inhabiting Syria, Phœnicia, and Palestine, the artists having succeeded in conveying racial traits with very few touches. In the same way the processional reliefs of Queen Hatasu at Deir-el-Bahari are very illustrative of the products and races of the South. But of even more varied interest are the reliefs and paintings in the tombs of private persons. In one of the tombs of the Middle Empire a scene represents the burial of a tribe in patriarchal fashion, in all its details, showing how traveling was done in the age of Moses. There was a distinct phase of naturalistic revival under Amenophis IV (Akhunaten) in the New Empire; otherwise the change was toward the stiff, the colossal, and the highly finished. Under the late Saitic dynasty there was a revival in the reign of Psammetichus, with a recurrence to the grace and delicacy of the time of Seti I and Rameses II. Then, when Greek art was introduced under the Ptolemies, sculpture was more affected than architecture.

Painting and Minor Arts. Painting in Egypt can hardly be called an independent art. It was largely an adjunct to sculpture and architecture, making of all Egyptian art a mass of color. In the tombs, however, especially during the Fifth and Sixth, the Eleventh, Twelfth, and Thirteenth dynasties, wall paintings were as popular as reliefs, had the same characteristics, and portrayed the same themes. The minor arts always flourished. They may, in fact, be said to have been the earliest to develop. Egyptian gold and enamel jewelry, with its rich necklaces and pectorals, illustrates an art of which the earliest examples date

back to the Fourth or Third dynasty. The Egyptians applied artistic design and decoration very successfully to articles of furniture, ornament, and domestic use—to chairs, beds, mirrors, boxes, spoons, etc.—and their artisans used wood, ivory, and the various metals with almost equal ease. These works were distributed throughout the Mediterranean basin by Phœnicians and Greeks, and so influenced the general history of design even more than the more monumental works.

Coptic Art. The place of early Christian art which developed in Egypt previous to the Arab conquest is interesting rather than important. The churches, of modified basilican type, are small, and more interesting for their details and as including some of the earliest vaulted churches known, than for any great architectural beauty. The oldest monasteries are those of the Copts, and those of the sixth and seventh centuries display a strong Byzantine influence in their carved ornament. Possibly the lattice screens in Coptic churches were the parents of the rich screens of the Arabic houses of Cairo. The Coptic textiles were often of great beauty, both of color and pattern. It is known that Coptic architects were employed by the Arab conquerors, as in the great mosque of Ibn Touloun.

Bibliography. Consult: Maspero, *Manual of Egyptian Archaeology* (revised ed., New York, 1913); Petrie, *History of Egypt*, 3 vols. (London, 1899-1905); Breasted, *A History of Egypt from the Earliest Time to the Persian Conquest* (New York, 1905). The fullest history is Perrot and Chipiez, *Histoire de l'art dans l'antiquité*, vol. i *Égypte* (Paris, 1882), trans. by Armstrong (London, 1883). Large series of monuments are published in such illustrated works as Prisse d'Avennes, *Histoire de l'art égyptien* (Paris, 1878-79); Lepsius, *Denkmäler aus Aegypten und Aethiopien* (Berlin, 1849-59). The relation of the plastic and minor arts to life is well given in Wilkinson, *The Manners and Customs of the Ancient Egyptians* (London, 1837-41). Capart, *Primitive Art in Egypt* (Paris, 1905), is a discussion of the early art of Egypt. The monumental work of Jomard, *Description de l'Égypte* (Paris, 1812-), is still of value, though superseded by later investigations. For Coptic art consult A. J. Butler, *The Ancient Coptic Churches of Egypt* (Oxford, 1884). The finest monographs on a large scale are those published by the Egyptian Exploration Fund and the Mission Archéologique Française du Caire. EGYPTIAN EXPLORATION FUND. A foundation promoted in 1882 by the Egyptologist Amelia R. Edwards (q.v.), for the excavation and study of Egyptian remains. Under its auspices Edouard Naville unearthed Goshen and the Temple of Bubastis; W. M. F. Petrie disclosed Naucratis and discovered fragments of the works of Euripides, Plato, and other writers; and E. A. Gardner made important finds of

pottery. An American branch was founded in 1883 by W. C. Winslow (q.v.), which rendered invaluable service in the prosecution of the work.

EGYPTIAN MUSIC. Except for abundant monumental evidence the information which we possess about Egyptian music is extremely meagre. It is derived either from inadequate accounts of ancient Greek authors, or from illustrations and specimens of their musical instruments. We do, however, know that music, crude and imperfect as their form of it was, has played an important rôle from before the time of the Old Empire down to the songs of the Nile boatmen of to-day. They sang odes to the gods, songs in praise of their heroes, dirges to the dead, and their entertainments were considered incomplete without musicians and dancers. From the fact that Jewish and Assyrian musical instruments were, for the most part, of the same character as the Egyptian it is not unfair perhaps to assume that the music of Egypt was also much like that of the neighboring civilized countries.

Probably, as in the case of every nation which has developed from barbarism to civilization, the first music was merely an accompaniment to the dance. Some of the earliest representations show hands in rhythm to music, and this method of marking time is used at the present day. During the Old Empire the dances were generally slow and dignified, and the accompaniment was that of voices; but with the beginning of the New Empire the tempo of the dances became rapid and the usual accompaniment was supplied by tambourines and castanets. The pirouette was a favorite dance, and in that, as in all their complicated figures, the use and position of the hands and the arms were of prime importance. The number of performers varied from 1 or 2 to 10 or 15; though, as the dramatic ballet was unknown, their more elaborate dances consisted rather of a number of small groups than of one integral whole.

Vocal music consisted of solos and choruses, which seem to have been entirely in unison. Women often sang without instrumental accompaniments, but the Egyptians seem to have felt that the voices of men needed the support of instruments. Many of the very ancient songs have been preserved in papyrus scrolls, and though they are inferior to those of the Greeks, they are remarkable for striking metaphors and naturalness of expression. Most famous, and one of the oldest of the songs, is that of the oxen treading out the corn. Various theories were formerly advanced to show that the Greeks derived their knowledge of music from the Egyptians; but though the latter had treatises on music, they seem to have had no system of notation and no definite ideas of harmony. Indeed, it is without parallel that a people so advanced in other arts as were the Egyptians should have had so little exact knowledge of the science of music. We have no definite information about their scales, though the seven-stringed lyre seems to have been tuned in conjoined tetrachords.

From the monuments we learn that the chief instruments of the Egyptians were the harp, lyre, single and double flute, lute, trumpet, sistrum, drum, tambourine, cymbals, and castanets.

Long before the lyre was known to the Greeks the Egyptians had both harps and lyres. The harp was their earliest instrument, and we have records of it before 3000 B.C. In its original form it had five or seven strings, and was extremely long (certainly over 6 feet), with a semicircular body. As it was developed, however, the number of strings was increased to 11 or 12, and, by 1300 B.C., to 22, while its size was greatly reduced. The strings (as on all Egyptian stringed instruments) were of catgut and were at the top wound around pegs which passed through the frame. At no time, however, did the Egyptians have pedals, or even, as in the Welsh harps, a double set of strings; consequently, unless retuned, they could be played but in one key. The ornamentation of harps was most elaborate, the heads and bodies being exquisitely carved and painted. Although the harp always remained a national instrument, its popularity was eclipsed later by the lyre, the form of which had from 6 to 20 strings and was considerably larger than its Grecian derivative. At a very early time flutes were in use. The long flute was held in a slanting position, and the short flute in a horizontal position. The number of apertures varied from three to five. Considerably later the double flute superseded the other two. It was played with both hands, one tube giving the melody while the other droned a monotone accompaniment.

By 400 or 500 B.C., in addition to the various forms of harp, lyre, and double flute, there were the *te-bouni* (a sort of banjo), the shoulder harp, and several kinds of drums. The *te-bouni* had a long neck and a cylindrical body over which parchment was stretched. It sometimes had two or three strings, but generally only one, and in subsequent centuries the monochord (q.v.) was developed from it. The shoulder harp was a link between the harp and guitar. A specimen preserved in the British Museum has a neck 22 inches long, a body 19 inches long and 4 inches wide, and 4 strings. As its name implies, it is played when resting on the shoulder. There were two common forms of drums, the larger one being a barrel-shaped instrument about 3 feet long and the smaller a cone-shaped earthenware vessel over the open end of which parchment was stretched. Still later were added the *sistrum*, a sort of rattle; and the *trigonon*, a triangularly shaped stringed instrument; the *tamboura*, a form of lute, sometimes provided with frets, and played with a plectrum; and the tambourine. Besides the principal instruments already enumerated, there were at different times numbers of derived instruments, varying slightly in form from their prototypes. The musical instruments used in war were trumpets, cymbals, and drums. In earliest times the musicians were generally men, but later women took their places, although there were always certain instruments which seem to have been the particular property of each sex. The particular music and the dance were Athor, Isis, and Aphrodite, and Bes, the dwarf god.

The modern musical instruments of the Egyptians are practically those of the Arabians. (See ARABIAN MUSIC.) The study of music is not pursued, but that there is a natural love of it is shown by the songs of the country folk, laborers, and boatmen at their work. The Nile sailors are particularly famous for

their songs, of which there is a considerable variety, many of them having been handed down from generation to generation for centuries.

For a general sketch of Egyptian music, consult: Mathews, *A Popular History of the Art of Music* (Chicago, 1894); H. Smith, *The World's Earliest Music* (London, 1904), pp. 25-62; and Goddard, *The Rise of Music* (ib., 1907), pp. 11-38; for more elaborate treatises, Engel, *Music of the Ancients* (ib., 1864); Wilkinson, *The Ancient Egyptians*, vol. i. (ib., 1879); and for examples of modern Egyptian songs, MacGregor, *Eastern Music* (ib., n. d.).

EGYPTOLOGY. The study of the language, history, and antiquities of ancient Egypt. As early as the sixteenth century the monuments of Egypt began to attract the attention of European scholars, and between 1529 and 1589 some ineffectual attempts were made to decipher the Egyptian hieroglyphics. In the following century the subject was revived by the learned Jesuit, Father Athanasius Kircher, one of the foremost scholars of his time, whose astonishing activity and versatility were exhibited in many fields of research. Kircher proceeded upon the mistaken theory that the hieroglyphic writing was a sort of symbolism for conveying abstruse religious mysteries, the individual characters being purely ideographic symbols. His efforts were therefore not more successful than those of his predecessors, and his fantastic renderings of hieroglyphic texts are among the most remarkable of Oriental literature. But though he failed in his main object, his works did much to excite an interest in Egyptian antiquities, and he also rendered valuable service by introducing the study of Coptic into Europe. His Coptic grammar, entitled *Lingua Aegyptiaca Restituta* (Rome, 1643-44), was the first published by a European scholar and for a long time formed the basis of all work done in this field. Kircher was followed by Lacroze, Wilkens, Mémoires, Quatremère, Zoëga, Jablonski, and many others who did much to develop the study of Coptic and of Egyptian antiquities and thus prepared the way for further progress. Down to the end of the eighteenth century hardly any progress was made in the decipherment of the hieroglyphics. Kircher's theory was, however, gradually discredited, and the belief gained ground that the hieroglyphic inscriptions were composed in the language actually spoken by the ancient Egyptians, and that they dealt with history, science, art, and other subjects of a more material character than religious mysteries. Professor Tychoen (1734-1815), of Rostock, was led by careful analysis of many texts to the correct conclusion that certain characters served merely to determine the meaning of words (see **HIEROGLYPHICS**); and the learned Coptic scholar Zoëga (1755-1809) was the first to point out that some of the characters at least

had purely phonetic values, and that the groups of signs inclosed in oval rings must represent the names of kings. This, however, was practically all that was known in regard to the subject, and many fanciful theories still prevailed. The means of solving the riddle was at length furnished by the famous Rosetta stone (q.v.), discovered in 1799, which contains a decree of the Egyptian priests in favor of Ptolemy V Epiphanes (205-181 B.C.), composed in Greek, with two parallel versions—one in the vernacular, written in the Demotic character, and the other in the classical language of ancient Egypt, written in hieroglyphics. The upper part of the hieroglyphic text was broken away, only the last 14 lines remaining; while the Greek and Demotic texts were nearly complete, and for this reason the Demotic portion was selected for the first attempts at decipherment. The French Orientalist, Baron Sylvestre de Sacy (1758-1838), by careful comparison of the Greek and Demotic texts, was able to distinguish in the latter several of the proper names occurring in the decree, and in his *Lettre au Citoyen Champollion sur l'inscription égyptienne du monument trouvé à Rosetta* (Paris, 1802) pointed out the Demotic groups corresponding to the names of Ptolemy, Berenice, and Alexander. This achievement was, however, surpassed by the Swedish scholar J. D. Akerbald (1763-1819), who established the phonetic values of nearly all the Demotic characters, and also by the Englishman, Dr. Thomas Young (1773-1829), who, by comparing the meaning of several words of the text. His results were published in his *Lettre sur l'inscription égyptienne de Rosette adressée au Citoyen S. de Sacy* (Paris, 1802). Following these investigators, the Englishman, Dr. Thomas Young (1773-1829) was a more careful study of many Egyptian inscriptions and papyrus rolls to distinguish between the Hieratic and the Demotic scripts and to determine the meaning of a number of groups of characters, although ignorant of their phonetic values. Utilizing Zoëga's conjecture that the groups of signs in oval rings were royal names, Young next pointed out the hieroglyphics equivalent for the name of Ptolemy in the Rosetta text and attempted to analyze it. The name is written with seven alphabetical characters (P t o l m i s), and three of them (P, t, and i) Young determined correctly. Of the remaining four he took the letter o for a silent determinative, and explained the letters l, m, and s as syllabic signs, reading them as *ole*, *ma*, and *os* respectively. He also recognized the name Berenice in a hieroglyphic inscription from Karnak, but in it he correctly determined but one additional character, the letter n. In his attempts to decipher other hieroglyphic names he was completely unsuccessful, and thus the sum of his achievements in hieroglyphic decipherment was the determination of four alphabetical characters. While to Young belongs the credit of being the first to assign correct phonetic values to a few hieroglyphic signs, the true credit for the decipherment of the Egyptian hieroglyphics and for the foundation of modern Egyptology belongs to Jean François Champollion (q.v.). Born at Grenoble in 1790, he early applied himself to the study of Egyptian antiquities, was a master of Coptic, and at the age of 24 was known as the author of an important work on the history and civil-

zation of ancient Egypt—*L'Égypte sous les Pharaons* (2 vols., Paris, 1811-14). In his investigations of the hieroglyphics Champollion, unlike Young, worked upon the theory that the characters used for writing royal proper names were purely alphabetic. On a small obelisk from Philæ, containing parallel hieroglyphic and Greek inscriptions, he read and correctly analyzed the names of Ptolemy and Cleopatra, and by phonetic values thus obtained of other hieroglyphically written names, he was able at once to control his results and to extend his system. In this way he was soon able to make out all the alphabetic characters and to read the names, not only of Ptolemaic kings and of Roman emperors, but also of the Pharaohs of the Old Empire. In the course of subsequent investigations he discovered the use of the ideograms and determinatives and surmised at least the phonetic employment of the syllabic signs. He published an outline of his system in his celebrated *Lettres à M. Dacier relatives à l'alphabet des hiéroglyphes phonétiques employé par les Égyptiens* (Paris, 1822), and developed it more fully in his *Précis du système hiéroglyphique des anciens Égyptiens* (ib., 1824; 2d ed., 1827-28). Until his death Champollion devoted himself with wonderful energy and success to the elucidation of the language, history, religion, and antiquities of ancient Egypt and left, in addition to his published works, a large mass of manuscript. His *Grammaire égyptienne* (ib., 1836-41) and his *Dictionnaire égyptien* (ib., 1841-46) were not published until after his death.

Champollion's results were not received without reserve. Among the chief opponents of his system were Spohn and Seyffarth, both professors at Leipzig. Seyffarth, who developed the system of Spohn, held the erroneous theory that the hieroglyphic characters were, with scarcely any exception, purely phonetic, and he even read the determinatives (see **HIEROGLYPHICS**) as separate words. His system thus formed the opposite extreme to that of Kircher, and his translations are almost as fantastic as those of his seventeenth-century predecessor. Seyffarth did much to retard the progress of Egyptology, but his system was finally discarded.

Of a very different character was the work of the distinguished German scholar Karl Richard Lepsius (q.v.). In his *Lettre à M. Rosellini sur l'alphabet hiéroglyphique* (Rome, 1837), Lepsius submitted Champollion's system to a searching criticism, and, while clearly proving its general correctness, he indicated a number of points in which revision was necessary. From 1842 to 1845 he headed the archaeological expedition sent out by King Frederick William of Prussia to explore Egypt and Nubia. The results of the expedition were published under Lepsius' editorial supervision in the magnificent *Denkmäler aus Aegypten und Aethiopien* (6 vols., Berlin, 1849-58), which contains careful drawings and architectural plans of all the principal monuments of Egypt accessible at that time as well as a remarkably extensive collection of inscriptions dating from all periods of Egyptian history. This great work is one of the chief monuments of modern Egyptology. In 1866 Lepsius had the good fortune to find at Tanis the celebrated *Decree of Canopus*, issued by the Egyptian priests in favor of Ptolemy III Euergetes and dating from the year 238 B.C.

The inscription is trilingual, and the Greek, Demotic, and hieroglyphic portions are all in an excellent state of preservation. A duplicate of it, found at Damanhûr in 1881, was published by Pierret under the title *Le décret trilingue de Canope* (Paris, 1881).

The first Egyptologist who really translated complete texts was the French academicien Vicomte Emmanuel de Rougé (died 1872). Applying strict philological methods, he pointed out, in his *Mémoire sur l'inscription d'Akmes* (Paris, 1851), in his *Etude sur une stèle égyptienne de la bibliothèque impériale* (ib., 1856-59), and in other works, the manner in which Egyptian texts should be interpreted and explained, and his *Chrestomathie égyptienne* (ib., 1867-76) completely revolutionized the treatment of Egyptian grammar. In the explanation of hieratic texts, hitherto much neglected, he was also successful, and in 1856 he read before the Institute of France a translation of nearly the whole of the poem celebrating the exploits of Rameses II in his war with the Hittites. In this special department of Egyptology he was, however, surpassed by his compatriot François Joseph Chavass, whose *Le papyrus magique Harris* (Châlons-sur-Saône, 1860) and *Voyage d'un égyptien en Syrie, en Phénicie, en Palestine*, etc. (Paris, 1866)—the latter published in collaboration with the English Egyptologist W. Goodwin—may be said to have laid the study of hieratic texts upon solid grounds.

The study of Demotic texts, neglected after the death of Champollion, was revived by Heinrich Brugsch (q.v.), whose *Grammaire démotique* (Paris, 1855) formed the basis of subsequent work in the field. In more recent years Eugène Revillout (*Chrestomathie démotique*, ib., 1870-80; *Nouvelle Chrestomathie démotique*, ib., 1878) and J. J. Hess (*Der demotische Roman von Sene Harnus*, Leipzig, 1888; *Der gnostische Papyrus von London*, Freiburg, 1892) deserve mention as specialists in Demotic. Among the many important works of Brugsch, however, the chief place must be assigned to his *Hieroglyphisch-demotisches Wörterbuch* (7 vols., Leipzig, 1867-82). The influence of this great thesaurus of the language upon the development of Egyptian grammar has been important. *Vocabulaire* is merely an abridgment of Brugsch's great work. Levi's *Vocabolario geroglifico-copto-ebraico* (Turin, 1887-89) has contributed little to the advancement of Egyptian grammar. A new and comprehensive Egyptian grammar was in 1902 in course of preparation in Germany, under the direction of Prof. Adolf Erman, of Berlin, but he did not expect that it would be ready for the press for several years. Professor Erman has the distinction of having inaugurated the historical method in the study of Egyptian grammar. It was he who first accurately defined the characteristic features of the several periods of the language and treated the three earliest stages in his works: *Neuägyptische Grammatik* (Leipzig, 1880); *Die Sprache des Papyrus Westcar* (Göttingen, 1889); *Ägyptische Grammatik* (Berlin, 1894). See EGYPT, Language.

That Coptic studies have kept pace with other branches of Egyptology is due to the labors of scholars like Peyron, Schwartz, Tattam, Stern, De Lagarde, Amélineau, Hyvernât, and Steindorff.

Archæological Exploration in Egypt. Archæological research has been carried on in Egypt, with some intermissions, for over a century. In 1798 the Emperor Napoleon took with him to Egypt a scientific commission to explore the monuments of the country, and the results of their investigations are published in the splendid work, *Description de l'Égypte* (Paris, 1809-29), comprising 10 volumes of text and 14 volumes of plates. The work of the commission sent out by King Frederick William of Prussia, which resulted in the publication of the famous *Denkmäler*, has been mentioned above. Important collections of texts and memoirs of travel have also been published from time to time by individual explorers. For the past 50 years both the French and the Egyptian governments have actively fostered the advance of Egyptological studies, and since 1880 the former government has maintained at Cairo a permanent mission (founded by Maspero) for the prosecution of archæological investigations and for training promising students in advanced work. The mission has published a valuable series of memoirs, containing a large number of texts dating from various historical periods, *Mémoires publiées par les membres de la mission archéologique française au Caire* (Paris, 1884 et seq.). The work of the Egyptian Society, the Egyptian Society, founded by Miss Amelia B. Edwards in 1882, has been very fruitful. Many ancient sites have been explored and many interesting discoveries have been made. Up to the present time the society has published more than 50 valuable memoirs, and its annual reports give a comprehensive survey of the progress of Egyptology throughout the world. The British School of Archæology in Egypt as well has published to date 15 monographs on sites and material connected with Egyptian archæology.

A very large number of Egyptian inscriptions and papyri have been published by the different museums and by individual scholars. In this direction, as also in other ways, important service has been rendered by a number of periodicals devoted wholly or in part to the interests of Egyptology. *Zeitschrift für ägyptische Sprache und Alterthumskunde* (Leipzig, 1863 et seq.), *Recueil de travaux relatifs à la philologie et à l'archéologie égyptiennes et assyriennes* (Paris, 1870 et seq.), and *Transactions* (1872 et seq.) and *Proceedings of the Society of Biblical Archæology* (London, 1878 et seq.), deserve special mention in this connection. The *Revue égyptologique* (Paris, 1880 et seq.) deals more especially with Demotic subjects.

Since the time of Champollion, Egyptology has advanced with steady progress and to-day stands upon a firm scientific basis. For the past half century hardly a year has passed unmarked by some important discovery. Among the many scholars to whose labors these great results are due, it is difficult to particularize; but the names of Mariette, Déveria, Pierret, Maspero, De Morgan, Grébaut, and Bouriant, in France, of Hinks, Birch, Le Page Renouf, Wilkinson, Goodwin, Griffith, Flinders Petrie, Newberry, and Budge, in England, of Dümichen, Ebers, Eisenlohr, Wiedemann, Steindorff, Sethe, Von Bergman, and Spiegelberg, in Germany, of Von Lemm and Golenischeff in Russia, of Leemans and Pleyte in Holland, of Rossi, Schiaparelli, and Guidi, in Italy, and of the Swiss scholar Naville, may be mentioned with-

out fear of invidious distinction. The literature of the subject in its various departments is most extensive, and it is unfortunate that no complete bibliography exists. Jolowicz, *Bibliotheca Egyptiaca* (Leipzig, 1858-61), and Prince Ibrahim Hilmy, *The Literature of Egypt and the Soudan, from the Earliest Times to the Year 1885, Inclusive* (London, 1886-88), bring the subject down to 1885. The numerous Egyptian books and articles that have appeared must be sought in the *Orientalische Bibliothek* (Berlin). See EGYPT, and the articles on various special subjects alluded to in this article.

EHEBERG, a'e-bërk, KARL THEODOR VON (1855-). A German political economist. He was born and educated at Munich and in 1882 was called to the chair of political economy at Erlangen. A work of considerable value is his *Finanzwissenschaft* (3d ed., 1891; new ed., 1909), in which the subject of finance is treated in a very thorough and scholarly manner. His other works include *Ueber das ältere deutsche Münzwesen und die Hausgenossenschaften besonders in volkswirtschaftlicher Beziehung* (1879), and *Das Reichsfinanzwesen* (1908).

EHKIBI. See MAHRA.

EHLERS, a'lërs, ERNST HEINRICH (1835-). A German zoölogist. He was born at Lüneburg and was educated at Göttingen and Munich. In 1860 he was appointed professor of zoölogy at Erlangen and in 1874 was called to the chair of zoölogy and comparative anatomy at Göttingen. He also became editor, with A. von Kolliker, of the *Zeitschrift für wissenschaftliche Zoologie*. His principal works are: *Zoologische Beiträge*, with W. Keferstein (1861); *Die Borstenwürmer* (1864-68); *Hypophorella expansa* (1876); *Florida-Anneliden* (1887); *Zur Kenntnis der Pedicellinen* (1890); *Magellanische Anneliden Gesammelt während der Schwedischen Expedition nach der Magellanslandern* (1900); *Neuseelandische Anneliden* (1904).

EHLERS, OTTO EHRENFRIED (1855-95). A German traveler, born in Hamburg. He was educated at Jena, Heidelberg, and Bonn, went to East Africa in 1887, and subsequently visited India, the Andaman and Nicobar islands, as well as Siam, French Indo-China, Korea, and Japan, returning to Germany by way of the Hawaiian Islands and the United States. His second tour took him through India, Samoa, Kaiser Wilhelm's Land, and finally to New Guinea, which country he endeavored to traverse. He was shot by natives accompanying him. His works include: *An indischen Fürstenthöfen* (2 vols., 1883; 5th ed., 1898); *Im Sattel durch Indochina* (1894); *Samoa, die Perle der Südsee* (3d ed., 1896); *Im Osten Asiens* (4th ed., 1900).

EHLERS, RUDOLF (1834-1908). A German Protestant theologian. He was born in Hamburg and was educated at Heidelberg, Berlin, and Göttingen. After holding a pastorate at Stolberg, near Aix-la-Chapelle, he was, in 1864, called to the Protestant Reformed Church at Frankfort-on-the-Main, where he exercised a considerable influence as a theologian, and 14 years afterward was appointed consistorial councillor. In 1879 he became coeditor of the *Zeitschrift für praktische Theologie*. His works include the following: *Evangelische Predigten* (1873); *Das alte Gesetz und die neue Zeit* (1877); *Bilder aus dem Leben des Apostels Paulus* (1886);

Richard Rothe (1906); and a Latin work on the influence of the ancient philosophies upon the Christian apologists of the second century, for which a prize was awarded by the faculty of Göttingen.

EHNINGER, ăn'fing-ēr, JOHN WHETTON (1827-89). An American painter and etcher, born in New York City. He was a pupil of Couture in Paris and afterward studied at Düsseldorf. Among his paintings, which include landscape and figure subjects, are: "Peter Stuyvesant" (1850); "Death and the Gambler"; "Autumn Landscape" (1867); "Twilight from the Bridge of Pau" (1878). He was a clever and versatile draftsman and is perhaps best known for his illustrations of Longfellow's *Miles Standish* (1858) and Irving's *Dolph Heylinger and Ye Legend of St. Gwendolyn* (1867). The drawings for the latter were considered so delicate that they were reproduced by photography—an unusual method in that day.

EHRENBERG, ă'ren-bĕrk, CHRISTIAN GOTTFRIED (1795-1876). A German naturalist, born at Delitzsch. He studied at first theology in Leipzig and then medicine and the natural sciences in Berlin. From 1820 to 1826 he traveled extensively in Egypt and Arabia and afterward accompanied Alexander von Humboldt to the Ural Mountains and Central Asia. In 1826 he became extraordinary professor of medicine in Berlin and in 1839 was made full professor. From 1842 he was perpetual secretary of the Academy of Sciences. Among his earlier works are several books of travels; also *Symbolæ Physicæ seu Icones et Descriptiones Mammalium* (1828-33); *Die Korallentiere des Roten Meeres* (1834). His most important works were on infusoria, his *Infusorien* (1837) which were epoch making. On this subject were: *Organisation systematik und geographisches Verhältnis der Infusionstierchen* (1830); *Die Infusionstierchen als vollkommene Organismen* (1838); *Fossile Infusorien* (1837); *Mikrogeologie* (1854).

EHRENBREITSTEIN, ă'ren-brit'stĕin. A town and fortress of Rhenish Prussia, picturesquely situated on the right bank of the Rhine, directly opposite Coblenz, with which it is connected by a bridge of boats and a railway bridge. It has manufactures of tobacco, leather, flour, bricks, and soap, and carries on a flourishing trade in wine, corn, and iron, and has two cattle markets and four annual fairs. Pop., including garrison, 1900, 5302. The fortress of Ehrenbreitstein occupies the summit of a precipitous rock 385 feet above the river and has been called the Gibraltar of the Rhine on account of its great natural strength and its massive fortifications. The French attempted to take the stronghold in 1688 and failed, but in 1799, after unsuccessful attacks in 1795, 1796, and 1797, and finally a siege of 14 months, they succeeded in capturing it. They retained it only till the Peace of Lunéville (1801), when they retired, blowing up the fortifications behind them. Immediately after the close of the Napoleonic wars the construction of new fortifications on a vast scale was begun, and was completed in 1826 by General Von Aster. The scenery around Ehrenbreitstein is of remarkable beauty.

EHRENSVÄRD, ă'ren-svård, AUGUSTIN, COUNT (1710-72). A Swedish soldier and military engineer. At the age of 24 he invented a device for increasing the force of projectiles. He built the fortifications of Sveaborg (1749)

and created the Swedish coast fleet (1756). For his services in the Seven Years' War he was made a field marshal. There is a fine monument to his memory at Sveaborg.

EHRENSVÄRD, KARL AUGUST, COUNT (1745-1800). A Swedish admiral, author, and art critic, a son of Count Augustin Ehrensward. He became an admiral at the age of 39 and fought the first naval battle of the Russian War, at Svenskund, but was dismissed because of his retreat. After the death of Gustavus III he was reappointed to the chief command of the navy (1792), but resigned two years later. The remaining years of his life were devoted entirely to scientific studies and to the artistic researches which secured for him a high rank as a critic. His principal works are *Resa till Italien* (2d ed., 1819) and *De fria Konsternas filosofi* (1786), in which he evinces a strong predilection for the classics of Greece and Rome. His collected works have been frequently reprinted (latest ed., Stockholm, 1866).

EHRLĖ, ĕrlĕ, FRANZ (1845-). A German Jesuit scholar, born in Isnay, Württemberg. He was educated at Münster, Westphalia, at the Maria-Laach in Freiburg, and at Ditton Hall, Lancashire, having been admitted to the Society of Jesus in 1861. In 1877-78 he was chaplain of Prescott Workhouse and of St. Xavier's, Liverpool, and then for two years he was editor for the *Stimmen von Maria-Laach*. After a decade (1880-90) of historical study in Rome and elsewhere, he became a member of the administrative council of the Vatican Library, of which he was appointed prefect in 1895. He received honorary degrees only from Münster (1902) and Louvain (1903), but from Oxford (1899) and Cambridge (1905). With Denifle (q.v.) he edited (1885 et seq.) the *Archiv für Literatur- und Kirchengeschichte*. Among his many published works mention should be made of *Beiträge zur Geschichte und Reform der Armenpflege* (1881); *Historia bibliothecæ pontificiæ tum Bonifatianæ tum Avenionensis* (1889); a study in French (1899) and Italian (1897) of Pinturicchio's frescoes in the Borgia apartment of the Vatican; and editions of many valuable Vatican manuscripts, particularly those with miniatures.

EHRlich, ĕrlĭk, HEINRICH (1822-99). A German pianist and musical author. He was born in Vienna and studied under Henselt and Thalberg. He was for some time court pianist to King George V of Hanover and became established in Berlin in 1862, where he was made teacher of the pianoforte at the Stern Conservatory (1864-72 and 1886-98). In addition to musical criticisms and other writings in the *Berliner Tageblatt*, *Die Gegenwart*, and the *Neue Berliner Musikzeitung*, his publications include: *Wie übt man am Klavier* (2d ed., 1884; Eng. trans., New York); *Die Ornamentik in Sebastian Bach's Klavierwerken; Dreissig Jahre Künstlerleben 1862-92* (1893); *Schlaglichter und Schlagschatten aus der Musikwelt* (1872); *Aus allen Tonarten* (1888); *Die Ornamentik in Beethoven's Sonaten* (1896); *Musik-Asthetik von Kant bis auf die Gegenwart* (1881); *Modernes Musikleben* (1895). His edition of Tausig's *Technical Studies* is well known.

EHRlich, PAUL (1854-1915). A German physician, famous for his researches in experimental therapeutics. He was born in Strehlen, Silesia, and was educated at Breslau, Strasbourg, Freiburg, and Leipzig, and at the

of M.D. in 1878. In 1885 he was appointed assistant in the University clinic at Berlin, where he became privatdocent in 1889 and in the next year a member of the new Institution for Infectious Diseases and professor in the University. He was appointed (1896) director of the Royal Institute for Serum Research (at Steglitz), which in 1899 was removed to Frankfurt and became the Royal Institute for Experimental Therapeutics. He delivered the Croonian lectures in 1900 and the Harben lectures in 1907, and he received honorary degrees from Göttingen, Chicago (1904), Oxford (1907), and Breslau (1911), many orders and decorations, and, in 1908, the Nobel prize for medicine, with Metchnikoff. He made important studies in the histology of the blood and in immunity reactions and did research work in cancer; devised one of the most important methods of staining for the study of the nervous system; in general, greatly improved the technique of serum propagation; and in particular experimented with fuchsin injections on animals suffering from sleeping sickness; and—his greatest claim to fame and gratitude—discovered salvarsan (Ehrlich, 606) and neosalvarsan (Ehrlich, 614), arsenic compounds, of great efficacy in the treatment of syphilis. His writings include: *Farbenanalytische Beiträge zu Histologie und Klinik des Blutes* (1891); *Wertbestimmung des Diphtherieheilserums* (1897); *Anämie*, with Lazarus (1898); *Experimentelle Carcinomastudien an Mäusen* (1908); *Partialfunktion der Zelle* (1908); *Beiträge zu experimentellen Pathologie und Chemotherapie* (1908); with S. Hata, his assistant in the discovery of salvarsan, *Die experimentelle Chemotherapie der Spirillösen* (1910); *Abhandlungen über Salvarsan* (1911–12). For a popular summary of his work, consult Marks, "Paul Ehrlich," in *McClure's*, vol. xxxvi, pp. 184–200.

EHUD. The name of one of the judges in Israel before the establishment of the kingdom. The "judgment" he brought upon a powerful enemy is described in Judg. iii. 12–30. Having carried tribute to Eglon (q.v.), King of Moab, he departed, but returned, gained admission on the ground that he had an oracle to present, stabbed the unsuspecting King, and delivered his people. As Ehud occurs, in 1 Chron. vii. 10, as the name of a clan, and Gera, his reputed father, likewise in 1 Chron. viii. 3, the historical character of this hero has been doubted. The desire to celebrate the tribe of Benjamin, and especially the zeal of one of its clans, may have led to the story. Consult: Nöldeke, *Untersuchungen zur Kritik des alten Testaments* (Kiel, 1869); Winckler, *Geschichte Israels* (Leipzig, 1875); Moore, *Judges* (New York, 1855); Kittel, *Geschichte des Volkes Israel*, vol. ii (Göttingen, 1909); Wellhausen, *Israelitische und jüdische Geschichte* (7th ed., Berlin, 1914).

ÉIBAR, a'ē-bār. A town in the Province of Guipúzcoa, Spain, 34 miles by rail east by south of Bilbao. It is noted principally for the manufacture of small arms and metal articles for decorative purposes. Pop., 1900, 6459; 1910, 9659.

EIBENSTOCK. ȳben-stōk. A town in the Zwickau District, Saxony, Germany, near the right bank of the Mulde. 17 miles southeast of Zwickau. Its principal edifice is a Romanesque church dating from 1864. It is an industrial

centre, the chief seat of the tambour embroidery manufactures, has manufactures of chemicals, brush handles, leather, beer, and tobacco, and is a cattle market. In the vicinity are tin mines which have been worked since the twelfth century, but are now practically worked out. Pop., 1900, 7468; 1910, 9528.

EICHBERG, ik'bĕrk, JULIUS (1824–93). A German-American musician. He was born in Dusseldorf, studied composition in Brussels under Fétis, and the violin under Meerts and Bériot, and obtained the first prizes in both subjects at the Conservatory. From 1858 until his death he lived in Boston, where he was director of the Boston Conservatory of Music, general supervisor of musical instruments in the Boston public schools, and head of Eichberg's School for Violin Playing. Among his compositions are *The Doctor of Alcántara* (1862), which is one of the best operas written in America, and *The Rose of Tyrol* (1865).

EICHELBERGER, ik'el-bĕrk'ēr, WILLIAM SNYDER (1865–). An American astronomer, born in Baltimore, Md. He graduated (1886) from Johns Hopkins University, assisted (1889–90, 1896–98) on the *Nautical Almanac*, of which he became director in 1910, taught (1890–96) mathematics and astronomy at Wesleyan University, Conn., and after 1900 was professor of mathematics in the United States Naval Academy. After 1902 he was head of various departments in the Naval Observatory, and in 1901 and 1905 respectively he was in charge of the United States eclipse stations at Fort de Kock, Sumatra, and Daroca, Spain. He is author of articles in the *Astronomical Journal* and of papers in government publications.

EICHENDORFF, ik'en-dōrf, JOSEPH, BARON VON (1788–1857). A distinguished German poet, born at Lubowitz, Upper Silesia. He studied at Halle and at Heidelberg, where his poetic talent was awakened by Armin, Brentano, Creuzer, Görres, and others. His early original work included fugitive verse, published under the name of *Florens*, and a prose tale, *Ahnung und Gegenwart* (1811). From 1813 to 1815 he participated in the War of Liberation, and from 1831 until his resignation in 1845 served as an official in the Prussian Ministry of Public Worship and Education. He wrote the last and probably the most important expression of German Romanticism: some, especially *In einem kühlen Grunde*, reaching the popularity of the *Volkslied*. His later poetic work is generally cast in narrative form (*Julian*, 1853; *Lucius*, 1857) and is tinged with increasing clerical views. His admirable translations from the Spanish, *Der Graf Lucanor* (1845) and *Die geistlichen Schauspieler Calderons* (2 vols., 1846–53), were prompted by the same tendency. His most famous prose work is the familiar tale *Aus dem Leben eines Taugenichts* (1826), which retains its popularity throughout Germany. Mention should also be made of a series of literary critiques beginning with *Ueber die ethische und religiöse Bedeutung der neuen romantischen Poesie in Deutschland* (1847); *Geschichte der poetischen Litteratur Deutschlands* (1857). A collected edition of his poems appeared in 1843 (3d ed., 1883), and a selection of his miscellaneous works in 1867 (5 vols.). Consult the study by Keiter (Cologne, 1887), and Krüger, *Der junge Eichendorff* (Oppeln, 1898).

EICHORN, ik'hōrn, JOHANN GOTTFRIED

(1752-1827). A German historian, theologian, and Orientalist. He was born at Dörrenzimmern, Oct. 16, 1752, and studied at Göttingen. In 1775 he became professor of Oriental languages at Jena and in 1788 at Göttingen. Eichhorn's scholarship was very broad and profound, but he is chiefly remembered at the present time as a biblical critic and a leader of the rational school. He first called the attention of German scholars to Astruc's discovery respecting the names for God in the Pentateuch, from which have developed modern ideas of the origin of the names (Urvangelium). His *Introductions to the Old and the New Testament* were the first purely literary historical treatment of the biblical writings. Other noteworthy works are: *Urgeschichte* (1790-93); *Einführung in die apokryphischen Bücher des alten Testaments* (1795); *Übersicht der französischen Revolution* (1797); *Geschichte der drei letzten Jahrhunderte* (1817); *Weltgeschichte* (1818-20). From 1812 he edited the *Göttingen Gelehrte Anzeigen*. Consult Cheyne, *Founders of Old Testament Criticism* (New York, 1893).

EICHHORN, KARL FRIEDRICH (1781-1854). A German jurist and author, born at Jena and educated at Göttingen. He successively occupied the chair of law at Frankfurt-on-the-Oder (1805-11), Berlin (1811-17), Göttingen (1817-28), and Berlin (1832-34). He also filled several important positions in a judicial capacity under the Prussian government. The principal works of Eichhorn, who may rightly be called the founder of the historical school of German jurisprudence, are the following: *Deutsche Staats- und Rechtsgeschichte* (1808-23; 5th ed., 4 vols., 1843-44); *Einführung in das deutsche Privatrecht mit Einschluss des Lehnrechts* (1823; 5th ed., 1845); *Grundsätze des Kirchenrechts* (2 vols., 1821-23; Fr. trans. by H. Jouffroy, 1843).

EICHHORST, IK'hörst, HERMANN LUDWIG (1849-). A German physician, born and educated at Königsberg. In 1877 he was appointed director of the Medical Polyclinical Institute at Göttingen. In 1884 he became professor of pathology and therapy at the University of Zurich. He is the author of the following important works: *Lehrbuch der physikalischen Untersuchungsverfahren innerer Krankheiten* (3d ed., 1891); *Handbuch der speziellen Pathologie und Therapie* (5th ed., 1895-96); *Handbuch der speziellen Pathologie und Therapie innerer Krankheiten* (1904); *Hygiene des Herzens und der Blutgefäße im Gesunden und Kranken Zustande* (1906); *Pathologie und Therapie der Nervenkrankheiten* (1907).

EICHLER, IK'lër, AUGUST WILHELM (1839-87). A German botanist. He was born at Neukirchen and was educated at Marburg. In 1871 he became professor of botany and director of the Botanical Garden at Graz, whence he was called to the chair of botany at Kiel (1873) and Berlin (1878). Very valuable are his writings on the Coniferae, Cycadaceae, and other plant groups of Brazil. His principal work, *Blütendiagramme* (2 parts, 1875-78), advocates and describes the comparative study of the structure of flowers. His other publications include *Spizias der Vorlesungen über spezielle und medizinisch-pharmazeutische Botanik* (1853), in which groups of families (orders) are defined; *Beiträge zur Morphologie und Systematik der*

Marantaceen (1884); *Zur Entwickelungsgeschichte der Palmenblätter* (1885).

EICHRODT, IK'röt, LUDWIG (1827-92). A German jurist and humorous poet, born at Durlach and educated at Heidelberg. His cycle of songs, entitled *Wanderlust*, published by him in the *Fliegende Blätter* at the age of 21, established his popularity as a humorist. In 1848 he founded, at Frankfort-on-the-Main, the humorous-satirical periodical, the *Satyr*. Eichrodt wrote a number of works chiefly distinguished for their parody, such as *Gedichte in allerlei Humoren* (published in 1853 under the pseudonym of Rudolph Rodt; 3d ed. under the title *Lyrische Karikaturen*, 1869); *Rheinschwabische Gedichte in mittelbadischer Sprechweise* (2d ed., 1873); *Lyrischer Kehraus* (2d ed., 1870). Eichrodt's collected poems, *Gesammelte Dichtungen* (Stuttgart, 1890), contain the well-known *Juwallera*, a cycle of modern student songs. Consult Kennel, *Ludwig Eichrodt: Ein Dichterleben* (1895).

EICHSTÄDT, IK'stët, HEINRICH KARL ABRAHAM (1772-1848). A German philosopher, born at Oschatz. He was a student of philosophy at Leipzig in 1795 and of eloquence and poetry at Jena in 1803. He wrote Latin fluently and elegantly. He was a friend of Goethe, in whose honor he wrote the *Oratio Goethii Memoriae Dicata* (1832). He also published editions of the classics and a translation (1802-08) of Mitford's *History of Greece*. Consult *Goethes Briefe an Eichstädt*, ed. by Biedermann (Berlin, 1872).

EICHSTÄTT, IK'stët. A town of Bavaria, situated on the left bank of the Altmühl, about 14 miles northwest of Ingolstadt (Map: Germany, D 4). Its cathedral, begun in the eleventh century, contains some fine stained glass, mural paintings, the tomb of St. Wilibald, and a number of monuments in bronze and marble. The church of St. Walpurgis contains relics of that saint and is visited by pilgrims on May 1, Walpurgis Day. The town hall, dating from 1444, and the old Leuchtenberg Palace of the prince bishops, now used as barracks, are also noteworthy. Eichstätt has also an episcopal lyceum, a theological school, a classical school, and a municipal theatre. It produces beer, lithographic stones, matches, and shoes. The ancient city is supposed to have had its origin in a Roman station. It obtained municipal privileges in 908, when its walls were built, suffered greatly during the Thirty Years' War, and was burned several times by the French during the eighteenth and nineteenth centuries. Pop., 1910, 8029. The bishopric of Eichstätt, founded in 745, was secularized in 1802 and annexed to Bavaria, but a new bishopric was organized in accordance with the agreement of 1817 between Bavaria and the Vatican.

EICHTHAL, äsh'täl', GUSTAVE D' (1804-86). A French publicist, born at Nancy. He was a pupil of Comte, a disciple of Saint-Simon, and a collaborator on the *Organisateur* and the *Globe*. To avoid the attacks upon Saint-Simonism he went to Greece, where he became interested in the rehabilitation of the country, which had been ruined by the War for Independence. His efforts were unappreciated by the Greeks, and he returned to France and gave himself up to authorship. His works include: *Une histoire primitive des races océaniques et américaines* (1845) and *Les origines bouddhiques de la civil-*

sation américaine (1864-65). Some of his essays on biblical criticism were collected and published by his son under the titles *Mélange de critique biblique* (1886) and *La théologie et doctrine religieuse de Socrate* (1881).

EICHWALD, IK'vált, EDUARD GEORG (1838-89). A Russian physician, son of Karl Eduard Eichwald, born at Vilna and educated at the Medico-Surgical Academy at St. Petersburg. He was in ordinary from 1865 to 1875 to the Grand Duchess Helena Pavlovna, who made him the legatee of a sum which enabled him to found the clinical institute subsequently named in honor of its patroness. In 1866 Eichwald was appointed professor of medical diagnosis and general therapy at the Medico-Surgical Academy, and in 1883 he became professor at St. Petersburg. His works, published chiefly in German, include: *Die Kolloidentartung der Eierstöcke* (1864); *Beiträge zur Chemie der gewebebildenden Substanzen* (1873); and a treatise on general therapeutics in Russia (5th ed. by G. Schapiro, 1892).

EICHWALD, KARL EDUARD (1795-1876). A Russian naturalist and traveler, born in Mitau. He studied medicine and the natural sciences at Berlin, Vilna, and Dorpat, and became professor of zoölogy and obstetrics at Kazan in 1823, professor of zoölogy and comparative anatomy at Vilna in 1827, and professor of zoölogy and mineralogy at St. Petersburg in 1838. He traveled extensively for scientific purposes in eastern and northern Russia, in the Caucasus, Persia, Algeria, and throughout Europe. Among his works are: *Zoologia Specialis* (1829-31); *Fauna Caspio-Caucasia* (1841); *Die Urwelt Russlands* (1840-47); *Die Paläontologie von Russland* (1851).

EIDER, ídér. A river of Schleswig-Holstein, Prussia, rising about 10 miles south of Kiel. It is the outlet of the small Lake Redden and flows first northwest, then in a generally westward direction, entering the North Sea at Tönning, its total length being 115 miles (Map: Germany, C 1). In the lower part of its course it is from 600 feet to 1000 feet wide, with a depth of 15 to 18 feet; below Tönning the river expands into a bay. It is navigable from its mouth as far as Rendsburg, from which town navigation is carried on to Kiel by the Schleswig-Holstein Canal, which, prior to the construction of the Kaiser Wilhelm Canal, was the only artificial waterway connecting the North Sea with the Baltic.

EIDER (Icel. æpr, eider). An oceanic duck, having the hind toe furnished with a deep lobe and a bill swollen and elevated at the base

genera. The best known and most important is the American eider (*Somateria mollissima*), which is intermediate in size between a common duck and a goose. The male is larger than the female and in the breeding season has the under parts black, the upper parts creamy white. The female is pale brown, tinged with red, and varied with transverse marks of dark brown. Young males at first resemble the females and do not acquire the full adult plumage and begin to mate and breed until their third year. The eider is an inhabitant of the northern parts of the world, abounding on Arctic and Subarctic shores and in suitable localities from Spitzbergen to the Islands off the northeast coast of England, where it is known as the St. Cuthbert duck. It is also numerous in southern Greenland; and the shores of Alaska and Siberia are inhabited by a very similar species (*Somateria v-nigra*). All these descend to middle latitudes in winter. Two other distinctively American species of the genus exist. One is the American eider (*Somateria dresseri*), which differs from the European bird (drake) mainly in having a black instead of an obscure green patch on the crown and in the shape of the bill (see Plate of NORTH AMERICAN WILD DUCKS in article DUCK); the other is the king eider (*Somateria spectabilis*), which has a v-shaped black mark on the throat. Both breed on the coasts of Newfoundland and Labrador, and the latter goes also to the extreme North, where it is widespread. Both are favorites with sportsmen when they come south in winter along the coast as far as the Middle States and inland to the Great Lakes. Two other species are known—Steller's eider (*Polysticta stelleri*), which is abundant on the Arctic shores of Europe, Asia, and northwestern America; and the spectacled eider (*Arctonetta fischeri*), which seems to be confined to the northwest coast of America. The now extinct Labrador duck was nearly related to them.

Eider Down. The down from the breast of an eider and taken from its nest or from the body of a dead bird for commercial use. The eiders nestle upon coasts, seeking nooks and crannies in which to hide their treasures. As is the habit of many ducks, the mother begins, as soon as the eggs come, to pluck the easily removed down from her breast with which to cover them during her absences, thus both blanketing and concealing them. This down is mouse gray and of the exquisitely soft texture which makes it so valuable. Formerly, as still in Greenland, which furnishes perhaps the largest part of the down sent to market, the down was taken from the wild nests found on coasts. Gradually a certain measure of protection was introduced in some European countries. The next movement was to dig a great number of convenient little hollows or chambers in the soil and among the rocks of sea-fronting hills—accommodations which the ducks were quick to take advantage of. Many such eider folds exist in Norway and Iceland and are regarded as property. The eggs and down are quietly taken from each nest at intervals of a few days by the owners of the eider fold, until the limit of the bird's endurance has been reached, when she is permitted to hatch a few eggs, in order to maintain the race.

About half a pound of eider down is said to be obtained annually from each nest, but this is much reduced by cleaning. Down taken from

BEAK OF KING EIDER.

Side and top views of the bill of *Somateria spectabilis*.

and extending up the forehead, where it is divided down the middle by an elongated projection of feathers. The tertials are elongated and fall down over the wing. The genus is further characterized by the very abundant development of a fine elastic gray down, particularly on the breast, the valuable eider down of commerce.

Several species are known, grouped into three

birds which have been killed is inferior in quality to that obtained from the nests. The latter is known in commerce as "live" down, the former as "dead" down. The elasticity of the down is such that three-quarters of an ounce of it will fill a large hat, while two or three pounds of it may be pressed into a ball and held in the hand. Its use is most extensive in Germany for stuffing bed coverings. For excellent accounts of these birds, consult: Millais, *British Diving Ducks* (London, 1913); Townsend, *A Labrador Spring* (Boston, 1910); id., "A Plea for the Conservation of the Eider," in the *Auk*, vol. xxxi (Cambridge, Mass., 1914).

EIFFEL, i'fel, THE. A bleak and barren plateau situated in the Rhine Province, in southwestern Prussia, between the Rhine on the east, the Roer on the west, and the Moselle on the south. It is in extent 40 miles by 20; the elevation averages from 1500 to 2000 feet, but an extreme altitude of nearly 2500 feet is reached. Its surface is diversified by depressions and ridges that show plainly its volcanic origin. The plateau belongs to the Devonian formation, and volcanic eruptions have brought near the surface in some portions a limestone that is particularly rich in fossils. Above this, in some parts, is found another formation, containing considerable quantities of zinc and lead. The south colored sandstone adds variety to the scenery. In the lower valleys fruit and grain are cultivated, but above 1700 feet the climate is so raw that little grows besides heather. Grazing is extensively carried on.

EIFFEL, á'fel', ALEXANDRE GUSTAVE (1832-). A French engineer, born at Dijon, Dec. 15, 1832, and educated at the Ecole Centrale. He constructed the iron bridge over the Garonne at Bordeaux in 1858 and later the lofty and famous bridge over the Douro at Oporto; also the great viaducts of Garabit in Cantal and of Montluçon; the frame on which Bartholdi's statue of "Liberty Enlightening the World" was built, and the celebrated Eiffel Tower (q.v.), on the completion of which he was made an officer of the Legion of Honor. He also prepared designs for the Panama Canal locks. In 1893 he was sentenced to fine and imprisonment for complicity in the Panama Canal frauds, but the sentence was annulled by the Court of Cassation. His later work was in connection with aerodynamics, and he maintained on the Champ de Mars a well-equipped laboratory for investigation and research, especially on air resistance, one feature of which is an air channel or tunnel in which the effect of air currents from power fans could be studied with immovable models. His *Resistance of the Air*, published in 1913 in an English translation, shows the effect of pressure on various supporting surfaces, the effects of the resistance of various parts of an aeroplane, and the efficiency of propellers. Eiffel's work at the time of its publication was the most systematic discussion of the problems of aerodynamics based on laboratory experiments since the classic researches of Langley in 1891 and afforded aeronautical engineers more accurate data than were ever available previously. See AERONAUTICS.

EIFFEL TOWER. A colossal structure erected in the Champ de Mars, at Paris, by the famous engineer, Alexandre Gustave Eiffel (q.v.). It was completed March 31, 1889, in time to serve as one of the notable features of the exposition of that year. The lower section of the

tower consists of four built-up iron columns, each of which consists of four smaller columns, resting on masonry piers and giving a supporting base 330 feet square. Around each of the four piers is a masonry wall 85 feet square and about 30 feet high, out of which the piers seem to spring. The four main columns curve towards each other until they unite in a single column, 620 feet above the ground. The piers are connected by arches some distance above the ground. There are platforms at the 189-foot, the 380-foot, and the 906-foot levels, which are reached by elevators as well as by stairs. Beyond the third platform a spiral staircase, which is not open to the public, ascends to the top of the tower, which is 984 feet (300 meters) above the ground. In each of the four piers there are elevators; but two of these run to the first platform only and the other two stop at the second platform. A third set of elevators runs between the second and third platforms, or 526 feet, one elevator making half the distance and the other the remainder. Each of these elevators may carry 63 persons. Otis elevators, American make, run from the ground to the second platform. On the first platform, which has a floor space of 38,000 square feet, or nearly an acre, there were four restaurants at the time of the exposition. Searchlights are mounted near the top of the tower, and here is a meteorological observatory, with physical and biological laboratories. The view from the Eiffel Tower extends to a distance of about 85 miles. In the construction of the tower some 7000 tons of iron were used; and the cost was estimated at considerably over \$1,000,000, of which about \$292,000 was voted by the government, while the remainder was supplied by M. Eiffel, who trusted for his reimbursement to the receipts from admission fees during the 20 years for which he is entitled to the profits of the tower. The profits for the year 1889 alone nearly paid for the cost of the tower. The Eiffel Tower more recently has played an important part in scientific research. From here have been suspended lofty antennae used for wireless telegraphy, and the daily time signals under international agreement are sent out into space. Furthermore, in connection with aerodynamic and meteorological research, use has been made of the tower, and many problems involving wind pressure and currents have been studied.

EIGENMANN, i'gen-mán, CARL H. (1863-). An American zoölogist, born at Flehingen, Germany. He graduated in 1886 at Indiana University (Bloomington), studied at Harvard, and was connected with the biological laboratory at San Diego, Cal., and the marine biological laboratory at Woods Hole, Mass. In 1890, 1891, and 1892 he made scientific explorations in Dakota, Montana, Idaho, Oregon, California, and the western part of Canada for the British Museum. He was appointed professor of zoölogy at Indiana University in 1891 and founded there in 1895 a biological station of which he became director. He made scientific explorations in Cuba in 1902-04 and in British Guiana in 1908, and wrote: *Catalogue of Fresh-Water Fishes of Central America and Southern Mexico* (1893); *Cave Vertebrates of America* (1909); *Egg and Development of Conger Eel* (1901); *Fresh-Water Fishes of Western Cuba* (1903); *Fresh-Water Fishes of British Guiana* (1911).

EIGG. An island. See Egg, or Erge.
EIGHTH NERVE. See AUDITORY NERVE.

EIGHT-HOUR DAY. The eight-hour day as the ideal working day was proposed in England as early as 1833. A trade-union congress at Birmingham demanded in 1869 that the eight-hour day should be adopted in the United Kingdom. With the growth of the Democratic Federation in the early eighties, the eight-hour agitation became general. The Socialists sought to secure the desired results through legislation, the trade-unions through combined action against individual employers. The trade-unions, however, have tended to look with more favor upon the gradual establishment of an eight-hour day. The eight-hour day has been adopted by some British municipalities and also for certain classes of work in the public shops. In 1866 the National Trades Union Congress of the United States demanded it. Eight-hour leagues were formed during the strikes of 1872-73. The first law affecting national government employees was passed in 1869 and put into effect in the navy yards. The eight-hour day is now in force for all government work. The eight-hour day on public work conducted directly by governmental agencies is now nearly universal in the United States. In many of the States work on public contracts must also be conducted under the eight-hour system, and in 1912 Congress enacted an eight-hour law for contract work for the Federal government, admitting, however, of certain minor exceptions. An instance of the tendency to extend the influence of the governmental eight-hour system over private industry appears in a provision of the Naval Appropriations Law of 1911: no part of the appropriations made for submarine boats was to be expended for their construction by any person, firm, or corporation which had not at the time of the appropriation extended the eight-hour day to all laborers doing such work.

Even more significant has been the recent tendency, especially in evidence in the Rocky Mountain States, to fix an eight-hour day for workers in various private employments. In Colorado the eight-hour law applies to underground mines and workings, open-pit workings, smelters, reduction works, concentrating mills, and practically all other operations connected with the metal-mining industry. The constitution of Idaho prescribes an eight-hour day for similar work. In Montana an eight-hour day is prescribed by law for underground mines or workings, including railway tunnels. In Nevada the eight-hour day is prescribed not only for underground work in mines, but also for surface work above mines as well as for that of carpenters and other mechanics employed in connection with such work. In Arizona the eight-hour day is prescribed for mines and smelters and similar works. In Pennsylvania the hours of hoisting engineers in mines are restricted to eight. In Missouri the eight-hour day is prescribed by law for silica mining and plate-glass manufacturing; in Louisiana, for stationary engineering.

In 1911 California and Oregon enacted eight-hour laws for women employed in a wide range of occupations. These laws were upheld by the State Supreme Courts, and the Oregon law by the Federal Supreme Court. In 1913 Arizona and Colorado enacted laws restricting women's labor to eight hours. Massachusetts in 1913 enacted a law fixing a limit of eight hours for children under 16 in factories and workshops.

Parallel with the extension of the eight-hour system through legal enactment has been its extension through trade-union activity and through action of private employers. The eight-hour day is widely in force in the building and printing trades, in coal mining, and in certain branches of the metallurgical industries. No statistics are available showing the full extent to which the eight-hour day has been achieved. But it can no longer be held to be exceptional in American industry. In England the mining and metallurgical industries are to a large extent under the eight-hour system, as are also the building trades and a large range of other skilled trades. Unionism has been more largely responsible for the establishment of an eight-hour day in England than in any other country.

On the continent of Europe a widespread agitation in favor of an eight-hour day developed in the last quarter of the nineteenth century. Since 1880 the demand for an eight-hour day has formed a part of the platform of the powerful labor parties of France, Germany, and the Democratic party in Germany. Through the Continent labor organizations and Socialists parties favor the enactment of laws reducing the working day to eight hours. Through the support of the present German Emperor the movement has attained some positive results in Germany. The eight-hour day has been established in some of the industrial enterprises of the government and in a few trades.

In Australia the movement has made greater headway than in any other country. Public sentiment is strongly in favor of a legal eight-hour day. As early as 1856 the stronger trades in Melbourne were able to enforce an eight-hour day, and the movement rapidly spread to the smaller cities of Victoria and to the other colonies. In the Colony of Victoria the hours of women working in the cotton mills were in 1874 limited to eight; in 1885 the same restriction was extended to all employments of women and boys. The eight-hour day was in 1877 prescribed by law for all men working underground; and it has been extended to men employed on many public and quasi-public works. See *LABOR, AMERICAN FEDERATION OF; LABOR PROBLEMS; TRADE-UNIONS*. Consult: Rae, *Eight Hours for Work* (New York, 1894); Hedfield and Gibbins, *A Shorter Working Day* (London, 1894); Robertson, *The Eight-Hour Question* (ib. 1899); National Association of Manufacturers, *Light Hours by Act of Congress* (New York, 1904); *Labor Laws of the United States* (Washington, 1904); Bureau of Labor, *Nineteenth Annual Report: Wages and Hours of Labor* (ib. 1905); House Committee on Labor, *Eight Hours for Laborers on Government Work* (ib. 1906); *Review of Legislation of American Association for Labor Legislation* (1911-).

EIKON BASILIKE, *Ēkōn bā-sīl'i-kē* (Ἔκκον βασιλική, kingly likeness). The name of a book, the full title of which is *EIKON BASILIKH, The Pourtraicture of His Sacred Majesty in His Solitudes and Sufferings* (1648). It was published probably at The Hague and, appearing immediately after the execution of Charles I, professed to be from his Majesty's pen. Milton, in the *Iconoclastes* (1649), assailed it, suggesting doubts also as to its genuineness. The Royalists, on the other hand, warmly defended the theory of royal authorship; but after the Restoration John Gauden, Bishop of Exeter, asked for pro-

motion to the bishopric of Worcester on the ground that he had himself written the book. It is an important fact that the Royalist Clarendon, author of the *History of the Rebellion*, at once accepted this unpalatable statement of the matter. As others, however, refused to credit Gauden, the controversy has raged to the present day. If Gauden was the author, as most authorities now believe, he must have entered thoroughly into the spirit of Charles, though he necessarily idealized the King's character. Consult especially: Wordsworth, *Who Wrote Eikon Basilike?* (Cambridge, 1824); Todd, *Bishop Gauden the Author of Ikon Basilike, Further Shown in Answer to the Recent Remarks of Rev. Dr. Wordsworth* (London, 1825); Toland, *Amyntor* (ib., 1699); Tuckerman, *On the Author of Eikon Basilike* (Berlin, 1874); Godwin, *History of the Commonwealth*, vol. ii, pp. 684 ff. (London, 1826); Hallam, *Constitutional History of England*, vol. ii, pp. 313 f., 636-642 (ib., 1828); Almack, *Bibliography of the King's Book, or Eikon Basilike* (ib., 1896), very valuable. See GAUDEN, JOHN.

EILDON (ēl'don) HILLS. Three peaks in Roxburghshire, Scotland, near Melrose, of traditional interest and celebrated for the extensive view from their summits (Map: Scotland, F 4). The highest is 1385 feet.

EILEEN AROON. See ROBIN ADAIR.

EILEITHYIA (Lat., from Gk. Εἰλειθυία), or **EILEITHYAS/POLIS.** The Greek name of the ancient Egyptian city of Nekheb (the modern El-Kab), situated on the right bank of the Nile, a little below Edfu (Map: Egypt, C 2). From very ancient times it was one of the most important cities of Egypt and was strongly fortified. Its ancient walls still exist in an excellent state of preservation. In Ptolemaic times the city was the capital of the Third Nome of Upper Egypt. The princes of Nekheb played a very important part politically, and many of them were governors of Nubia. The local deity, Nekhbet, was the tutelary goddess of Upper Egypt and the special patroness of the King. She was supposed to preside over birth and was therefore identified by the Greeks with Eileithyia (whence the Greek name of the city) and by the Romans with Lucina. Nekhbet is represented as a vulture with outspread wings, as a woman wearing the crown of Upper Egypt, or as a winged uræus serpent. Near the remains of the ancient city are the ruins of a temple built under Rameses II by Setaw, Governor of Nubia; of another built by Amenophis III and dedicated to the local goddess; and of a third temple built in late Ptolemaic times and likewise dedicated to Nekhbet. All three temples are richly decorated and contain numerous inscriptions. The most important remains at El-Kab are, however, the rock-hewn tombs. Among them are the tomb of the admiral Aahmes, who took part in the expulsion of the Hyksos (q.v.) from Egypt; that of his namesake and younger contemporary, the general Aahmes (Pen-neheb); and that of the nomarch Paheri, tutor to Prince Nazmes, son of King Amenophis I. The two former tombs especially contain inscriptions of the highest historical value. Consult: Wilkinson, *Modern Egypt*, vol. ii (London, 1843); Champollion, *Notices descriptives* (Paris, 1844); Brugsch, *Reiseberichte aus Aegypten* (Leipzig, 1855); Tylor and Griffith, "The Tomb of Paheri at El-Kab," *Egyptian Exploration Fund Memoirs*, vol. xi (London, 1894); Quibell, *El Kab* (ib., 1897).

EILENBURG, il'en-bōōrk (anciently called *Ilburg*). A town of the Prussian Province of Saxony, situated mainly on an island in the river Mulde, about 15 miles northeast of Leipzig (Map: Germany, E 3). It has large manufactures of calico, yarn, cloth, dyestuffs, vehicles, basketwork, tobacco, chemicals, celluloid, beer, and agricultural implements. Franz Abt the song writer and M. Rinckart the poet were born here. Pop., 1900, 15,147; 1910, 17,401. Consult Gundermann, *Chronik der Stadt Eilenburg* (Eilenburg, 1879).

EIMBECK. See EIMBECK.

EIMBECK, im'bēk, WILLIAM (1841-). An American geodesist, born in Brunswick, Germany. He was an assistant civil engineer in the public offices of St. Louis, Mo., a professor for two years in Washington University, St. Louis, and a member of the United States solar eclipse expeditions of 1869 (to Illinois) and 1870 (to Italy). After 1871 he was an assistant on the United States Coast and Geodetic Survey. His most important work was in connection with the thirty-ninth parallel triangulation (Western division) and with the invention of the invariable reversible pendulum and the duplex base apparatus employed in the Geodetic Survey.

EIMEO. See MOOREA.

EIMER, i'mēr, THEODOR (1843-98). A Swiss-German zoölogist, born in Stäfa. He studied medicine and the natural sciences in Heidelberg, Würzburg, Freiburg, and Berlin. In 1870 he became privatdocent in Würzburg and in 1875 professor of zoölogy in Tübingen. In 1878-79 he made a scientific journey to Egypt. He wrote: *Zoologische Studien auf Capri: Beroë Ovatus und Lacerta Muralis Cærulea* (1874); *Die Medusen* (1879); *Untersuchungen über das Variieren der Mauereidechse* (1881); *Die Entstehung der Arten auf Grund der Vererbung erworbener Eigenschaften* (1888; 1897); *Artbildung und Verwandtschaft bei den Schmetterlingen* (1889; 1895).

EIMÉRICO, NICOLÁS. See EYMERICUS, NICOLAS.

EINBECK, in'bēk, or **EIMBECK.** An old town in the Prussian Province of Hanover, on the Ilme, about 40 miles south-southeast of Hanover (Map: Germany, C 2). The Alexanderkirche contains the tombs of the princes of Grubenhagen, a fine bronze baptismal font, and some old choir chairs. Its schools teach technical -u'j' -l- such as machinery construction and w'aving: i has also a police school. Its manufactures include belts, linen, carpets, sugar, tobacco, and roofing felt. The famous Eimbecker beer, which has given its name to the well-known term "bock," is still brewed to a considerable extent. Pop., 1900, 7914; 1910, 9431. Einbeck grew up around a cathedral chapel reputed to contain the blood of the Saviour and visited by throngs of pilgrims. It was a member of the Hanseatic League, but in 1626 was captured by Pappenheim. In 1641 by Piccolomini, and in 1761 by the French, who dismantled its fortifications. Consult H. L. Harland, *Geschichte der Stadt Einbeck*, vol. ii (Einbeck, 1854-59).

EINHARD, or **EINHART**, in'härt, frequently called **EGINHARD**, a'gin'härt (c.770-840). The biographer of Charlemagne the Great. He received his early education in the monastery of Fulda, where he did so well that he was sent to the school in the palace of Charles the Great. His talents and acquirements gained

him the favor of the Emperor, who appointed him his private secretary and superintendent of public buildings. In 806 he was dispatched by Charles on a mission to Pope Leo III. On the death of the Emperor he was appointed by Louis the Pious abbot of various monasteries, but ultimately he retired to the town of Muhlheim. Here he erected a monastery, which caused the name to be changed from Muhlheim to Seligenstadt (City of the Blessed). Einhard died on March 14, 840, and was buried beside his wife, who died in 836. The two coffins are now shown in the chapel of the castle at Erbach. The counts of Erbach trace their descent from Einhard. His *Vita Caroli Magni*, completed about the year 820, in respect to plan, execution, language, and style, is incontestably the most important historical work of a writer of the Middle Ages. It was frequently used as a school-book and was therefore copied *ad infinitum*. His *Epistolæ* are also of great value for the history of the later years of Louis the Pious. Einhard also wrote an account of the translation of the relics of Saints Marcellinus and Peter from Rome to Seligenstadt. To Einhard also are ascribed the so-called *Annals of Einhard* and a rhythmical *Passion of the Martyrs Marcellinus and Peter*. According to a legend of the later Middle Ages, Einhard's wife, Emma, was a daughter of Charlemagne. Love had arisen between them, and on one occasion, when the two had clandestinely met at night in Emma's chamber, a sudden fall of snow covered the spacious court, thus rendering retreat impossible without leading to discovery. As the traces of feminine footsteps could not excite suspicion, Emma carried her lover across the court on her shoulders. This scene, it is said, was observed from a window by Charlemagne, who united the pair in marriage. On this legend Fouqué founded his romance of *Eginhard und Emma*, and Longfellow has made it the subject of a short poem. For the editions of Einhard's works and for special studies, consult Wattenbach, *Deutschlands Geschichtsquellen*, vol. i (Berlin, 7th ed., Stuttgart, 1904), and Molinier, *Les sources de l'histoire de France*, vol. i (Paris, 1902).

EINSIEDELN, in'zè-dèln. A town in the Canton of Schwyz, Switzerland, 2895 feet above sea level, and 26 miles southeast of Zurich. It is one of the most famous pilgrim resorts in the world, being visited yearly by 160,000 transients, most of whom come from Switzerland and southern Germany (Map: Switzerland, C 1). There are numerous hotels and inns for the worshippers. The principal industry is the manufacture of images of saints, crucifixes, and other devotional objects that are exported to all parts of the world. The road up to the celebrated Benedictine monastery of Einsiedeln, which is 2900 feet above the village, passes the house where Paracelsus (q.v.) is said to have been born. The monastery buildings, in the midst of a gloomy forest that was once extensive, and surrounded by a quadrangle of walls, were six times partially or entirely destroyed by fire before the seventeenth century. In 1704-19 they were rebuilt in the Italian style. At the entrance of the church are statues of the emperors Otho I and Henry II. In a large court is a black marble fountain with 14 jets, surmounted by a statue of the Virgin, from which pilgrims drink. In the nave is the black marble chapel containing the renowned miracle-working image

of the Virgin, richly bedecked and bejeweled. This is the "sanctum sanctorum" of the pilgrims. The gorgeous chandelier was given by Napoleon III in memory of his mother. The monastery has a library of 61,800 volumes and 1200 manuscripts, a seminary, a gymnasium, and a lyceum. It owes its origin to the hermit Meinrad, who erected a chapel for the image of the Virgin which had been given him by the Abbess Hildegard, and which has made Einsiedeln one of the most famous of Catholic pilgrimages. The founder of the monastery was Eberhard, provost of Strassburg, who began the building in 934. Pop., 1900, 8469; 1910, 8438. The vicinity affords fine views of the Alps and the Lake of Lucerne. Consult Brandes, *Die Feier des tausendjährigen Bestehens von Maria Einsiedeln* (Einsiedeln, 1862), and O. Ringholtz, *Geschichte des fürstlichen Benediktinerstiftes Einsiedeln*, vol. i (ib., 1904).

EIRE, JUSTICES IN. See EYRE, JUSTICES IN.

EISELEN, ʔze-len, ERNST WILHELM BEINHARD (1793-1846). A German promoter of athletic exercise, born in Berlin. He established the terms still used in German fencing. In 1818 he opened a public gymnasium in Berlin, which was followed in 1832 by one especially designed for the gymnastic training of girls. He was one of the foremost promoters of those athletic exercises which have directly and indirectly contributed to the physical improvement of the Germans, becoming bases of military training and conducing to the splendid successes achieved by the German arms during the nineteenth century. It is interesting to note that it was largely from these transplanted gymnasia, or *Turnvereine*, that some of the best German volunteers of the Civil War in the United States were recruited. The literary productions of Eiselen include: *Deutsche Turnkunst*, in association with Jahn (1816); *Hantelübungen* (1833; 3d ed., 1883); *Abbildungen von Turnübungen* (1845; 5th ed., 1889); *Das deutsche Hiebfechten* (1818; new ed., 1882); *Abriss des deutschen Stossfechtens* (1826; new ed., 1889).

EISENACH, ʔze-näg. A town and summer resort of the Grand Duchy of Saxe-Weimar, and former capital of the Principality of Saxe-Eisenach, situated at the northwest end of the Thuringian Forest, where the Nesse meets the Hörsel, 32 miles west of Erfurt (Map: Germany, D 3). The town is well laid out, with a number of beautiful squares, one of which, the Lutherplatz, contains the house where Luther lived while studying at Eisenach, and another, Karlsplatz, is adorned with a bronze statue of Luther. The most noteworthy ecclesiastical edifices are the church of St. Nicholas, dating from the twelfth century, with an octagonal tower; the church of St. George, a large Gothic edifice with a bronze statue of Sebastian Bach, a native of Eisenach. Other interesting buildings are the palace, erected in 1742, once residence of the Duchess Hélène of Orléans; the town hall; the Klemnda, a small castle dating from the thirteenth century; the theatre; the house where Bach was born and another where Fritz Reuter lived. Not far from the town, on a lofty eminence, is the castle of Wartburg, the residence of the mediæval landgraves of Thuringia, dating probably from the eleventh century and restored. It consists of two main parts, the Vorburg and the Hofburg—the former containing the Ritterhaus and stables and the latter the apartments of the landgraves. In

one of the rooms of the Vorburg, Luther worked on his famous translation of the Bible. The Hofburg contains many halls of great splendor, including the " " where, according to local tradition, the contests of the Minnesingers were held under the patronage of the Landgrave Hermann I (1190-1217), as described in the old poem *Krieg von Wartburg*. The castle is now occasionally occupied by the Grand Duke of Weimar.

Among the educational institutions of Eisenach, the most prominent is the gymnasium, formerly a Latin school, which Luther and Bach once attended, a school of forestry, a school of design, and a teachers' seminary. Eisenach has some well-developed manufacturing industries and produces paint, chemicals, woolen goods, leather, pottery, shoes, tobacco, cigars, cement, pipe, alabaster ware, cabinetwork, and lumber. The neighborhood is remarkably picturesque, being ornamented with splendid gardens and residences. The town was founded in 1070, near the older town of Isenach, or Isenacum. It prospered under the protection of the landgraves of Thuringia, the owners of the Wartburg, and was from 1596 to 1741 the residence of the princes of Eisenach. Pop., 1900, 31,442; 1910, 38,362. Consult: Storch, *Beschreibung der Stadt Eisenach* (Eisenach, 1831), and Jäger, *Eisenach und die Wartburg* (ib., 1871); Warnatz, *Die Wartburg und Eisenach in Sage und Geschichte* (Vienna, 1881); Scheller, *Eisenach und Umgebung*, ed. by Kühner (Eisenach, 1898).

EISENACH CHURCH CONFERENCE, or EVANGELICAL CHURCH CONFERENCE. The name given to periodical meetings of representatives of the Protestant churches of the German states and Austria. The first was held at Berlin in 1846 and included representatives from nearly all the German states; the second at Eisenach, in 1852; and since 1854 they have been held every two years at the latter place. The aim is the discussion of questions of general interest and the promotion of unity among the individual churches. Since 1852 the conference has published at Stuttgart a central organ, the *Allgemeine Kirchenblatt für das Deutsche Reich*. Consult Braun, *Zu Eisenach. Die engere Vereinigung der Deutschen evangelischen Landeskirchen* (Berlin, 1902).

EISENBERG, ʔzen-bĕrk. An old town in the Duchy of Saxe-Altenburg, Germany, near the junction of the Saale and Elster, 36 miles southwest of Leipzig. It contains a ducal palace, with a fine church and gardens, and manufactures woolens, velvet, pottery, furniture, pianos, porcelain, and agricultural machines. Statues have been erected to Bismarck, Duke Christian of Saxe-Eisenberg, and the philosopher Karl Christian Friedrich Krause. Pop., 1900, 8764; 1905, 9956; 1910, 10,749. Consult *Chronik der Stadt und des Amtes Eisenberg* (Eisenberg, 1843).

EISENERZ, ʔzen-ĕrts. A market town of Styria, Austria, 2350 feet above sea level, on the Erzbach, 24 miles northwest of Leoben (Map: Austria, D 3). The Gothic church of St. Oswald, founded in 1279, is an excellent example of the fortified type of ecclesiastical architecture. The town derives its importance from its proximity to the Erzberg, a mountain about 5000 feet high, containing valuable deposits of iron ore. About 4500 miners are employed in the quarries on the mountain in summer and 2000 in winter, the annual output being about 1,000,-

000 tons, of which about 40 per cent is metal. Aragonite (*Eisenblute*, or *flos ferri*), resembling branching coral in form and of the most beautiful and purest white, is found in grottoes in the interior of the mountain. Pop., 1890, 5700; 1900, 6494.

EISENHART, ʔzen-hărt, LUTHER PFAHLER (1876-). An American mathematician, born at York, Pa. He graduated from Gettysburg College in 1896, took the degree of Ph.D. at Johns Hopkins University four years later, was instructor and preceptor at Princeton University from 1900 to 1909 and thereafter professor of mathematics. In 1913-14 he was a vice president of the American Mathematical Society. Besides contributions to journals, he is author of *Differential Geometry* (1909).

EISENLOHR, ʔzen-lôr, AUGUST (1832-1902). A German Egyptologist, born in Mannheim. He studied theology at Heidelberg and Göttingen and later became interested in the natural sciences and the manufacture of chemical products, abandoning both, however, for the study of Egyptology. In 1872 he was made an extraordinary, and in 1885 full, professor at Heidelberg University. His chief works are: *Der grosse Papyrus Harris* (Leipzig, 1872); "The Political Condition of Egypt before the Reign of Rameses III," in the *Transactions of the Society of Biblical Archaeology* (London, 1872); *Ein mathematisches Handbuch der alten Aegypter* (Rhind papyrus of the British Museum, trans. with explanatory notes, Leipzig, 1877).

EISENLOHR, THEODOR (1805-69). A German divine and educator. He was born at Herrenberg and studied theology at Tübingen. After holding several pastorates and conducting the seminary at Nürtingen, Württemberg, he became a member of the consistory and a counselor of the Board of Public Instruction in that city. He was editor of the departments of ecclesiastical and educational law in Reyscher's *Sammlung der württembergischen Gesetze*, vols. viii, ix, and xi (1834-39), and published *Das Volk Israel unter der Herrschaft der Könige* (2 vols., 1855-56), in which he endeavors to show the great importance of biblical history as an educational factor, and *Die Idee der Volksschule nach der Schriften Fr. Schleiermachers* (1852).

EISENLOHR, WILHELM (1799-1872). A German naturalist, born at Pforzheim. He studied natural history and physics at Heidelberg and became professor of physics at the Polytechnical Institute at Karlsruhe in 1840. He established the first industrial school of Baden, at Mannheim, and assisted in the organization of all similar institutions afterward erected in that grand duchy. His principal publication is the popular textbook entitled *Lehrbuch der Physik* (1836; 11th ed., 1876).

EISENMENGER, ʔzen-mĕng'ĕr, AUGUST (1830-). An Austrian mural painter, born in Vienna. He studied at the Vienna Academy (1845-48) and in 1856 became the pupil and assistant of Rahl. From 1872 to 1901 he was a professor in the Academy. His more important works include the frieze medallions in the Museum of Art and Industry, Vienna; a series of historical pictures illustrative of the reign of Emperor Maximilian I, in Castle Hörsenstein, near Vienna (1872-79); and the decorative painting in the session room of the Chamber of Deputies in the Reichsrat building at Vienna (1885).

EISENMENGER, JOHANN ANDREAS (1654–1704). A German Hebraist and anti-Semitic writer, born at Mannheim. Because of his scholarly achievements while a student of Hebrew at the Collegium Sapientiae in Heidelberg, he was sent to England and Holland by Charles Louis, Elector of the Palatinate. He spent some time in Amsterdam and subsequently devoted himself for many years in Heidelberg, and, after the capture of this city in 1693, at Frankfort, to the study of Hebrew literature. He was appointed professor at Heidelberg by the Elector, John William, in 1700. His principal work was entitled *Entdecktes Judentum*. It was first published at Frankfort in 1700, but was confiscated by the Emperor, who ordered the whole edition to be placed under lock and key. Eisenmenger died suddenly of apoplexy in 1704. King Frederick William I of Prussia ordered a new edition to be printed in Berlin, which appeared in 1711, at Königsberg as the place of printing, as the prohibition applied to Berlin. It was compiled from nearly 200 Hebrew and about 12 Judeo-German sources and included material drawn from books written by converted Jews. Delitzsch has shown the many inaccuracies of translation in this work, and Siegfried the numerous misinterpretations and wrong inferences due to the author's bias. It has been used as a storehouse by enemies of the Jews, who have often drawn from it charges devoid of all foundation. The substance of the work was presented in English by Stekelin, under the title *The Traditions of the Jews, with the Expositions and Doctrines of the Rabbins* (1732–34). A new edition of the original was published by Schiefferl (1892). Consult: A. Th. Hartmann, *Johann Andreas Eisenmenger und seine jüdischen Gegner* (1834); Röhling's *Talmudjude beleuch.* Siegfried, in *Deutsche Biographie*, vol. v, pp. 772 f.; G. Dalman, in *Herzog-Hauck's Real-Encyclopädie*, vol. v, pp. 276 f.

EISENSTADT, ʔzen-stät, or KISMARTON. A town of Hungary, County of Odenburg, in the centre of rich vineyards, at the foot of the Leitha Mountains, about 25 miles south-east of Vienna (Map: Austria-Hungary, E 3). Its chief architectural feature is the magnificent palace of Prince Esterházy, erected in 1683 and enlarged in 1805. The palace is situated amid fine grounds, and its library is particularly rich in musical manuscripts. In the church of the Franciscan monastery is the burial vault of the Esterházy family. Near the town is the church of Maria-Einsiedel, a favorite resort of pilgrims and the burial place of the composer Joseph Haydn, who was the conductor of Prince Esterházy's orchestra from 1760 to 1790. Pop., 1900, 3067; 1910, 3073.

EISENSTEIN, ʔzen-stin, FERDINAND GOTTHOLD MAX (1823–52). A German mathematician, born in Berlin. He wrote for Crelle's *Journal* at the age of 15, secured his doctor's degree after only three semesters at Breslau, was adjunct professor at that university at 24, and was a member of the Berlin Academy at 29. Although he died before he was 30, his literary work was extensive. He wrote on the theory of numbers, theory of functions, and other branches of higher mathematics, 37 of his memoirs being found in the first 50 volumes of Crelle. Gauss ranked him with Archimedes and Newton in point of natural ability in mathematics. There is a biography by Rudol,

with some autobiographical matter, in the *Monatsschrift zur Geschichte der Mathematik*, viii (Leipzig, 1895).

EISELFELD, is'fêlt, THEODOR (1816–82). A German-American musician and conductor. He was born at Wolfenbüttel, Germany, and when but 23 years of age was appointed kapellmeister of the Court Theatre of Wiesbaden, which position he held for four years (1839–43), going afterward to Paris, where he had the direction of the *Concerts Vivienne*s. In 1848 he moved to New York and became one of the leading factors of musical America, taking an especially active part in the musical life of New York. He was the conductor of the Philharmonic and of the Harmonic societies and, in connection with Noll, Reyer, and Eichhorn, established the celebrated quartet *soirées* of 1851. A nervous affection caused by shock arising from the burning of the ocean steamer *Austria* (in 1865), of which he was one of the few survivors, cut him off from all further musical activity. He died at Wiesbaden.

EISK. See YEISK.

EISLEBEN, is'lä'ben. A town of the Prussian Province of Saxony, situated about 18 miles west-northwest of Halle (Map: Prussia, D 3). It is the centre of a rich mining district and consists of the old town, new town, and three suburbs. Martin Luther was born at Eisleben in 1483 and died here in 1546. The house in which he was born, partially destroyed by fire in 1689, was rebuilt through voluntary contributions and converted into a free school. The house where he died has also been restored and contains numerous relics. The church of St. Andrew contains Luther's pulpit, busts of Luther and Melancthon, and monuments of the counts of Mansfeld. In the church of St. Peter and St. Paul are preserved the font in which Luther was baptized, his leather cap, and a fragment of his cloak. The town has a gymnasium, founded by Luther two days before his death. The chief industry of Eisleben is the smelting of copper and silver, from nearby mines. Pop., 1900, 23,900; 1910, 24,629. Eisleben, known in the tenth century as Is-lebin, came into possession of the counts of Mansfeld in the twelfth century, to whom it belonged until the extinction of that line in 1780; then it passed to Saxony and, in 1815, to Prussia.

EISTEDDFOD, äs-têp'vôd (Welsh, from *eistedd*, to sit, and *bod*, to be; pl. *eisteddfodau*). A Welsh word, meaning literally "sitting," or "session." It is applied to the assemblies of bards and people meeting for competition in Welsh poetry and prose and in music, both vocal and instrumental. There are two kinds of *eisteddfodau*—the national or general body, and the provincial gatherings which take place in many parts of Wales and even among the Welsh in foreign countries, especially in the United States. Though the institution bears all the marks of antiquity, the meetings which are traditionally ascribed to the fifth, sixth, and seventh centuries can hardly be deemed historic. Originally the principal function of the *eisteddfod* was to license or admit duly qualified candidates to the position of recognized bards or minstrels. This position included many privileges, among them the right to a billet which every nobleman was bound to respect. About the year 1100 Gruffyd ab Cynan is supposed to have held a great national eis-

teddfod at the ancient town of Caerwys in Flintshire, and in 1176 Lord Rhys (Rhys ab Gruffyd) is known to have held at his castle of Cardigan a grand festival with both poetical and musical competitions—the earliest eisteddfod of which we have any actual account. In the twelfth century it had become a regularly constituted court. Again, in the time of the Tudors we find the eisteddfod recognized as a tribunal of authority, and Queen Elizabeth in 1568 issued a commission for holding one. In the seventeenth century, because of the unsatisfactory condition of the Welsh professional world, the eisteddfod seems to have fallen into abeyance. The last petition to hold one, of which we have any note, was made by the gentry of North Wales in 1594 and was apparently not granted. During the nineteenth century it was revived and has now become an institution of prime importance for the intellectual life of the Welsh people. The national gathering is held every year in North and South Wales alternately and is attended by many thousands of people. While it has achieved success in encouraging literature and music, it has accomplished little towards the development of art. Consult Rhys and Brynmor-Jones, *The Welsh People* (London, 1909). The programmes of some recent eisteddfodau have been published in *Y Cymmrodor*. See BARD.

EITELBERGER VON EDELBERG, *Eitelbérk'ér fón á'del-bérk*, RUDOLF (1817-85). An Austrian art historian, born at Olmütz. He was made professor of the history of art at the University of Vienna in 1852 and in 1864 took an active part in the founding of a School of Decorative Arts and of the Museum of Arts and Industries at Vienna, of which he remained the director until his death. His works, critical and historical, have done much to stimulate the study of art and to promote the industrial arts in Austria. Among them are: *Die Reform des Kunstunterrichts* (1848); *Mittelalterliche Kunstdenkmale des österreichischen Kaiserstaats* (1858-60); and, in collaboration, *Quellenschriften für Kunstgeschichte und Kunsttechnik des Mittelalters und der Renaissance* (1871-82); *Gesammelte kunsthistorische Schriften* (4 vols., 1879-87).

E/JA (Egypt). The desert saw viper. See SAW VIPER.

EJECTMENT (from *eject*, from Lat. *ejicere*, to throw out, from *e*, out + *jacere*, to throw), ACTION OF. An action brought to recover possession of land and also to obtain damages for its being wrongfully withheld from the person who brings the suit. This, in the common-law practice, is the only surviving instance of a mixed action; i.e., one partaking in part of the nature of a real action for the recovery of the land, in part that of a personal action for damages. The origin of the action is to be found in the old writ of *ejectio firmæ*, or *termæ* (ejectment for a term of years), which (originally only an action in trespass whereby a tenant for years could recover damages for an eviction or ouster) was so shaped as to entitle him to recover the possession of his lands. Being a simpler and more expeditious remedy than the various possessory actions provided by the common law, such as the writ of *novel disseisin*, and the like, for recovering the possession of freehold lands, it came in process of time to be employed for this purpose in all cases of wrongful dispossession until it had

completely superseded the more cumbersome remedies afforded by the common-law writs.

The process of establishing title to real estate by this action was formerly—and still is in some jurisdictions—a most intricate and serious one. As has been said above, the original action of ejectment was brought, not to try the title to the land nor to recover the land itself, but to enable a tenant for years to recover damages for the injury sustained on account of being deprived of the use of the land. Thus, the action could be brought only by, or in the name of, a tenant for years, and the plaintiff was required to show (1) good title in the owner alleged, (2) a lease by him to the plaintiff, (3) entry on the land by the plaintiff, and (4) ouster from the land. But as, when it was desired to test the question of title or to recover the possession of the land, this state of facts very likely might not exist, and as common-law procedure had provided no other way of testing the title, a series of fictions was introduced to meet these requirements. The plaintiff in ejectment thus became a fictitious tenant, suing under the name of "John Doe" (q.v.) in behalf of the person (alleged to be his lessor) who was really claiming possession.

In England this form of action of ejectment was abolished in 1852, though the name was still retained. By the judicature acts of 1875 actions for the recovery of land were placed on the same footing as other actions, and what had been retained of the old common-law action was superseded by a simple and uniform method. Legislation to a similar effect has been adopted in several of the United States; in others the action of ejectment is maintained in much the same condition in which it was left after the English Act of 1852; in a very few others the ancient form is still in use. The remedy given by an action of ejectment is one that may ordinarily be used for the recovery only of corporeal property, not of incorporeal hereditaments, such as an easement or a profit *à prendre*, though there are a few instances of its use for the latter purpose also; nor will such an action lie to recover personal property. An action of ejectment may be brought by any one who has the legal right to enter and possess the land, without regard to the exact character of his estate therein; and any person may be made defendant who has wrongfully seized or held the property under a claim of right against one holding a lawful estate therein. The burden of proof of title lies with the plaintiff, the presumption of law being in favor of the actual possessor, who need not, therefore, prove his own title otherwise than against the plaintiff. The verdict in an ejectment suit is for the plaintiff to recover peaceable possession of the land or for the defendant to retain his possession. Under the old practice the damages which might be given to the plaintiff, together with possession, were purely nominal; a supplementary suit was necessary if substantial damages were really demanded. But under the later English practice and in most of the United States substantial damages may be granted in the original action. Such damages may also be in the nature of an accounting for mesne, or intermediate, profits. Consult: Blackstone's *Commentaries on the Laws of England*; Stephen, *New Commentaries on the Laws of England* (14th ed., London, 1903); Digby, *Introduction to the History of the Law of Real*

ΕΛΕΑΓΝΑ/CEÆ. See ELÆAGNUS.
ΕΛÆAGNUS (Neo-Lat. from Gk. *ἑλαιαγνος*, *elaiagnos*, *ελεαγνος* s. *σινος* gale. *πικρία*, from *δαία*, *δαίη*, olive tree = *ἄγιος*, *αγιος*, tree like a willow). A genus of dicot. leucous plants, of the family Elæagnaceæ. This family consists of trees and shrubs, usually covered with scurfy scales and having alternate or op-

EL'AGAB'ALUS, incorrectly **HE'LOGAB'ALUS** (204-222). Emperor of Rome from 218 to 222. He was born at Emesa, Syria. His real name was Varius Avitus Bassianus; but having, when a mere child, been appointed high priest of the Syro-Phœnician sun god Heliogabal, he assumed the name of that deity. Soon

after the death of his cousin Caracalla, Elagabalus was proclaimed Emperor by the soldiers, in opposition to the sovereign, Macrinus, who had imposed his rule from the severity of his discipline. The rivals met in battle at Antioch in 218 A.D. Macrinus was defeated, and Elagabalus quietly assumed the purple. His reign, which lasted rather more than three years and nine months, was infamous for the almost unparalleled debaucheries in which he indulged. He was murdered in an insurrection of the prætorians on March 11, 222, and was succeeded by his cousin and adopted son, Alexander Severus. Consult Duviquet, *Héliogabale* (1903), and Butler, *Studies in the Life of Heliogabalus*, in "University of Michigan Studies: Humanistic Series," vol. iv (1908).

ELAINE, è-lān'. A favorite woman's name in the Arthurian legends. 1. The half sister of Arthur, who bore his illegitimate son, Modred. 2. King Pelles's daughter, who bore Sir Galahad, Launcelot's son. 3. The maid of Astolat, who died for love of Launcelot, and whom Tennyson has celebrated in the poem *Elaine*. 4. The daughter of King Brandegori, who had a child by Sir Bors de Ganis. 5. Launcelot's mother, the wife of Ban of Brittany.

ELAIOMETER. See OLEOMETER.

ELAIOPLASTS. From Gk. *ἐλαίον*, *elaion*, olive oil + *πλασσειν*, *plassein*, to shape). Protoplasmic bodies, containing imbedded oil drops, which occur in the epidermis of various lilies and orchids. They are believed by their discoverer, Wakker, to have the function of accumulating oil in much the same fashion as the leucoplasts accumulate starch. See LEUCOPLASTS.

ELAIOSOMES, è-l'ā-sōmz (from Gk. *ἐλαίον*, *elaion*, olive oil + *σῶμα*, *sōma*, body). The seeds of certain plants have upon them external oil bodies, or elaiosomes, that cause them to be transported by ants which use the oil bodies for food. These bodies form various appendages to seeds and fruits, but are usually more or less prominent ridges or knobs near their point of attachment. See MYRMECOPHORY.

ELAM. A country including the high plateau traversed by the Zagros and Pushti chains and the great plain east of the lower Tigris and north of the Persian Gulf. It corresponded in a general way to the modern Khuzistan, in part to the Susiana and Elymais of the Greek classical writers. The name is derived from the Assyrian *Ilamtu*, 'the highlands,' and seems to be a translation of the Sumerian *Nimma*. The native designation appears to have been *Shushunka-Anshan*. *Shushunka* was the source of the Greek name *Susiana* and denotes the territory ruled from the capital *Shushan*. (See *SUSA*.) *Anzan*, or *Anshan*, is a more ancient native name and indicates the region subject to the city of *Anzan*. The situation of this city has not yet been definitely identified, but it is so closely connected with *Susa* that it may have been a twin city inhabited chiefly by the native element. (See *ANZAN*.) In later times the name seems to have been used of the whole territory. Cyrus apparently reigned in *Susa* as King of *Anshan*. The Greek *Elymais* was derived from the Semitic name and was probably identical with *Susiana*. From the highlands descended the great rivers of *Elam*, the *Karun* (*Ululaj*, *Eulaios*), the *Kercha* (*Uknu*, *Choaspes*), and others. The valleys were ex-

ceedingly fertile, while in the southwestern plains the heat may not have been so intense in ancient times as at present. As to the ethnic relations of *Elam* in antiquity, our knowledge is yet quite scanty. It is impossible to determine how long those races have been in the land that are found there to-day. The negroes may be a comparatively late importation. Recent research renders it probable that the *Arrians* were in the land at a much earlier date than has been supposed. Semitic *Akkadians* were there already in the time of *Sargon I* of *Agade*. "Turanian" elements are more likely to have found their way into the country in the last 1000 years than in earlier periods. The mass of the people may have belonged to the large family of nations of which the people of the *Caucasus* are the present representatives. There is a certain similarity between the *Elamitic* dialects and the *Georgian*, *Udic*, and *Guric* languages, which suggests this. The dialects in which inscriptions have been preserved are (1) the Old *Elamitic*, (2) the *Anzanian*, (3) the *Mal Amir*, (4) the *Susian* dialect. Another dialect, the *Kashite*, is known through *Babylonian* inscriptions. Partly through these records, which have greatly multiplied in recent times through the French excavations at *Susa*, and partly through *Babylonian* and *Assyrian* sources, light is thrown upon certain periods of the history of ancient *Elam*. *Eannatum* of *Lagash* fought with *Elam*; 600 *Elamites* attacked *Lagash* in the time of his nephew *Entemena*. The country was conquered by *Sargon I* of *Agade*, and held by *Rimush*, *Manishtusu*, *Sargon II*, and *Naram-Sin*. *Gudea* of *Lagash* fought with *Anshan* in *Elam*, and used *Elamites* and *Susians* in the building of a temple. After the fall of the dynasty of *Akkad* and during the *Gutian* period, *Elam* was independent. To this time belong *King Basha Shushinak* and the dynasty founded by *Ebarti* and his son *Silhaha*. *Kudur-Nanchundi I* conquered *Babylonia* in 2285 B.C. *Simti Shilchak* was his successor. *Kudur Mabuk*, Prince of *Yamutbal*, an *Elamitic* principality between the *Pushti Kuh* and *Jebel Hamrin*, styles himself "father of *Martu*" (probably *Syria*). His son *Rim Sin* was vicergerent in *Larsam* until he was conquered by *Hammurapi* in the thirtieth year of his reign, or 2094 B.C. A *Kushite* chief, *Gandesh*, invaded *Babylonia* and founded a powerful dynasty there (1761-1185 B.C.). Inscriptions have been found of *Kurush*, King of the *Susian Anzan*, in 1155 B.C. *Kurush* of *Elam* fought with *Kurigalzu II* of *Babylon* (1333-1283 B.C.) and was taken captive at *Kar Dungi*. After this *Babylonian* conquest of *Susa*, *Inshushinak*, his son *Shatrak Nanchundi*, and grandson *Shilchak Shushinak* (c.1150 B.C.) seem to have reigned. *Nabukuduruzar I* (c.1160-1130 B.C.) and *Mar-duknadinachi* (c.1120-1105 B.C.) fought with *Kashi* and *Elam*, as did also *Samsi Adad II* (825-812 B.C.) and *Adadnirari III* (812-783 B.C.), who conquered *Ilip* (northeast part of *Elam*) and *Umlash* (between *Jebel Hamrin* and the *Euphrates*). Owing to the frequent references to *Elam* in the *Assyrian* inscriptions from the time of *Tiglath-pileser IV* (745-728 B.C.) to that of *Asurbanipal* (668-625 B.C.), it is possible to give an approximately correct list of kings with their dates for 100 years: *Chumbanigash* (742-717 B.C.), *Shutruk Nanchundi* (717-699 B.C.), *Challudash* (699-693 B.C.), *Kudur Nanchundi III* (693-692 B.C.), *Chumbami-*

nanu (692-689 B.C.), Chumbachaldash I (689-681 B.C.), Chumbachaldash II (681-675 B.C.), Urtaki (675-664 B.C.), Tammariu I (664-657 B.C.), Tiumman (657-655 B.C.), Tammariu and Chumbanigash (655-648 B.C.), Indabigash (648 B.C.), Chumbachaldash III (647 B.C.), Tammariu II and Chumbachaldash III (647-642 B.C.). The long struggle between Elam and Assyria, during which Sennacherib was humiliated in 694 B.C. by Challudash, who carried away his son Asurnadinshum from Babylon, and in 690 B.C. by Chumbaminanu, who probably won the battle of Chaluli, led to the imposition of Assyrian suzerainty in 655 B.C., and the final destruction of the state in 642 B.C., when Susa was razed to the ground, and 32 statues of kings and all the images of the gods were carried away to Nineveh. How long the Assyrians were able to maintain their power in Elam is not known. Jer. xlix. 35-39 cannot be quoted to show the condition in the time of Nebuchadnezzar, for this prophecy was probably written at the end of the Achaemenian period, and Elam stands for Persia. Media under Cyaxares and Astyages claimed suzerainty over Elam. But the Hatamti kings whose inscriptions have been found at Mal Amir seem to have been quite independent in the beginning of the sixth century, and the same is probably true of Teispes, Cyrus I, Cambyses I, and Cyrus II as kings of Anshan. In the Achaemenian period Elam was loyal to Cyrus, Cambyses, and Smerdis, rebelled against Darius, but remained a favored satrapy, whose capital was one of the residence cities of the kings. For the recent excavations in this city, see **SUSA**. See also **CUNEIFORM INSCRIPTIONS**.

ELAND (Dutch, elk, Ger. *Elend*, Lith. *ėlnis*, stag, Gk. ἑλός, *elos*, fawn). The largest of African antelopes (*Taurotragus oryx*). It is so bovine in general appearance that it was at once called elk by the Dutch pioneers of South Africa, and the males and females are yet spoken of as bull and cow. It is as large as a tall horse, well-grown examples reaching 6 feet in height, and weighing sometimes as much as 1500 pounds, though the average weight does not exceed 1000 pounds. The massive form is shown in the illustration on the Plate of ANTELOPES. The usual color is a bright rich fawn, with the hair short and smooth; but in age the bulls lose much hair so that the blue tint of the skin shows beneath it. A broad, deep-fringed dewlap reaches to the knee. The horns are very strong, rise straight upward, with considerable spreading, and are about 28 inches long in large bulls and a little longer, but more slender, in

the cows. The flesh is exceedingly good eating (except in the dry season), and the hide of much value for harness, etc.; moreover, their gentleness, weight, and consequently their comparative slowness, with their habit of moving in herds, make them a comparatively easy prey. Hence the elands were practically exterminated from South Africa by 1890, and those of Central Africa were nearly swept away by rinderpest a few years later. Very few are left even in the remotest districts. Many examples have been kept in captivity and found amenable to domestication. Native names were canna and impofo. In Western Equatorial Africa a second and considerably larger species, or subspecies (*Taurotragus derbianus*), still exists in large numbers. Consult Lydekker, *Game Animals of Africa* (London, 1908), and Roosevelt and Hellen, *Life-Histories of African Game Animals* (New York, 1914).

ELANSK, ye-lánsk'. See **YE-
LANSK**.

EL'APHURE

(from Gk. ἑλαφος, *elaphos*, stag + οὐρά, *oura*, tail). A book name for David's deer (*Cervus davidianus*) of northern China and Manchuria. It is frequently kept in parks by Chinese nobles and has been similarly

ANTLERS OF ELAPHURE.

kept alive in Europe, but in regard to its wild habits little is known. It is of the rucervine type, resembles in size and form the Indian swamp deer (q.v.), but has long shaggy hair. It is peculiar in having no brow tine to the antlers.

ELAPIDÆ (Neo-Lat. nom. pl., from Lat. *elaps*, *elops*, Gk. ἑλλοψ, *ellops*, sort of sea fish). A family of proteroglyph venomous terrestrial serpents, the coral snakes and their allies, with grooved fangs. Elapidæ of moderate size and great beauty are found in America (genus *Elaps*), in Africa (genus *Microsoma*), and in Australia (genus *Vermicella*). The American species inhabit the tropics, except three species in the southern United States. See **CORAL SNAKE**, and Colored Plate of **SNAKES**, FOREIGN VENOMOUS.

EL-ARABAH, ʔl-ā-rā-bā, WADI. A portion of the depression or "rift" valley which extends from the foot of Mount Hermon southward to the Gulf of Akabah, at the head of the Red Sea. It is one of the most remarkable depressions on the globe, being 682 feet below sea level at the Sea of Galilee and 1292 feet at the Dead Sea. About 6 miles south of the Dead Sea it is crossed by a line of chalk cliffs, and the valley north of this point is now named El-Ghōr. The southern part of the valley, which still bears the Hebrew name El-Arabah, is about 100 miles in length and from 3 to 12 miles in breadth. See **ARABAH**.

EL-ARASH, ʔl-ā-rish'. See **LARASH**.

EL-ARISH. An Egyptian city and fortress on the Mediterranean and on the Wadi el-Arish, which marks the Palestine frontier (Map: Egypt, C 1). It is the chief city of a territory bearing the same name. The city proper contains about 5000 inhabitants. About 13,000

nomads roam over the territory. In the Middle Ages the city was known as Laris. King Baldwin I of Jerusalem died there in 1118. The French under Kléber took it in 1799, but were obliged to abandon it the same year.

EL'ASIP'ODA. See HOLOTHURIAN.

ELASMOBRANCHII, é-las'mô-brān'ki-i (Neo-Lat. nom. pl., from Gk. *ελασμός*, *elasmos*, metal plate + *βράγχια*, *branchia*, gills), or CHONDROPTERYGII. A group of fishes whose skeleton consists of cartilage and connective tissue alone, there being no distinct bones present, comprising only the sharks, rays, and chimæras. The cranium is composed of a single piece, without sutures and separate parts as in the higher vertebrates. The skin is in nearly all cases provided with placoid scales. The males in the recent forms have the ventral fin modified into copulatory organs known as claspers. The caudal fin is heterocercal. The gill slits, five to seven in number, open directly to the exterior (except in the chimæras), and the gill filaments are fastened for their whole length to the interbranchial partitions. The intestine has a spiral valve, a fold of its wall into the interior arranged in a spiral fashion. No swimming bladder is present. The eggs are large and few in number and are fertilized inside the body of the mother, where in many cases they undergo development. The two main groups, viz., the Selachii, which comprises the sharks and rays, and the Holocephali, or chimæras, include, besides the many living, many extinct forms, our knowledge of which (the skeleton being cartilaginous and therefore not preserved) is derived from fossilized teeth and dermal scales. Fossil remains of the Selachii first appear in the Upper Silurian and throughout the Paleozoic times are very abundant. The Holocephali appear first in the Lower Jurassic, a few probable remains having been found in the Upper Silurian. It is among the elasmobranchs that we find the most primitive type of fishes. One of these more generalized primitive groups, the Cestracient (q.v.), abundant in Paleozoic times, is represented to-day by two or three species of Port Jackson sharks (q.v.). None of the elasmobranchs are very small, and among them are some of the largest of aquatic vertebrates. There are about 300 living species, all marine.

ELASMOSAURUS (Neo-Lat., from Gk. *ελασμός*, *elasmos*, metal plate + *σαῦρος*, *sauros*, lizard). A genus of the order Sauropterygia, one of the few American representatives of the European plesiosaurs. Remains of this sea serpent have been found in the Cretaceous deposits of New Jersey. It resembled the plesiosaurs in shape, but had a flattened tail. See PLESIOSAURUS; CRETACEOUS SYSTEM.

ELASMOTHERIUM (Neo-Lat., from Gk. *ελασμός*, *elasmos*, metal plate + *θηρίον*, *thērion*, wild beast). An extinct fossil rhinoceros of gigantic size, found in the Pleistocene deposits of Siberia and Russia. See RHINOCEROS.

ELASTICITY (from Gk. *ελαβεῖν*, *elaubein*, to drive, set in motion). A general property of matter (see MATTER) in virtue of which, if it is strained in any way by means of a force, it returns to its former condition more or less perfectly when the force is removed.

Solids. A solid body is distinguished by having under ordinary conditions a definite volume and shape, both of which may, however, be altered by the application of suitable forces. In general, when a solid is deformed in any way

—e.g., bent, stretched, etc.—any small portion of it has both its size and shape changed. To secure a strain of the solid such that each minute portion preserves its shape and suffers a change in volume only, it is necessary to apply a uniform pressure, i.e., a uniform force per square centimeter, over the whole surface of the solid, thus compressing it equally in all directions. This can be done by immersing the solid body in some liquid—e.g., water—which can be put under a great pressure. Let the original value of the volume be v and of the pressure be p ; then if, as the result of increasing the pressure by a small amount Δp , the volume is decreased a small amount Δv , the “coefficient of elasticity for a change in volume”—or the “bulk modulus”—is defined to be

$$k = \frac{\Delta p}{\frac{\Delta v}{v}}$$

The ratio $\frac{\Delta p}{v}$ is called the “strain”; and Δp , the change in the force per square centimeter, equals what is called the “stress.” Stress is the alteration in the pressure of the portions of the solid on each other; i.e., it is an *internal* property. It is measured, however, by the external force producing the deformation; because, when this force is applied, the body is compressed and there are forces of restitution produced which oppose the applied force and exactly balance it when there is no further compression. For any one substance, e.g., a definite kind of glass or iron, k is a constant quantity.

To produce a change in the shape of minute portions of a solid without sensibly altering their volumes, it is necessary to apply what is called a “shearing” stress, i.e., a combination of forces like that due to a pair of shears when used in cutting a piece of paper or cloth. Thus, if a cubical block of wood is held between two

boards firmly screwed to it, and if the boards are pushed slightly sidewise, but in *opposite* directions, the upper one to the right and the lower to the left, the block will have its shape changed to an oblique solid, as indicated in exaggerated form in the diagram, while the change in the volume will be infinitesimal. The angle through which the edge of the block is turned is taken as the measure of the strain; and the stress equals the force used to push one of the boards sidewise divided by the area of the cross section of the block. This stress is an internal force, being due to the reaction of the solid against the shearing forces which tend to make one layer of the solid move over the other. When there is no further alteration under the action of these external forces, they must be exactly equal and opposite to the internal forces of restitution. Calling this ratio of the force to the area T , and the angle of the strain I , the coefficient of elasticity for a change in shape—or the coefficient of rigidity—is defined as

$$n = \frac{T}{I}.$$

The simplest case in practice of a pure change in shape is when a wire or rod is twisted slightly round its axis of figure; this is called "torsion." It can be shown from theoretical considerations that if a wire or rod with a circular cross section is clamped at one end and the other end twisted around the axis through an angle Ψ , a moment will be required equal to

$$\frac{\pi r^4 n \psi}{2 l}$$

where r is the radius of cross section and l is the length of the wire. It is found that for any definite kind of matter, regardless of its size or shape, n is a constant quantity.

By far the commonest deformation of a solid is that experienced when a rod or beam is stretched, compressed, or bent. In all these cases it is evident that it is simply a matter of changing the length of the rod or beam, or of certain portions of it. Thus, if a wire of cross section A and of length L is clamped at one end and under the stretching force F is elongated by an amount l , the strain is defined to be l/L and the stress equals F/A . This stress, although measured by the applied force, is the internal reaction. The ratio of these two, viz.

$$E = \frac{F}{\frac{l}{L}} = \frac{FL}{Al},$$

is called "Young's modulus" because its importance was first emphasized by Thomas Young. In this deformation both the size and shape of the small parts of the wire are altered; and therefore Young's modulus must depend upon both the bulk modulus and the coefficient of rigidity. Calling Young's modulus E , it may be shown theoretically that

$$\frac{1}{E} = \frac{1}{9k} + \frac{1}{3n}.$$

Solids differ greatly in their compressibility and in their rigidity; and they differ widely in the extent to which they may be deformed and yet recover their former shape and size when released from the deforming forces. If the strain is too great, the body does not regain its former condition; the "limits of elasticity" are said to have been passed. A body is called "elastic" if these limits permit a large strain, e.g., glass, steel; while if these limits permit only small or minute strains, the body is said to be "inelastic." If, however, the strain is small enough, solids do return quite exactly to their former states; and for such small strains it is observed that the amount of the deformation produced varies directly as the deforming force. This is called "Hooke's law," from the name of the one who first proposed it, Robert Hooke. Many solids after being strained return to their previous condition slowly after the deforming force is removed; and nearly all take considerable time to reach their permanent strain when a force is applied. There is therefore a slight molecular "slipping" in general in every deformation of a solid; this necessarily involves internal friction and the production of heat effects—in particular, rise in temperature. A "perfect" solid might be defined as one in which there is no internal friction; while the more inelastic a body is, the greater are the

slipping and the internal friction when there is a deformation.

Since solids have, in general, elasticity both as to change in volume and as to change in shape, a solid medium can transmit two kinds of waves, compressional and transverse. (See WAVES.) A solid rod, too, can vibrate in several ways: longitudinally, if it is stroked lengthwise; torsionally, if it is twisted; from side to side, like a tuning fork, if it is bent.

Fluids. A fluid is defined to be such a form of matter as will yield to a shearing force, however small. Thus, it is necessary to discuss the elasticity of fluids with reference to changes in volume only. As before, the definition of the coefficient of elasticity is

$$k = \frac{\Delta p}{\frac{\Delta v}{v}},$$

where v is the original volume and Δv is the decrease in the volume accompanying an increase in the internal pressure of an amount Δp . For liquids k is very large, since they are so slightly compressible; for a gas, however, it is much smaller. When any portion of matter is compressed, the temperature is increased (except in most special cases); and this fact alters the value of the change of pressure corresponding to a definite change in volume. If the change in volume is to be due to the change in pressure alone, it is necessary to change the volume so slowly that the temperature remains practically constant. This fact is of particular importance in the case of gases, because they are so easily compressed and there is accordingly such a great rise in temperature unless care is taken. If the gas is compressed so suddenly that the whole change in volume takes place before there is time for any loss of heat by radiation or conduction, the temperature will rise greatly, and this will produce a marked increase in the pressure of the gas, thus increasing the coefficient of elasticity for the gas.

The coefficient for a gas, when there is no change in temperature, may be calculated from Boyle's law, which states that as long as the temperature of a gas does not change, the product of its pressure and volume remains constant, however the volume is altered. Thus, if v is the volume of the gas when the pressure is p , and $v - \Delta v$, the volume when the pressure is increased to $p + \Delta p$, then $p v = (p + \Delta p)(v - \Delta v) = p v - p \Delta v + v \Delta p$, if Δp and Δv are so small that their product may be neglected. Hence $p \Delta v = v \Delta p$ and therefore

$$k = \frac{\Delta p}{\frac{\Delta v}{v}} = p.$$

In words, the coefficient of elasticity for a gas at constant temperature numerically equals its pressure. If, however, the change in volume is made so rapidly that the heat has no time to escape, the coefficient is γp , where γ is a constant for any one gas, being equal to the ratio of the specific heat at constant pressure to that at constant volume. (See HEAT.) For air, hydrogen, and oxygen γ very nearly equals 1.4.

A fluid medium can transmit compressional waves only; and in these the vibrations must be rapid, otherwise the fluid would flow round the

vibrating body which is the cause of the waves. Therefore, the elasticity which is called into play is the one corresponding to no escape of heat.

Consult: Love, *Treatise on the Mathematical Theory of Elasticity* (Cambridge, Eng., 1906); Searle, *Experimental Elasticity* (New York, 1908); Lamb, *Statics, Including Hydrostatics and the Elements of the Theory of Elasticity* (New York, 1912).

ELASTIC LIMIT. See STRENGTH OF MATERIALS.

ELASTIC TISSUE. One of the forms of fibrous tissue, known also as yellow fibrous tissue. It derives its name from the remarkable physical property which it possesses of permitting its fibres to be drawn out to double their length, and again returning to their original length. It occurs in various ligamentous and other structures of the animal body in which elasticity is required, as in the vocal cords, the membranes connecting the cartilaginous rings of the trachea, the middle coat of the arteries, the skin, etc.

ELASTIN (from *elastic*). A characteristic chemical constituent of the substance of all elastic fibres of the animal body. It may be prepared from the ligamentum nuchæ of an ox by boiling with water, next heating with weak caustic potash solution, and further with dilute acetic acid; the substance thus obtained is treated with cold dilute hydrochloric acid, then boiled with strong alcohol, and finally subjected to prolonged and careful treatment with ether. In this manner gelatin, mucin, fats, etc., are removed from the tissue, the elastin remaining behind in the form of a yellowish powder which is elastic when moist, but becomes brittle on drying. By the action of strong hydrochloric acid and chloride of zinc, elastin is converted into several substances, including a small quantity of tyrosin and glycocoll; gelatin, if subjected to similar treatment, yields no tyrosin, while the true proteids yield no glycocoll and do yield glutamic and aspartic acids, which are not produced in the treatment of elastin. By means of the reaction just mentioned, elastin can, therefore, be readily distinguished from gelatin and the proteids. On the other hand, elastin may be distinguished from keratin by the action of pepsin or trypsin, which readily dissolve elastin, while they have no effect on keratin.

EL'ATE'A. See CITHÆRON.

EL'ATER (Neo-Lat., from Gk. *ἐλατήρ*, *elater*, driver, from *ἐλαίνειν*, *elaunein*, to drive). In plants, a peculiarly modified cell developed in great numbers in the spore cases of certain liverworts, as *Marchantia*. The cells occur among the spores, and have the form of elongated fibres,

with spiral thickened bands. When the spore case bursts, the elaters ("jumpers") bend and straighten by jerking motions and help to

ELATERS:

1, of a liverwort; 2, of *Equisetum*.

loosen up the mass of spores, which are scattered by currents of air. The name elater is also applied to the hygroscopic spiral bands on the spores of *Equisetum*. See HEPATICÆ; EQUESETUM.

EL'ATERIDÆ

(Neo-Lat. nom. pl., from Gk. *ἐλατήρ*, *elater*, driver). A large family of beetles, commonly known as elaters or click beetles. About 7000 species are described, of which over 500 occur in the United States. The most conspicuous North American one is the eyed elater (*Alaus oculatus*), which has two large velvety spots on the prothorax. See CLICK BEETLE; WIREWORM.

AN ELATER.

Adult beetle and larva — a wireworm (w).

ELATERIN (from *elaterium*), $\text{C}_{20}\text{H}_{25}\text{O}_5$. A neutral principle contained in elaterium (q.v.), from which it may be prepared by exhausting with chloroform, precipitating the resulting solution with ether, and purifying the precipitate by recrystallization from chloroform. Elaterin is a permanent white substance crystallizing in the form of small hexagonal scales, or in the form of prisms. It has no odor, but has a bitter, slightly acid taste. It is sparingly soluble in alcohol and in ether, and is practically insoluble in water. The triturate of elaterin is an official preparation, and is the most powerful hydragogue purgative known. It may be used, with great caution, in Bright's disease and in ascites. See ELATERIUM.

ELATERITE. A soft, elastic variety of asphalt resembling India rubber. It is subtranslucent, has a brownish color and a specific gravity varying from 0.9 to 1.0. It is found in Derbyshire and elsewhere in England and is of no commercial value.

EL'ATERIUM (Neo-Lat., from Gk. *ἐλατήριος*, *elaterios*, driving, from *ἐλατήρ*, *elater*, driver, from *ἐλαίνειν*, *elaunein*, to drive). A substance obtained from the fruit of the squirting cucumber (*Ecballium elaterium*), also called the wild cucumber. The plant is an annual of the order Cucurbitacæ, a native of the south of Europe, common on rubbish in the villages of Greece and the Archipelago. The whole plant is rough, with stiff hairs; it has a trailing, branching stem, without tendrils; the leaves are heart-shaped,

somewhat lobed and toothed, on long stalks; the flowers axillary, yellow, the male flowers in small racemes; the fruit oblong, about an inch and a half long, grayish green, covered with soft prickles, and finally parting from its stalk, and expelling its seeds along with a thin mucus through the aperture where the stalk was inserted. It is this mucus surrounding the seeds—a thick green mucus of a very peculiar character—which contains the elaterium. To obtain the latter, the juice of the nearly ripened fruit is allowed to stand for a short time, when it becomes turbid and deposits a sediment. The sediment, carefully collected and dried, is elaterium. It is of a pale grayish-green color, light and friable, with an acrid taste and a peculiar, not unpleasant odor. It is the most powerful hydragogue cathartic in the pharmacopœia. The drug is likewise depressant and should be given with extreme caution. Its purgative action seems to depend chiefly on a principle called elaterin (q.v.).

ELATH. The modern Akabah (q.v.), a seaport situated in the extreme south of Idumæa, at the head of the Gulf of Akabah (Map: Egypt, C 2). t. ii. 8, it was one of the stations on the route from Egypt. It is probably a later designation of El-Paran (Gen. xiv. 6) and the same as Elah (Gen. xxxvi. 41). Other variant forms are Eloth and Elim. David captured it from the Edomites (2 Sam. vii. 14), and under Solomon it became an important naval station (1 Kings ix. 26). Edom recovered its independence in the days of Jehoram, but subsequently Elath passed once more into the possession of Judah (2 Kings xiv. 22); again in 734 B.C., in the days of Ahaz, it passed out of the hands of Judah, and this time permanently (2 Kings xvi. 6). Later it belonged to the Edomites, the Nabatæans, and the Romans. In the days of Eusebius Elath was a town of commercial importance and carried on trade with such remote places as India. The old Aila, or Elath, was in the ninth century, and the new city Waila became a centre of civilization. The Crusaders conquered the place in 1116. Saladin and captured it in 1171. Renaud de attacked it with a fleet in 1181 and in part destroyed the city. It is usually called simply Akabah, and belongs to Hejaz, but is connected with Maan by telegraph. There are some heaps of ruins representing the ancient Aila about one mile north of the place. See Musil, *Arabia Petraea II Edom* (Vienna, 1908).

ELBA (Gk. Αἰθάλεια, *Aithaleia*, Lat. *Ilva*). A mountainous, unwooded island of the Mediterranean, the largest of the Tyrrhenian archipelago, attached to the Tuscan Province of Leghorn, Italy, 5½ miles southwest of Piombino (q.v.) (Map: Italy, E 5). It is 18 miles long, from 3 to 10 broad, and has an area of 86 square miles, forming part of a sunken mountain range that extends from the Italian mainland to Corsica and Sardinia. The highest point is Mount Capanne, 3350 feet. The climate is mild and healthful and the soil is fertile, but farming is neglected because of rich mineral deposits. From ancient times Elba has been famous for its iron ore, as is indicated by the name of the capital, Porto Ferrajo (iron port). Most of the inhabitants of the island (pop., 1901, 25,043; 1911, 30,150) are employed in the iron industry. Other mineral products are copper, tin, lead, marble, granite, sandstone,

and salt. Tunny and sardine fishing and the extraction of sea salt are other important industries. Elba is chiefly known as the residence of Napoleon after his first abdication, from May 4, 1814, to Feb. 26, 1815, when he escaped and returned to France, landing at Cannes, March 1. He enjoyed full sovereignty over the island, with the title of Emperor and an income of 2,000,000 francs a year. During his stay he had the road built Porto Longone with Porto Ferrajo. San Martino that he occupied still stands in Porto Ferrajo between the forts Stella and Falcone, erected by Cosimo I, Duke of Florence. In it is the Egyptian hall with the inscription "Ubique Felix Napoleon." In the Middle Ages Elba was subject in turn to Pisa, Genoa, Sora, and Piombino. After Napoleon departed the island was restored to Tuscany, which became part of Italy in 1860. Consult L. Simonin, *La Toscana et la mer* Paris, 1868), and Fatichi, *Isola* 1885).

ELBASSAN, ěl-bās-sān'. A town in Albania on the Scumbi, 35 miles east of the mouth of the river (Map: Turkey in Europe, C 4). It stands in a fertile plain surrounded by mountains, and is the seat of a Greek bishopric. There are a number of hot sulphur springs in the vicinity. It has manufactures of iron and copper wares. Pop. (est.), 15,000.

ELBE, ěl-be (dialectic *Albe*, OHG. *Elba*, *Alba*, from OHG. *elf*, Icel. *elfr*, river; called by the Romans *Albis*, by popular confusion with *albus*, white, and by the Bohemians *Labe*). An important river of central Europe, ter communication from Austria and of Germany to the port of Hamburg (Map: Germany, D 2). It originates in the confluence of numerous streams which rise at the southwestern base of the Schneekoppe, one of the highest summits of the a mountain range on the northeast border of Bohemia. Beginning near lat. 50° 45' N. at an elevation of 4400 feet above sea level, it has a total length of about 725 miles, of which about 525 miles are navigable. Its basin is estimated at 56,500 square miles. Through most of its course the Elbe is less than 1000 feet wide, but at its long estuary-like mouth it has a width of several miles. From the base of the Schneekoppe it flows south to Pardubitz, thence west to Kolin, and then in a generally northwesterly direction past Melnik, where it is 425 feet wide and becomes navigable for small boats. At Tetschen it leaves Bohemian territory, breaking through the Mittelgebirge and then the Erzgebirge at the only point in the Bohemian frontier below 1500 feet, and enters Saxony. Its principal affluent in Bohemia is the Moldau.

On its way northwest through Saxony the Elbe passes Pirna (where it becomes navigable for quite large boats), Dresden, and Meissen. Entering Prussian Saxony, it passes Wittenberg, from which point it flows first west, then northwest to Magdeburg (where it has a width of 800 feet), having received the Mulde and the Saale, both from the south. From Magdeburg flowing northeast the Elbe arrives at the border of Brandenburg, receiving the Havel from the southeast. Turning northwest, it enters Hanover, through which it flows for about 30 miles. Then, still couring northwest and past Hamburg and Altona, the Elbe empties into the North Sea at Cuxhaven, where it attains a breadth of about 10 miles, and where the tide

rises 13 feet. Numerous islands divide the Elbe into several branches between Hamburg and the north and Harburg on the Elbe. Steamship liners ascend to Hamburg, 60 miles from the sea. Navigation on the Elbe has been greatly improved by the application of modern methods. The river has been canalized for a distance of about 75 miles, dams constructed to deepen the channel, but in form in which they may be dropped flat at the bottom of the river in case of flood or frost, locks constructed, and conditions so improved that vessels of 800 tons are now used where only those of 250 tons could formerly operate. A "towing chain" has been laid at the bottom of the river from Hamburg to Aussig, Bohemia, a distance of over 100 miles. The chain, which is stationary in the bed of the river, passes over a revolving wheel or drum on the vessel, by which large barges loaded with merchandise are moved from Hamburg to the heart of Bohemia. A series of canals also connects the Elbe with the Oder, the Spree, and the Trave, the cost of the Elbe-Trave canal, 45 miles long, having been nearly 6 million dollars, borne chiefly by the Kingdom of Prussia and the state of Lubeck. The towns and cities along the 525 miles in which the river is navigable have expended large sums in the construction of harbors, wharves, docks, warehouses, and other facilities for the encouragement of commerce, and the volume of merchandise now moved on the Elbe is many times that prior to the adoption of the improvements above noted, and exceeds that of any other river of Germany. The scenery of the valley of the Elbe, though generally pleasing, is not remarkable in any portion of its course except that between Aussig and Dresden. Here the high, steep, rocky cliffs and other beautiful scenery have given the district the name of "Elbschönland." The Elbe is stocked with fine fish. Its commerce is very extensive and important. Consult: Semmler and Münnig, *Der Elbstrom von seinem Ursprung bis zu seiner Mündung* (Dresden, 1845); Bose, *Allgemeine geographische und hydrotechnische Beschreibung der Elbe* (Annaburg, 1852); Nehls and Bubenberg, *Die Elbe* (Hamburg, 1852); Zander, *Die Bedeutung der Elbe für den Handel Sachsens* (Chemnitz, 1891); Lohse, *Die Niederelbe*, 4th ed. (Leipzig, 1913).

ELBE, AUGUSTE VON DER. See DECKEN, AUGUSTE VON DER.

ELBÉE, *el'bā'*, MAURICE LOUIS JOSEPH GIGOT D' (1752-94). A Vendean general. He was born at Dresden and was of remote Scottish extraction. Upon the outbreak of the Revolution he was elected to the Constituent Assembly, but emigrated in 1791. He returned in 1792, and after the death of Cathelineau was proclaimed commander in chief of the "Catholic and Royalist army." After winning a succession of brilliant battles he was captured by General Thureau, condemned to death by a council of war, and shot.

ELBERFELD, *el'ber-fēlt*. One of the most important manufacturing towns in Germany, situated on both sides of the Wupper, an affluent of the Rhine, in the Prussian Rhine Province, 16 miles east-northeast of Düsseldorf (Map: Germany, B 3). With the sister city of Barmen, which adjoins, it forms a single industrial centre of 325,000. The old parts of the town are poorly built, their streets are irregular, but the

more recently erected portion is thoroughly modern, with broad streets and imposing buildings. The Rathaus, the courthouse, many public squares with handsome monuments make the newer city attractive. Elberfeld is one of the centres of the textile industry. It has numerous establishments for the dyeing, weaving, and printing of cotton, silk, woolen, and mixed goods, and also manufactures of furniture, dyes, chemicals, iron and steel products, paper, carpets, beer, arms, leather, rubber goods, gold and silver ware, machinery, wall paper, and stained glass. Most of its textile industries date from the eighteenth century. The commerce of the town is extensive and there are a number of financial institutions and consular agents from many foreign countries. The educational institutions of the city include a gymnasium, a mechanics and polytechnic school, an industrial drawing school, and an institute of music. The city is noted for its poor-relief system, and is the headquarters of the Berg Bible Society. Elberfeld is an important railway centre and has seven stations. Electric street railway lines traverse the town and connect it with Barmen, while a suspended electric road follows the bed of the Wupper from Rittenshausen to Sonnborn. Eighteen bridges are thrown across the river to facilitate the immense traffic. Pop., 1900, 157,927; 1910, 170,195. Elberfeld is situated about a castle belonging to the Duke of Berg. Elberfeld, erected in the twelfth century, but was afterwards united with the Duchy of Berg. It obtained municipal privileges in 1610. Industrial prosperity began in the latter part of the eighteenth century through the introduction of silk weaving and Turkey-red dyeing. In 1815 it passed with Berg to Prussia. Consult: Schnell, *Geschichte der Stadt Elberfeld* (Elberfeld, 1900); A. Shadwell, *Industrial Efficiency* (London, 1906); Jorde, *Führer durch Elberfeld und seine Umgebung* (Elberfeld, 1902).

ELBERFELD SYSTEM. The manufacturing town of Elberfeld, Prussia, has become famous for its plan of relieving the poor. The reform began in 1800, when, dissatisfied with existing conditions, the city appointed six visitors to investigate applications for relief. The visitors were increased to 12 the following year. In 1802 there was a great increase. The city was divided into eight districts and these districts into four sections, and a board of supervisors chosen. The system was further extended in 1841. In 1850, dissatisfaction having arisen in several quarters, the Lutheran church attempted to do the work. Matters were not improved. In 1852 the present plan was proposed by a banker, Daniel von Heydt, and was put in operation. The city was divided into 364 precincts, and over each was placed an unsalaried almoner whose duty was to investigate each applicant for aid and to make visits every two weeks as long as aid was given. Fourteen precincts form a district. The almoners meet every two weeks under direction of an unpaid overseer to discuss the cases and to vote needed relief. These proceedings are reported to the directors, comprising the mayor as ex-officio chairman, four councilmen, and four citizens (also unpaid), who meet the day following and review and supervise the work throughout the city. In emergency cases the almoner may furnish assistance. Relief is granted in money according to a fixed schedule for two weeks at a time,

any earning the family may have being deducted. Tools are furnished when advisable. The system has given great satisfaction; the expenses in proportion to the population have gradually decreased, and the condition of the poor is said to have improved. The essential principles of the Elberfeld system have found application in the public-relief administration of the cities of the Rhineland, notably in Cologne, Crefeld, Düsseldorf, Aix-la-Chapelle, and Remscheid. A similar system has been employed in Hamburg since 1788; in 1792 the Hamburg plan was reorganized under Elberfeld influence. The same influence has been potent in the reorganization of relief systems in most of the German cities. Attempts to introduce the system in non-German cities have not met with marked success. See CHARITY ORGANIZATION SOCIETY; PAUPERISM.

ELBERTON. A city and the county seat of Elbert Co., Ga., 34 miles east by north of Athens, on the Seaboard Air Line and the Southern railroads (Map: Georgia, D 1). The city contains a public library and owns the water works and electric-lighting plant. It is in a cotton-growing region, and has a cotton factory, a cotton compress, a cottonseed-oil mill, fertilizer factories, harness, carriage and wagon shops, ironworks, granite quarries, etc. Pop., 1900, 3834; 1910, 6483.

ELBEUF, *él-béf'* (Lat. *Elborium*). A modern town in the Department of Seine-et-Marne, in a valley on the left bank of the Seine, 14 miles by rail from Rouen (Map: France, N, F 3). The two principal buildings are the churches of Saint-Etienne and Saint-Jean-Baptiste, both containing fine specimens of richly painted glass of the fourteenth and fifteenth centuries. It has schools of instruction in cloth manufacture and industry. There are numerous factories in Elbeuf and the suburban communes of Saint-Pierre-les-Elbeuf, Caudebec-les-Elbeuf, Orival, and Saint-Aubin-Jouxte-Boulogne, principally of double-twilled and waterproof cotton-linen fabrics, and light woolens of every color and description, which employ fully half of its inhabitants. Pop., 1906, 17,800; 1911, 18,290. Elbeuf had 80 cloth manufacturing factories as early as the sixteenth century, but when the Edict of Nantes was revoked the greater number of the cloth makers emigrated and it was not till after the revolution of 1789, and later the separation of Belgium and France, that the industry revived.

ELBING, *él'bing*. An important commercial town in the Prussian Province of West-Prussia, on the navigable Elbing, about 5 miles from its mouth in the Frisches Haff, and 35 miles east-southeast of Danzig (Map: Prussia, H 1). It is connected by a canal with the Nogat, the eastern arm of the Vistula. The town was formerly surrounded by a wall, of which, however, but few traces remain. Among its manufactures are machinery, linen and cotton cloths, leather, tobacco, soap, chicory, lumber, flax and hemp yarn, as well as trade in agricultural products. There are also oil manufactories, iron foundries, dye and print works, and the famous Schichau shipbuilding works for the construction of war vessels. Elbing has excellent railway facilities and is in steamboat communication with Danzig and Königsberg. Pop., 1900, 52,518; 1910, 58,636. It was founded about the beginning of the thirteenth century by colonists from Lübeck and Bremen, who settled about the fortress erected by the Knights

of the Teutonic Order. It early joined the Hanseatic League, but in 1454 came under Polish rule. It suffered severely from religious strife among its citizens and from the wars of Sweden, Poland, and Russia. In the first partition of Poland it was annexed to Prussia in 1772, and, after a period of decline, has again risen to a thriving condition.

EL-BOSTAN. See ALBISTAN.

ELBOW. See ARM.

ELBOW-PIECES, *COUDIÈRES*, or *COUDES* (Fr.). In mediæval armor, the metal plates used to cover the junction of the brassards and vambrace, by which the upper half and lower half of the arm were covered. They were of three principal kinds, disk-formed, cup-formed, and articulated, and were sometimes armed with spikes. In the fifteenth century they were sometimes fan-shaped and of enormous size. Consult Ashdown, *Arms and Armour* (New York, 1909).

ELBRUZ, *él-brōōz'*. The highest summit of the Caucasus Mountains (q.v.), and the loftiest peak in Europe (Map: Russia, F 6). It is situated in lat. 43° 21' N. and long. 42° 25' E. It is an extinct volcano with two craters, the mountain mass being composed of volcano rocks. Its elevation is 18,470 feet above sea level.

ELBURZ, *él-bōōrz'*. A mountain range in northern Persia, extending from the boundary of Persia and the Russian Province of Transcaucasia southeastward along the shores of the Caspian Sea, changing its trend near the southern limit of the latter to northeast towards the frontier of Turkestan (Map: Persia, D 3). The range marks the limit of the Iranian Plateau towards the Caspian depression and is a unit in the great mountain system that stretches from southern Europe eastward into Central Asia. The north slopes of the Elburz, receiving an abundant rainfall, are intersected by fertile valleys that support a rich tropical vegetation, while the south slopes are generally dry and almost barren. A single river, the Kura, crosses the range to enter the Caspian Sea. There are several passes, of which the most important are those connecting Teheran with Amol and Balfush, near the centre of the range, and, farther westward, that between Kasbin and Resht. The Elburz has an average altitude of about 5000 feet, the highest peak being Demavend with an estimated elevation of 19,000 feet.

EL CANEY, *él ká'ná*. A town of Cuba, 4 miles from Santiago de Cuba (Map: Cuba, K 6). Here on July 1, 1898, during the Spanish-American War, occurred the battle of El Caney, in which about 520 Spaniards, under General Vara del Rey, and about 1,000 Americans, under General Lawton. The Spaniards made a desperate resistance, but were finally overcome by the American infantry. The Americans lost 443 in killed and wounded and missing, the Spaniards 420 (including 100 prisoners). Consult: Lee, "The Regulars at El Caney," in *Scribner's Magazine*, vol. xxiv (New York, 1898); Norris, "Battle of El Caney," in *The Century* (ib., 1899); Bonal, "Battle of El Caney," in *McClure's*, vol. xii (ib., 1899).

ELCANO, *JUAN SEBASTIAN DE*. See CANO, *JUAN SEBASTIAN DEL*.

ELCESAITES, *él-sés'á-its*. See ELKESAITES.

ELCHE, *él'chá*. A town in the Province of Alicante, Spain, 16 miles southwest of the city of Alicante, on the river Vinalapo, about 2 leagues from the sea, and on the Alicante-Mur-

cia Railway (Map: Spain, E 3). The town is strikingly Oriental in appearance; its architecture in general has retained much of the Moorish character. Elche is well built and has several public squares, while it is partly surrounded by groves of date palms. The church of Santa Maria is an . . . e with a large dome and a tabern . . . marbles. Other important structures are the Casa Consistorial, bishop's palace, the hospital, and barracks. The dates gathered from the palm plantation are exported in considerable quantities; also the palm branches, which are used for religious purposes. Pomegranates are extensively cultivated and constitute another important article of commerce. The chief manufactures include woollens, articles of esparto grass, brandy, wine, oil, soap, leather, etc. Pop. (commune), 1900, 27,430; 1910, 30,713. Elche, anciently called Ilici or Ilici, was raised by the Romans to the dignity of a colony with the *jus Italicum*. It increased in importance under the Goths, as evidenced by its erection into an episcopal see, which, however, ended with the Moslem occupation. Excavations have brought to light objects of considerable archaeological interest. Of these perhaps the most exquisite piece is the terracotta bust of a Roman lady, now on exhibition in the Louvre.

An interesting fête occurs at Elche each summer from the 13th to the 15th of August and is well worth visiting despite the heat. These days are the fête of the Assumption, and are celebrated by Elche with a performance of the *Representation of the Assumption of Our Lady St. Mary*, a fourteenth-century liturgical, musical drama. The play is popularly known as the *Festa* (or *Misterio*) *de Elche*, but its real title is *Consuetudine de la Festa de Nostra Señora de la Asumptio que es celebra en dos Actes, Vespra y Dia, en la insigne villa de Elig, Escrita per un devot seu en VI dias del mes de febrer del año MDCXXXIX*. In its present form it is a seventeenth-century remodeling of a fourteenth-century Catalan drama on the same subject: *La representacio de la Asumpcio de Madoña Sta. Maria*. As the theatre or stage for the performance is the whole city, we naturally compare it with the *Festspiel* of Rothenburg, *Der Meistertrunk*. But as it has a religious topic, one must compare it also, *mutatis mutandis*, with the *Passion Play* of Oberammergau. For the original play, consult the edition by John Pie, published in the *Revista de la Comisión artística-arqueológica barcelonesa* (Barcelona, 1898), and reprinted, with another play, as *Autos sacramentales del siglo XIV* (ib., 1898), and the edition by the scholarly composer and musician Felipe Pedrell in the *Sammelbande der Internationalen Musik-Gesellschaft* (Leipzig, Jan.-March, 1910), which is the best edition and has a careful study of the sources and the musical score. For a sympathetic account of the whole festival, see Pierre Paris, "Les fêtes de l'Assomption à Elche (Espagne)," in *Le Correspondant*, vol 192, N. S., p. 156 (1898).

ELCHINGEN, ɛl'kɪŋ-en. A village of Bavaria near the left bank of the Danube, about 5 miles northeast of Ulm. It is noteworthy as the scene of a battle fought on Oct. 14, 1805, between the French, under Ney, and the Austrians, under Laudon, which resulted in the defeat of the latter and the surrender of Ulm. Ney's victory obtained for him the title of Duc d'Elchingen.

ELCHO, LORD. See WEMYSS, ninth EARL OF. **EL'DAD AND ME'DAD**. 1. Two persons mentioned in Num. xi. 26-29 as prophesying, though not present with Moses and the 70 elders at the tent of the meeting when Yahwe gave His spirit. Joshua is said to have demanded that they be forbidden. But Moses himself is credited with a wish that all Yahwe's people were prophets. The story is held to belong to a late stratum of the Pentateuchal narratives and to reflect a tendency to look with more generous sympathy upon men of the spirit condemned as false prophets in leading Ephraimite circles, as is suggested by the hostile attitude ascribed to Joshua. The name of the second prophet is given as Modad by the Greek version. Both names are . . . with Dad, who may be identical . . . In that case the . . . ld probably be

"Hadad is my . . . of Hadad," i.e., "Seed" or "Offspring of Hadad." Targum Jonathan to Num. xi. 26 et seq. makes these prophets predict the death of Moses, the succession of Joshua to the leadership, the coming of the King of Magog, the victory over him, and the resurrection of Israel to take part in the meal when the bull Leviathan is to be served. The Fragment Targum makes Eldad and Medad prophesy the destruction of Gog and Magog through Messiah, the King.

2. An apocalyptic work ascribed to Eldad and Medad is quoted in the *Shepherd of Hermas*, Vis. ii, 3, 4. The quotation reads, "Near is the Lord to those who return." As Targum Jonathan quotes a similar expression of the two prophets, "Near is the Lord to those that are in the hour of need," it is not impossible that the author was familiar with the same work. In his *Chronographia Compendiaria*, Nicephorus gives a list of canonical and apocryphal books which contains this work and states that it has 400 stichi. This list is found also in the . . . to Athanasius. Lightfoot . . . ink that the quotations in 1 Clem. xxii, 3, 4, and 2 Clem. xi, 2, have been drawn from the same source. Consult: Fabricius, *Codex Pseudepigraphus Veteris Testamenti* (Hamburg, 1722); Holtzmann, *Einführung in das Neue Testament* (Freiburg, 1892); Harnack, *Geschichte der altchristlichen Litteratur* (Leipzig, 1893); Zahn, *Geschichte des newtestamentlichen Kanons* (ib., 1890-92); Schürer, *Geschichte des jüdischen Volkes* (4th ed., ib., 1909); Funk, *Patres Apostolici* (Tübingen, 1901); Beer, "Eldad und Medad im Pseudojonathan," in *Monatschrift für Geschichte und Wissenschaft* . . . 1857, pp. 346 ff.; Bardenheuer, . . . altkirchlichen Litteratur I (Freiburg, 1913).

ELDAD HA-DANI, hæ-dä'nê, . . . century). A Jewish traveler, who undertook two voyages for the purpose of tracing the history of the Lost Ten Tribes of Israel. He had many extraordinary adventures, which are recounted in a narrative afterward translated into several languages, including English (1855). But the account is so highly fabulous that it is impossible to tell what parts are true.

EL'DER (AS. *ealdor*, *aldor*, comp. of *eald*, *ald*, OHG., Ger. *alt*, old; connected with Goth. *alan*, Icel. *ala*, Lat. *alere*, to nourish, as an ecclesiastical title an exact translation of the Greek *πρεσβύτερος*, *presbyteros*, comparative of *πρεσβύς*, *presbys*, old, which occurs frequently in the New

Testament). The title of an office bearer in certain churches. 1. In the Old Testament it is a title indicating in the earlier history the influence, dignity, and authority in their local community. In the Hebrew polity, as shown in the New Testament, the elders are the lay element in the Sanhedrin. It was a survival of the common early patriarchal system. 2. In the New Testament elder is also the title of certain officers in the newly organized society of Christians, corresponding to the rulers in the Jewish synagogues, who apparently exercised a considerable control in the conduct of the local churches. The office of elder developed very generally in the churches of the Reformation. In most of the churches on the continent of Europe which have any kind of connection with the state there is some regulation of the civil law with reference to the election and functions of elders. In some churches elders are appointed for a certain term of office; but more generally it is until death, resignation, removal from the bounds of the congregation, or deposition. The ordination of elders takes place in the congregation, but usually without the imposition of hands. In the Baptist churches the pastors of churches were formerly often called elders, although the term was specially applied to evangelists and missionaries. In the churches of the Presbyterian order the pastor of a church is technically called the *teaching elder*, as distinguished from the *ruling elders*, commonly called simply *elders*, who are a body of laymen varying in number, selected to assist the pastor in the oversight and government of the church. The board of ruling elders constitute with the pastor the session of the church and are intrusted with its government and discipline, subject to the supervision of the presbytery. Such elders are required to accept the symbol or confession of faith of the Presbyterian church; they do not administer the Sacrament, but may aid in the Lord's Supper by distributing the elements. They are sometimes elected for life, sometimes only for a term of years. In the Reformed churches (Dutch and German) the consistories include the ministers, elders, and deacons, and the latter two classes of officers are elected only for a term, with permission of reelection. In the early days of American Congregationalism many churches had in addition to a pastor and teacher a ruling elder charged with matters of church government and discipline. In the Methodist Episcopal church the presiding elder is an ordained clergyman appointed by and serving under the bishop, with large supervisory powers within a specified district. He presides over the quarterly and district conferences and visits the churches. Traveling elders are itinerant officers appointed by the annual conference. In the Methodist church the elder is an officer whose duty it is "to preach and baptize; to ordain other elders, and also priests, teachers, and deacons, to lay on hands for the gift of the Holy Ghost, to bless children, and to take the lead at all meetings." These elders constitute the Melchizedek priesthood, and include the apostles, the seventy, the patriarchs, and the high priest. Among the Shakers four elders, two males and two females, have charge of each of the aggregated families.

ELDER (OE. *elder*, *eller*, AS. *ellen*, *elder-tree*). A tree or shrub of the genus *Sambucus*, which belongs to the family Caprifoliaceæ.

There are about 20 widely distributed species. The common elder of Europe (*Sambucus nigra*) is a large shrub or sometimes a small tree, with large compound leaves and dense cymes of cream-colored flowers. The berries are black, occasional sports bearing white berries, which have a subacid, sweetish, and, to many, an unpleasant taste. They are extensively made into wine and used to adulterate port wine. The wood is yellow; that of old trees is hard, tough, takes a fine polish, and is used as a substitute for boxwood. The young wood has a very large pith. The scarlet-fruited elder (*Sambucus racemosa*) is a native of the colder portions of the Northern Hemisphere. It resembles the common species except in having greenish-white flowers and scarlet berries. This species is very ornamental and is frequently planted in shrubberies. The dwarf elder or danewort (*Sambucus ebulus*) is a peculiar species occurring in Europe, northern Africa, and western Asia. In the United States the common elder (*Sambucus canadensis*) is a species greatly resembling the *Sambucus nigra* of Europe. The cymes of the flowers are flat-topped, and the berries, which are purplish black, are used for making wine and occasionally other preparations. This species is a very common shrub along roads and fences. The scarlet-fruited species occurs in rocky situations and seems to fruit most abundantly at the north or where the climate is cool. *Sambucus mexicana*, of the southwestern United States and Mexico, is a tree attaining a height of 25 feet or more, with a trunk 12 to 15 inches in diameter. It branches abundantly and makes a dense shade. Medicinal properties have been attributed to the bark and the leaves, and hydrocyanic acid has been found in the leaves, young shoots, and green berries. The dried flowers are used in medicine. They contain a volatile oil, resin, wax, tannin, pectin, etc., and possess stimulant, carminative, and diaphoretic properties. The fresh fruits are used in the home manufacture of a wine, and elder-flower water is a common preparation used in confectionery. A perfume is made by distilling water, elder flowers, and rectified spirits. The proportions used are 10 pounds of elder flowers, two gallons of water, and three ounces of spirits, from which mixture about one gallon is distilled. This distillate is used to flavor wines, jellies, etc. The young flower buds are sometimes pickled like capers. Numerous household remedies are prepared from different parts of the plants. A number of other plants are known by the name elder, as wild elder (*Aralia hispida*), marsh elder (*Iva imbricata*), box elder (*Acer negundo*), poison elder (*Rhus vernia*), etc.

ELDER, JOHN (1824-69). An English engineer and shipbuilder. He was born in Glasgow and was a son of David Elder (died 1866), who built the first marine engine in the establishment of Napier in 1822. He was educated in Glasgow and was a member of the drawing office in Napier's establishment. He was a member of the firm which after 1860 was conducted under the name of Randolph, Elder & Co. and employed more than 4000 men. Elder is especially celebrated as the inventor of the compound or combined high and low pressure engines, in which the economy of fuel amounted to nearly 40 per cent.

ELDER, WILLIAM HENRY (1819-1904). An American prelate. He was born in Baltimore, was educated in that city and at the Collège of

the Propaganda, Rome, was successively professor in and president of Mount St. Mary's College, Emmitsburg, Md., and was consecrated Roman Catholic Bishop of Natchez, Miss., in 1857. For some time he was coadjutor to Archbishop Purcell, of Cincinnati, and upon the death of the latter prelate in 1883 was made his successor.

ELDER STATESMEN. A group of Japanese public men. See JAPAN, section on *History*.

ELDEST SON OF THE CHURCH (Fr. *Fils aîné de l'Eglise*). A title applied in former times to the King of France to show his relation to the church.

ELDON, JOHN SCOTT, EARL OF (1751-1838). Lord High Chancellor of England and one of the greatest of English judges; born at Newcastle-on-Tyne, June 4, 1751. In 1766 he went to Oxford, where his brother was then a tutor, and entered University College. In 1770 he took his bachelor's degree and in 1771 gained the chancellor's prize for an English essay. A clandestine marriage with a Miss Surtees, the daughter of a banker, not only lost him his fellowship and cut off his clerical prospects, but threatened for a time to throw him into mercantile life. However, his brother's influence was strong enough to prevent this, and by his advice John returned to the university, where he supported himself by tutoring and, in the meantime, devoted himself assiduously to the study of law. His legal studies covered a narrow range, being confined almost entirely to Littleton, Coke, and the law reports, but must have been of the most intense and thorough character. In the year 1776, in which he was admitted to the bar, the death of his father placed him in possession of a small but sufficient fortune. In 1783, after only seven years at the bar, he won the distinction of becoming a King's counsel and a bencher of the Middle Temple. In the same year he became a member of Parliament, where he supported the administration of the younger Pitt. Though not a natural orator, and though he never became a good debater, his great energy and the force of his intellect and character made him a valuable and influential member of Parliament and speedily gained for him political preferment. In June, 1788, he was made Solicitor-General and received the honor of knighthood.

In 1793 he was made Attorney-General and in that capacity conducted the famous state trials of the following year. In 1799 he was appointed Chief Justice of the Court of Common Pleas and was raised to the peerage with the title of Baron Eldon, of Eldon, and two years later he became Lord Chancellor of England and, with the exception of the year of the Grenville and Fox administration (1806-07), held that high office until 1827. The great dignity of the chancellorship and its close relations to the crown made it in Eldon's case as much a position of political as of legal authority and influence. The Chancellor of George III, of the Regency, and of George IV, who was at the same time the close friend and the most trusted adviser of the monarch, was practically the mainstay of the crown and government during that long period of Tory ascendancy. His share in the administration of affairs was scarcely disguised by the composition of the successive ministries whose policy he shaped and in whose behalf he used without scruple the great powers of his high office. In 1821, per-

haps as a reward for the part taken by him in the matter of the proposed divorce of the King, he was further honored with the dignity of Viscount Encombe and Earl of Eldon. On the advent of the Canning ministry in 1827 he resigned the great seal and retired to private life. Though not a lawyer of wide and extensive learning, knowing nothing of the Roman jurisprudence or of the civil law of modern Europe, his complete mastery of the common-law system and the subtlety and acuteness of his reasoning powers made him a common-law judge of the highest, or all but the highest, order. It is here that his name most securely rests. Though recognized also as one of the greatest of equity judges, the lack of precision and definiteness in the rules of equity jurisdiction, and the scope which it permitted to the administration of justice on conscientious grounds, proved an embarrassment to his logical mind. He was at his best when he had definite rules and binding precedents to follow or to evade by subtle distinctions. Though he by these very qualities contributed not a little to give definiteness and certainty to the equity system, he allowed the business of the Court of Chancery to fall so much in arrears as seriously to embarrass the administration of justice and to give the court the reputation for dilatoriness from which it still unjustly suffers. He survived his retirement from office for nearly 11 years, dying in London, Jan. 13, 1838. For his life consult: Twiss, *The Public and Private Life of Lord Eldon* (Philadelphia, 1844); Surtees, *Sketch of the Lives of Lords Stowell and Eldon* (London, 1846); Campbell, *Lives of the Lords Chancellors of England* (ib., 1874-75).

ELDORA. A city and the county seat of Hardin Co., Iowa, 27 miles north by west of Marshalltown, on the Minneapolis and St. Louis and the Chicago and Northwestern railroads (Map: Iowa, D 2). Eldora contains a Carnegie library and a park, and the State Industrial School for Boys is near by. The city is in an agricultural and stock-raising region. Deposits of fire and brick clay, building stone, and a workable vein of good coal are near. The manufactures include brick, sewer and drain tile, lumber, flour, and foundry products. There are municipal water works. Pop., 1900, 2233; 1910, 1995.

EL DORADO, ɛl dô-rá'dô, *Sp. pron.* ɛl dô-rá'dô (Sp., the gilded). A term applied, first to a South American king said to cover his body annually with gold dust and bathe in a sacred lake, then to a fabled golden city, and finally to a fabled country abounding to an almost inconceivable degree in gold and precious stones. The legend, whose origin has never been satisfactorily accounted for, took many variant forms, while the mythical king and his equally mythical dominions were shifted with the utmost facility from one part of the continent to another. The story fired the imaginations of the gold-hungry Spaniards, who expended vast sums in sending out exploring parties, most of which returned decimated by privations, fatigue, and disease. The most celebrated expeditions were those of Diego de Ordaz (1531), whose lieutenant, Martinez, claimed to have visited a golden city, called Omoa, and to have been entertained by "El Dorado" himself; and of Orellana (1540-41). In 1595 Sir Walter Raleigh took up the search and described the city as on an

island in "Parima" Lake (in Guiana), which for over two centuries was put down on the maps. Milton's lines will be recalled:

"Guiana, whose great city Geryon's sons
Call *El Dorado*."

Paradise Lost, vi, 410, 411.

The name has since been applied to any place abounding in gold or in opportunities for acquiring sudden wealth and, more recently, to a county in California and a city in Nevada. In literature and especially in poetry frequent references have been made to the legend, the most celebrated of which is probably that in Voltaire's *Candide*, chaps. xvii, xviii. Consult: Markham, *Search for El Dorado* (London, 1861); Van Heuvel, *El Dorado* (New York, 1844); Von Langegg, *El Dorado* (Leipzig, 1888); Bandelier, *The Gilded Man* (New York, 1893); Peters, *Eldorado of the Ancients* (ib., 1902).

EL DORADO. A city and the county seat of Union Co., Ark., 30 miles south-southeast of Camden, on the Chicago, Rock Island, and Pacific, the El Dorado and Wesson, and the St. Louis, Iron Mountain, and Southern railroads (Map: Arkansas, C 4). It contains a courthouse and county jail. El Dorado is in a cotton and peach-growing region and has cotton oil, planing, and stave mills, railroad shops, bottling works, and a foundry. It was incorporated as a city in 1908. Pop., 1900, 1069; 1910, 4202.

ELDORADO. A city in Saline Co., Ill., eight miles northeast of Harrisburg, on the Cleveland, Cincinnati, Chicago, and St. Louis, the Illinois Central, and the Louisville and Nashville railroads (Map: Illinois, H 10). There are coal mines, bottling works, flouring mills, a machine shop and foundry, lumber yards, and manufactories of wire stretchers, wash boilers, medicines, candy, cigars, and brick and tile. Pop., 1900, 1445; 1910, 3366.

ELDORADO. A city and the county seat of Butler Co., Kans., 31 miles east by north of Wichita, on the Missouri Pacific, the Atchison, Topeka, and Santa Fe, and the Kansas City, Mexico, and Orient railroads, and on the Walnut River (Map: Kansas, F 7). It carries on a large trade in grain, live stock, and farm and dairy products, and has machine shops, carriage works, and limestone quarries. Eldorado was settled in 1858 and incorporated in 1870. It contains a Carnegie library. The water works are municipally owned. Pop., 1900, 3456; 1910, 3129.

ELDORADO SPRINGS. A city in Cedar Co., Mo., 100 miles southeast of Kansas City, on the Missouri, Kansas, and Texas Railroad. There are mineral springs with medicinal properties, the bottling of whose water constitutes the chief industry. Farming and stock raising are also carried on. The city owns its water works. Pop., 1900, 2137; 1910, 2503.

ELD'S DEER; also called **BURMESE**, or **BROWN-ANTLER, DEER.** A rusine deer (*Cervus eldi*) of the Malayan region and the island of Hainan. It is about 4 feet in height and frequents open swampy places, often gathering into large bands and resembling the Indian swamp deer in habits. It has a unique form of antler, the brow tine curving down over the forehead in a long sweep and the upper part consisting of many short points. Its native name in Burma is *thamyn*. It is one of the rarest of deer in captivity, and specimens have been obtained

only by sending special expeditions to northern Burma. It breeds freely, however, in the Zoological Park in New York City. Consult Lydekker, *Deer of All Lands* (London, 1898).

ELE'AN, ERE'TRIAN, or ELEAN-ERE'TRIAN SCHOOL. One of the Socratic schools. It was founded by Phædo (q.v.) at Elis and transplanted by Menedemus to Eretria. We know less of this school than of any of its rivals, the Cyrenaic, the Cynic, and the Megaric schools (qq.v.), to the last named of which it approximated in its doctrines. Consult Zeller, *Socrates and the Socratic Schools* (London, 1877).

ELEANOR (äl'e-nër) CROSSES. The name given to 12 crosses said to mark the stages in the funeral journey of Eleanor, wife of Edward I of England, from Grantham to London, where she was buried in Westminster Abbey. Of these crosses, not all of which are memorial crosses, those at Geddington, Northampton, and Waltham are preserved. See **CHARING CROSS**.

ELEANOR OF AQUITAINE, äk'wî-tân' (c.1122-1204). A queen of France and afterward of England. She was the granddaughter of William IX, Duke of Aquitaine, and succeeded her father in 1137. She was married in the same year to Louis VII of France. Her lively and somewhat frivolous disposition and her love for pleasure did not fit her for the society of a husband who was naturally austere, and who from religious conviction had adopted many ascetic habits. In the Holy Land, whither she accompanied him in 1147, her conduct was scandalous; finally a divorce was pronounced under the pretext of kinship in 1152. Eleanor soon gave her hand and possessions to Henry Plantagenet, who in 1154 mounted the throne of England as Henry II. In 1170 Eleanor induced Henry to invest their son, Richard the Lion-Hearted, with her personal dominions and aided him in his rebellion against Henry II in 1173. Consequently he was placed in confinement, where she remained till the death of her husband (1189). As soon as he died she regained her liberty and reigned as regent until Richard's arrival from France. She also held this position during Richard's absence in the Holy Land, which began in 1190. She continued to be prominent in public affairs, whenever need arose, until she retired to the abbey of Fontevault, where she died, April 1, 1204. By Louis VII she had two daughters; by Henry, five sons and three daughters. Two of her sons, Richard and John, became kings of England and two of her daughters queens, one of Sicily and the other of Sicily. Consult: G. M. G. L., *Anglo-Norman Empire* (London, 1903); Norgate, *England under the Angevin Kings* (ib., 1887); Davis, *England under the Normans and Angevins* (ib., 1905); Adams, *History of England, 1066-1216* (ib., 1905).

ELEATIC SCHOOL. The group of ancient Greek philosophers usually reckoned as beginning with Xenophanes (q.v.), but more properly beginning with Parmenides of Elea, a Greek city of lower Italy, and including Zeno, likewise of Elea, and Melissus of Samos. In opposition to the physical philosophy of the Ionic school (q.v.) and to the doctrine of Heraclitus (q.v.), who asserted that everything is flux, the Eleatic philosophers maintained that the only true reality is changeless being. All change and process and difference are empty illusions. The senses, as furnishing us with a changing con-

tent, are of no value for . . . ought is the organ of knowledge . . . and being are not distinguished. Consult the histories of philosophy by Zeller, Windelband, and Gomperz; also Burnet, *Early Greek Philosophy* (London, 1892). See PARMENIDES; ZENO.

ELECAMPANE (Fr. *enule-campane*, ML. *inula campana*, from Lat. *inula*, elecampane, *campus*, field). A genus of plants of the family Compositæ, nearly allied to *Aster*. The only important species is the common elecampane (*Inula helenium*), a native of damp meadows in the middle and south of Europe, rather rare in the British Isles. It is naturalized in America and has spread extensively. This plant, which is a coarse, stout perennial with large yellow flowers, was formerly much cultivated for its root, which was used in medicine, and still retains its place in the pharmacopœias, although . . . neglected. The root has a faint . . . and a bitter, acrid, and somewhat camphor-like taste. It acts as a gentle stimulant to the organs of secretion, promotes expectoration, and is diuretic and sudorific. It contains inulin, which is closely related to starch, but gives a yellowish instead of a blue color with iodine. The root also contains a peculiar principle called helenin or elecampane camphor, which resembles camphor in some of its properties. A number of species are cultivated for their abundant yellow or orange-colored flowers, which appear early in the summer. For illustration, see Plate of EDELWEISS.

ELECTION (Lat. *electio*, choice, from *eligere*, to choose, from *e*, out + *legere*, to select). As a legal term, the choice, or the right or duty to choose, between two inconsistent alternative rights or benefits. These rights may be accorded by contract, as when a purchaser of property stipulates for the option of paying in money or in other property; or when an insurance company reserves the option of paying the sum for which a building is insured or of rebuilding it. Still more frequently persons are put to an election by a rule of law or of equity. A person whose property has been wrongfully taken may sue the wrongdoer for the value of the property in a contract action, or he may bring an action in tort for the conversion; but he is not entitled to pursue both remedies.

The doctrine of election in equity is said to have its origin in two inconsistent alternative gifts or benefits, one of which the giver has no power to make without, at least, the assent of the donor of the other gift. For example, A gives to B property belonging to C, and by the same instrument—generally a will—gives to C property belonging to A. Here C is put to an election between keeping his own property and rejecting A's gift, or accepting A's gift and turning over to B his (C's) property. This doctrine rests upon the intention of A as disclosed by the whole instrument. That intention clearly is that C shall not receive the gift named for him, unless he accedes to the gift named for B. Another example of election is that to which a widow is frequently put between her right of dower (q.v.) and an inconsistent benefit bestowed by her husband's will.

Election may be made by an express and formal announcement, or it may be, and more frequently is, implied from the conduct of the one entitled or bound to elect. In either case an election is not conclusive, as a rule, unless made with knowledge of all material facts necessary

to an intelligent choice. When made with such knowledge, it is irrevocable. Consult the authorities . . . to under WILL; DOWER.

ELECTION. In theological language, the divine act by which certain individuals are chosen to salvation in Christ. As expressed in the Articles of Religion of the Church of England, election is the doctrine of "God's everlasting purpose, whereby He hath constantly decreed by His secret counsel to deliver from curse and damnation those whom He hath chosen in Christ out of mankind, and to bring them by Christ to everlasting salvation as vessels made to honor."

Although the expressions "election," "elect," etc., are frequent in Scripture, it cannot be said that what is known as the theological doctrine of election was . . . by the Christian Church till the . . . Augustine (q.v.). The controversy between Pelagius and Augustine in the beginning of the fifth century brought out almost all the aspects of the question which have since, at successive epochs in the history of the Church, risen into renewed prominence. The contests between the Scotists and Thomists in the fourteenth century, between the Arminians and Calvinists, and, within the Roman church, between the Jansenists and Molinists in the seventeenth century, are recurring expressions of the same radical conflict or divergency of opinion. Two forms of the doctrines have been held: one, that the election of God is governed by His . . . of man's action; the other, that . . . only by the absolute will of God. The former of these opinions corresponds to the Pelagian or Arminian doctrine of election, the latter to the hyper-Augustinian or Calvinistic. In the view of the Arminian salvation is within the choice of the human will; in the view of the Calvinist the human will is of little or no account—the decree of God is everything—and this decree (which Calvin admitted to be a *decretum horribile*) absolutely determines some to everlasting life and some to everlasting death. The separation has its source in the will of God and not in the moral conditions of mankind. In the one case election . . . upon the foreknowledge by God of . . . part of the elect; in the other, faith itself proceeds from . . . is thus conditioned upon election, which . . . the ground of the foreknowledge of faith. This question is evidently the question of "prevenient grace" (see GRACE), for election is only the eternal purpose in respect to grace. See FOREKNOWLEDGE AND FOREORDINATION.

ELECTION, in politics, is the choice of public officers by the vote of those who are entitled to exercise the elective franchise. This is to be distinguished, on the one hand, from the appointment of officers by a superior, as by a king, a president, a governor, or a mayor; and, on the other hand, from their selection by lot. The last-named method of choosing public officers was considered by Aristotle one of the characteristic features of a popular government. It has been advocated by other writers, because of its tendency to prevent the formation of political parties. Party organization, the caucus, the coalition of different factions, the corruption of voters, the falsification of election returns, the interest of a particular candidate, and kindred evils, it is argued, will all be swept away if officers are selected by lot.

When officers are chosen, by the great body of the voting population, the election is spoken of as *popular* or *direct*. This is the prevailing form in free government at present. It had its origin in the general assemblies of primitive states, such as the Roman Concilia, the Athenian Ecclesia, the Teutonic Assembly of Free-men. After the establishment of the Roman Empire popular election became a farce and finally disappeared as a political institution of the Roman state. It was continued, however, in the ecclesiastical government of the Christian Church and reappeared throughout Europe in the guilds of all kinds, whose members chose their officers, as well as in the free towns, whose citizens elected their municipal officers to attend to local affairs and their representatives to take part in the deliberations and legislation of parliaments or the States-General. Election is said to be *indirect* or *representative* when it is limited to a comparatively small body whose members have themselves been chosen by the general mass of electors. Elective monarchs have usually been selected in this way. Examples may be found in the case of the former kings of Poland and Hungary and of the head of the old German Empire. At times the choice of candidates for kingship has been limited to a certain family, while the right of voting was exercisable by all the free-men. Such appears to have been the early practice of most Teutonic states. As a state enlarges, this practice is generally modified. Dr. Stubbs tells us that the election of the King in Anglo-Saxon England was exercised in form and substance, to the great extent, by that body in the general assemblies of the whole nation. A striking example of indirect or representative elections in our time was afforded by the choice of United States Senators by the legislatures of the various States from the adoption of the Constitution until the ratification in 1913, of the Seventeenth Amendment. In theory the President of the United States is selected by the presidential electors chosen in each State. In practice, however, these electors cast their votes for the party candidate.

Another classification of elections is based upon the governmental functions of the offices to which persons are chosen. An election is *national* which has for its object the selection of national officers, such as members of the United States House of Representatives, who are chosen every two years, and the President and Vice President, who are chosen every four years. It is styled a *State* election when held for the choice of State officers, such as Governor, Lieutenant Governor, and members of the State Legislature. If the political duties of an officer are confined to a particular subdivision of the State, such as a town, a city, or a county, his election is known as municipal.

Any fraudulent act tending to defeat an honest, free, fair, and pure election is a criminal offense at common law. Various statutes have been passed in almost every State for the express purpose of securing to voters entire freedom of action and of preventing improper practices in voting, in receiving votes, in counting votes, and in registering the results. The validity and regularity of elections are not infrequently disputed, and such disputes present important questions for the courts or for special tribunals. Of the latter class, the most

famous in the history of this country is the Presidential Electoral Commission of 1877, constituted of five Senators, five members of the House of Representatives, and five associate justices of the United States Supreme Court, which decided the contest between Tilden and Hayes. By the Federal Constitution each House of Congress is the final judge of the election of its members, and a similar provision relating to the State legislatures is found in most of the State constitutions. It must be confessed that in cases of contested election in Congress or State legislatures purely partisan considerations have in great measure affected the decision. Contested parliamentary elections in Great Britain are determined by the courts and not by the House of Commons.

Election officers, whether inspectors at the various voting precincts or members of a county or State board of canvassers, perform merely ministerial functions. They are not judicial or quasi-judicial officers. Their duty is to do the things prescribed by statute and not to pass judgment upon disputed questions. If they go beyond their ministerial duties and attempt to exercise judicial functions, they subject themselves to an action for damages by any person legally wronged, as well as to criminal punishment. Consult: *People vs. Board of Canvassers*, 129 N. Y. 371-372; *People vs. Rice*, 129 N. Y. 465-466; Aristotle, *Politics*, ed. by Weldon (London, 1882); Freeman, *Comparative Politics* (ib., 1873); Woolsey, *Political Science* (New York, 1877); Stanwood, *Presidential Elections* (1892); Wigmore, *Australian Ballot System* (Boston, 1889); New York State Legislature, *Report of Joint Committee Appointed to Investigate Primary and Election Laws in New York and Other States* (Albany, 1910); Jones, *Readings on Parties and Elections in the United States* (New York, 1912). See BALLOT; ELECTORAL REFORM; SUFFRAGE; VOTE.

ELECTION, PRIMARY. See PRIMARY ELECTION.

ELECTION CAKE. A rich loaf cake which, in the days when Connecticut held an annual election, formed an important part of the refreshments offered to visitors to its State capital.

ELECTION COMMITTEE. See CONGRESS, UNITED STATES.

ELECTIVE AFFINITIES. A term expressing an old conception of the cause of chemical changes. According to that conception, if a given substance is brought into contact with two other substances, with either of which it is capable of combining, it will enter into combination with the one for which it has the greater affinity. Elective affinity was thus supposed to be the sole determining factor of chemical changes. At present this idea is known to be false, or rather to require very important limitation. "Affinity," while one of the factors determining the course of chemical change, is not the only factor, the active masses of substances and the temperature being known to have a definite influence in all cases. See BERGMAN; BERTHOLLET; AFFINITY, CHEMICAL; REACTION; ELECTROCHEMISTRY; THERMOCHEMISTRY.

ELECTIVE COURSES and ELECTIVE STUDIES. Terms that have come into common use during the last 30 or 40 years in American colleges, and to a great extent in establishments for secondary education, to indicate the

studies which may be elected or chosen by undergraduate students. The principle has been imitated to some degree in the secondary schools of Europe, especially those of France. In earlier days there was a required curriculum which must be followed by all candidates for the degree of B.A. At a later period, to meet the special needs or wishes of individuals, certain studies were made "optional"—modern languages, e.g., the higher branches of mathematics, botany, surveying, and other scientific or technical branches. The rapid growth of science and the enlarged resources of the colleges were naturally followed by enlargement of the teaching forces and by provision for instruction in subjects before neglected. Choice became imperative. To a considerable extent this necessity was recognized and satisfied by the foundation of technical or scientific schools, sometimes departments of or annexes to the old colleges, sometimes independent establishments. Gradually the old curriculum, often called the regular college course, yielded to the same influences. A few institutions still adhere, with commendable pride, to the theory of a liberal education based upon the classics and mathematics—antecedent to the time-honored baccalaureate degree. Yet the American colleges generally offer in these days a very considerable freedom in the selection of subjects to which the student may devote his time. There are certain inherent dangers in this freedom. The love of ease may lead to the selection of courses—which are called "soft" in college parlance—exacting but little mental effort; or the ignorance and inexperience of youth may lead to selections which will be regretted in mature life. To obviate such dangers, it is common to lay before the student a "group" of subjects which form a good combination. With more or less emphasis these groups are commended to students. As a further guide to the wise selection of subjects, members of a faculty are always ready to give advice, and in some places those teachers who are most interested in pedagogics are officially recognized as "advisers"—a term which seems to have been introduced to supersede that of tutors, who were regarded rather as disciplinarians than as counselors. On the whole, the establishment of elective courses marks a propitious advance in higher education. The system works well wherever due care is exercised by the authorities to secure industry, application, and concentration. The University of Virginia was a pioneer in the provision of electives. Most of the State universities are now thoroughly committed to the principle. The older colleges, led by Harvard, have adopted it to a greater or less extent. The new foundations—Cornell, Johns Hopkins, Chicago, and Leland Stanford Junior—have never felt the fetters of a traditional curriculum.

The exact position of any college can be ascertained only by reference to its latest announcements, for changes frequently occur in the subjects offered and in the technical requirements for degrees. Consult: Butler, *Education in the United States* (Albany, 1900); Eliot, *Educational Reform* (New York, 1898); W. T. Foster, *The Administration of the College Curriculum* (Boston, 1911). *The Educational Review* (New York, 1891 et seq.). See COLLEGES, AMERICAN; UNIVERSITY; and the various institutions.

ELECTORAL COLLEGE. In the political system of the United States, the body of electors in each State who have been chosen to select the President and Vice President. The expression does not appear in the Constitution or statutes, but is a popular designation of the electors, adopted by analogy to the college of cardinals, to which the choice of the popes is committed. It is sometimes employed of the whole body of electors for President and Vice President, chosen by all the States. The Constitution prescribes (Art. II; and Amendments, Art. XII) the number of electors and the manner in which they shall exercise their high functions, but leaves to the States the mode of appointing them and to Congress the power to determine a uniform time for choosing them and the day on which they shall give their votes. Accordingly the members of the electoral college in each and every State are chosen simultaneously by popular vote on the Tuesday next after the first Monday in November. Their number is equal to the whole number of Representatives which the State sends to both branches of Congress. They are required to meet at some place designated by the Legislature of their State on the second Monday in January, and then and there to vote by ballot for President and Vice President, of whom one, at least, shall not be a resident of the same State with themselves. Each electoral college then makes a list of the names of all its candidates for President and Vice President, with the number of votes for each; the list is signed and certified by every member of the college, is authenticated by the Governor of the State, and transmitted to the President of the Senate of the United States. On the second Wednesday in February the electoral votes are opened and counted in presence of both Houses of Congress, assembled in the chamber of Representatives, and the result is announced by the President of the Senate. The persons who receive the highest number of votes, respectively, for the offices of President and Vice President are declared elected, provided they have received a majority of all the votes. In case of a tie the House of Representatives, voting by States, each State having one vote, is to choose between the equal candidates for President, a majority of all the States being necessary to a choice. The Senate has the power to choose in case of a tie in the vote for Vice President. In the same way, in case there is no tie, but the leading candidates fail to receive a majority of all the votes, the election for President is thrown into the House, and that for Vice President into the Senate. Under the Constitution as originally framed the electoral colleges did not determine their choice for President or Vice President, but when the total votes were counted by the President of the Senate, the candidate receiving the highest number of votes was declared to be elected President, and his nearest competitor Vice President. But the Twelfth Amendment to the Constitution, adopted in 1804, changed the mode of voting for the two officers, the electors being required to vote separately for President and Vice President.

The present position and functions of the electoral college furnish a striking illustration of the way in which a written and stable constitution may be undermined and amended by the silent process of customary observance. It is obvious that the Constitution contemplates that

the electoral college in each State shall be a deliberative body, freely exercising an untrammelled choice for the high offices which they are called upon to fill. They are not required, nor are they expected, to vote as a unit, still less to meet for the sole purpose of registering a result which has already been reached elsewhere and by others. That this remarkable change in the conception of the constitutional functions of the electoral college has been brought about is due to the course of our political development, and particularly to the national-convention system of nominating candidates for the presidency and vice presidency. These conventions are not recognized by the Constitution, nor have their nominations any legally binding force. But the electors, subsequently nominated and elected for the sole purpose of giving the vote of the State to a certain party candidate, are as securely bound to that course of action by custom and honor as they would be by statute. The people, consequently, elect the President and Vice President by States, and the college is a cumbrous machine for formally conveying to Washington the wishes of the majority. Since 1801, with one exception (the disputed election of President Hayes in 1877), the vote of an elector has been known with certainty several weeks before it is cast and several months before it is officially announced. The electoral system has constantly endangered the State, on account of the absence, until recently, of any general law to govern the President of the Senate in his canvass of the votes, and the tendency of Congress to decide every case of doubt or disputed returns arbitrarily as it arose. Nothing was accomplished, however, until 1887, when, as a result of the Hayes-Tilden election contest, a law was passed (approved February 3) to cover the contingency of rival electoral colleges and disputed returns. Under the terms of this act each State is conceded to have the right of determining all controversies or contests regarding the appointment of its own presidential electors; and in case of any such contest Congress is to accept the State's settlement of the same as conclusive, and it cannot reject any electoral vote, duly certified, unless both Houses concurrently decide that that vote has been irregularly given. If more than one return from a State is received, only those votes are to be counted which the State itself has indorsed as regular; but if the State has been unable to settle the question, owing to its having two or more rival sets of authorities, or from any other cause, then the two Houses are to decide the dispute. See CONSTITUTION OF THE UNITED STATES; CONVENTION; PRESIDENT; and the authorities there referred to.

ELECTORAL COMMISSION. In United States history, the body of men provided for by an Act of Congress, approved Jan. 29, 1877, to settle certain disputed questions in regard to the electoral votes of several States in the presidential election of 1876. As the counting of the electoral votes in the presence of the two Houses of Congress proceeded according to custom, it had been found that there were conflicting certificates from four different States—Florida, Louisiana, Oregon, and South Carolina; and the two Houses were unable to agree in any case which certificate should be received as genuine. The Senate at the time was controlled by the Republican party, the House of

Representatives by the Democratic party, and there was thought to be danger of civil disturbances on account of certain questions likely to arise in the counting of the electoral votes. Under these circumstances a majority of each of the two political parties in Congress agreed to create a commission to be composed of five Senators chosen by the Senate; five members of the House of Representatives, chosen by that body; and five associate justices of the Supreme Court, four of whom were designated by the act of Congress, and the fifth of whom was to be selected by the four—to which commission should be referred, for judgment and decision, the question which of two or more conflicting certificates received from any State of the votes cast by the electoral college of such State for President and Vice President in the election of 1876 was the certificate provided for in the Constitution of the United States. The judgment of the commission in any matters referred to it, unless set aside by the concurrent action of the Houses of Congress, was to be final. The proposed law was thereupon enacted, and the Senate appointed three Republicans and two Democrats, and the House of Representatives three Democrats and two Republicans, as members of the commission. Of the four associate justices of the Supreme Court who were named in the law, two were understood to be Democrats and two Republicans; and these selected as the fifth associate justice to serve with them upon the commission, Mr. Justice Bradley, a Republican, the only member not selected avowedly as a partisan. The commission was constituted as follows: Justices Clifford, Strong, Miller Field, and Bradley; Senators Edmunds, Morton, Frelinghuysen, Thurman, and Bayard; and Representatives Payne, Hunton, Abbott, Garfield, and Hoar. Upon the illness of Senator Thurman his place was filled by the choice of Senator Kernan. The certificates and accompanying papers were successively referred to the commission, which proceeded to hear argument upon the questions involved. A notable group of distinguished lawyers participated in the conduct of the case, William M. Evarts, Stanley Matthews, E. W. Stoughton, and Samuel J. May representing the Republicans, and J. S. Black, Matthew H. Carpenter, Charles O'Connor, J. A. Campbell, Lyman Trumbull, Ashbel Green, Montgomery Blair, George Hoadley, William C. Whitney, R. T. Merrick, and A. P. Morse representing the Democrats. The result in the case of each State was a decision of the commission, by a vote of 8 to 7—the vote following the line of party division in the body—that the certificate of the electoral votes cast for Hayes and Wheeler, the Republican candidates for President and Vice President, was the certificate which contained the lawful electoral vote of said State, and that the other certificates were illegal and void. The Republican Senate concurred in this judgment in each case, while the Democratic House of Representatives dissented. The decision of the commission, therefore, according to the terms of the statute, became irrevocable; the electoral votes were counted accordingly; and Rutherford B. Hayes and William A. Wheeler were found duly elected, by a majority of one electoral vote, respectively President and Vice President for a term of four years, from March 4, 1877. The controlling question before the commission was whether—an electoral certificate being in form according to law, as

those in favor of the Republican candidates were—it was competent for Congress or the commission to go behind the same and take evidence modifying or explanatory (*alvunde*) in support of alleged irregularities and frauds committed before such certificate was issued. For the choice of Republican electors in Louisiana had been accomplished only by the rejection of several thousand Democratic votes by a Republican returning board. Upon this question the Democrats in Congress and in the commission took the one side, while the Republicans took the other. There can hardly be a question that the latter was morally entitled to the presidency. The full proceedings of the commission were published as part iv, vol. v, of the *Congressional Record* of 1877. Consult: Rhodes, *History of the United States from the Compromise of 1850*, vol. vii (New York, 1906); Haworth, *The ... Disputed Presidential Election of ... 1906*; Burgess, "The Law of the Electoral Count," *Political Science Quarterly*, vol. iii (1888).

ELECTORAL REFORM. In general, any improvement by law or custom in the manner of ... elections to public office. Specifically, ... describes the movement of the last 100 years for the purification of elections in Great Britain and the United States.

It is of the utmost importance, in a state whose government rests wholly or in great part on popular suffrage, that public elections should be free and honest. When they are of this character, public officials ... of the people, and the ... which such officials adopt ... popular will. The tendency, however, in every representative government is towards the control of nominating conventions and of elections by small bodies of men whose energies are chiefly directed to the manipulation of caucuses and party machinery. While the great mass of electors are engrossed in the conduct of their private affairs, these professional politicians, taking advantage of the popular apathy, dictate nominations to office, force party conventions to register their secret choices, and control the entire machinery of elections.

Accordingly agitation for electoral reforms has usually been directed towards one of three ends: (1) a change in the qualifications of electors; (2) securing to electors the free and effective expression of their choice of officers; (3) the punishment of those guilty of corrupt practices in connection with elections.

1. **Qualifications of Electors.** Both in Great Britain and in the United States the state has treated the elective franchise as a privilege of its citizens, and not as one of their natural rights. Hence it has bestowed that privilege from time to time upon those, and those only, who it has been considered would use it wisely and for the best interests of the state. Public opinion concerning the proper qualifications of voters has undergone many changes during the last 100 years. In the main ... been in the direction of extending the franchise to new classes of voters, of broadening the basis of the electorate. When the United States became independent, suffrage was limited in every one of the commonwealths to property owners. In Massachusetts it was required not only that the voter be of age, but that he be the owner of real estate worth £60 sterling, or of a freehold yielding £3 annual income. In New York it

was necessary that he be seised of a freehold worth £20, or pay a rent of 40 shillings a year, and have his name on the list of taxpayers. South Carolina insisted upon the voter being a white freeman and freeholder and believing in the existence of a God and in a future state of rewards and punishment.

During the last century, however, most of the States accepted the theory of universal manhood suffrage, and extended the elective franchise to all male citizens of 21 years and upward, while a few of the States have granted to women also the privilege of voting. Although the tide of electoral reform in this country has set mainly in the direction of universal suffrage, in some States its purpose has been to impose restrictions upon the elective franchise. California, e.g., has enacted that no person who is unable to read the State constitution in the English language and write his name shall ever exercise the privilege of a State elector. Connecticut and Massachusetts impose somewhat similar restrictions upon voters. Several of the Southern States have recently limited the suffrage by imposing educational qualifications upon voters or by requiring them to pay certain taxes. This policy has for its prime object the disqualification of ignorant and indigent negroes. In Louisiana persons are permitted to vote who do not possess the prescribed qualifications, provided they were entitled to vote on Jan. 1, 1867, or are sons or grandsons of persons thus entitled. The class thus excepted includes poor and illiterate whites. In some other Southern States the same end is effected through the ... of qualifications as to property and literacy for which veterans, Federal and Confederate, of the Civil War, as well as of earlier wars of the United States, are exempt. The chief reliance in the greater part of the South for the exclusion of the negro vote consists in the administration of property and literacy tests general in their terms.

Such restrictions as now exist upon male suffrage have given rise to very little popular agitation in recent years, although periodical motions are introduced in Congress to inquire into restrictions upon the negro vote in the South. Chief interest in the reform of suffrage qualifications centres in the question of woman's suffrage. Since 1869 women have voted on equal terms with men in Wyoming. They possessed full suffrage, in 1914, in eight other States. See WOMAN SUFFRAGE.

In Great Britain the trend of electoral reform has followed the same general course as in the United States, although it has not yet reached the goal of universal manhood suffrage. The electorate has been extended several times, until it includes not only copyholders, leaseholders, and householders of premises of small values, but also men occupying lodgings of the yearly value of £10. As in the United States, interest in electoral reform centres chiefly in the question of woman suffrage (q.v.).

2. **Protection of Voters.** It is of prime importance that perfect freedom of choice should be secured to electors. Hence the secret ballot has been substituted for the viva voce vote (see BALLOT), and bribery and intimidation of electors are treated as grave criminal offenses. Not only should the elector be allowed to exercise his free choice at the polls, but that freedom ought not to be rendered ineffective by the improper manipulation of caucuses or primaries, or by

giving to the voters of some districts undue advantage over others. The caucus or primary is a meeting of the members of a particular political party or group for the purpose of nominating candidates for office within a prescribed district, or of electing delegates to larger conventions of the party, or of declaring party principles. These gatherings have often been controlled by unscrupulous persons, who have not hesitated to resort to fraud and violence. In order that the party caucus or primary should reflect the views of the majority of the party electors of the district, statutes have been enacted in several States surrounding those voluntary gatherings with many of the legal safeguards which protect general elections. The place and time for the caucus or primary are fixed by law, the manner of registration and voting is prescribed, and severe criminal penalties are affixed to fraudulent or violent manipulations of these meetings. In most States primary laws apply only to State and local elections. A few States, however, have laws providing primary elections for presidential candidates also, and in 1912 the presidential primary was employed in several States through the action of the party organization.

While this legal regulation of the primary has done much to mitigate its evils, it is still open to the objection that it leaves the control of the nominating system in the hands of the party managers and practically excludes the independent voter from exercising any considerable influence in the selection of candidates for public office. The recent increase in the number of independent voters has given them new weight in politics, and they are now demanding a further reform, which has in contemplation the substitution of "direct" for primary and caucus nominations. This is to be effected by permitting a specified number of registered voters to place a candidate in nomination directly, by a written declaration signed by them, and without the intervention of the machinery of caucuses and conventions now employed. Several Western States have laws favoring direct nominations, but since these laws do not interfere with party tickets, their chief effect has been to facilitate the candidacy of independents without seriously impairing party control. A device that has recently been introduced for the purpose of reducing party influence over elections is that of preferential voting. By this device the voter registers not only his first choice, but his second, third, etc., for each elective office. If no candidate has a majority of first choices, second choices are canvassed and given full weight in determining the outcome. Various devices for determining the relative preference of the voters are in use. The plan in its various modifications is in use in *West Australia* (1907), *South Africa* (1909), *Grand Junction, Colo.* (1909), *Spokane* (1911). Several other cities have adopted the plan. See **MUNICIPAL GOVERNMENT**.

A flagrant example of the control of elections by corrupt party managers was formerly afforded by the pocket and rotten boroughs of England, which were disfranchised by the Reform Bill of 1832. These were boroughs (having the right to elect members of Parliament) that were controlled by nonresident noblemen, either by reason of their landed proprietorship or of their purchase of the electors. In many of them the number of voters was very small. For example, the borough of Gatton had but seven electors,

and that of Old Sarum but one—the keeper of an alehouse. When Lord Russell introduced his Reform Bill in 1831, 90 members of Parliament were returned by 46 boroughs with less than 50 votes each, and a majority of the House of Commons was elected by 15,000 out of 3,000,000 male adults. One peer controlled boroughs which sent up 11 members of his choice to the House of Commons, while some of the great manufacturing centres had no representation in Parliament. The Reform Bill disfranchised 56 of these rotten boroughs and made a new distribution of parliamentary representatives throughout the kingdom.

The Fifteenth Amendment to the Federal Constitution provides that "the right of the citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color, or previous condition of servitude," and vests Congress with power to enforce this provision by appropriate legislation. The Fourteenth Amendment prescribed, as the penalty for the abridgment of the right to vote by a State, reduction in the representation in Congress of that State. Although several States have in effect deprived negro citizens of the right to vote, Congress has enacted no legislation to enforce this constitutional provision.

3. Corrupt Electoral Practices. The most heinous of these are false personation and repeating by voters, and bribery and intimidation by candidates for office or their partisans. Both in Great Britain and in the United States repeated efforts have been made by legislators to eradicate these practices, but without entire success. Perhaps the most comprehensive and rigorous piece of legislation of this sort is the British Corrupt Practices Act of 1883, with its amendments. Its principal features are: (1) the severe penalties inflicted upon those guilty of false personation at the polls or of voting more than once at the same election, as well as upon all who indulge in the intimidation, undue influence, or bribery of voters; (2) the restriction within very narrow limits of the employment of paid agents, clerks, messengers, and others by candidates or election committees; (3) the prescribing of a fixed scale of lawful expenditures by candidates and committees; (4) requiring a full and correct account of such expenditures. Several of the United States have laws of a similar character. Although none of them are as sweeping or as effective as the British act, their results have been beneficial.

Some of the grosser forms of fraud at elections, such as the use of fraudulent and tissue ballots and the stuffing of ballot boxes, have been rendered obsolete by the adoption of the Australian ballot, and the assumption by the State of the duty of furnishing an official ballot in place of the party ballot formerly provided by the several party organizations.

The provision for the retirement of an elective officer before the expiration of his term of office, known as the "recall," has been widely discussed and has gained headway in the last few years. By this plan a petition signed by a certain proportion of the voters in the previous election can bring about another election to determine whether an accused officer shall be retained or another elected. The plan was first officially adopted in the Los Angeles charter of 1902. The device was soon adopted by a considerable number of California cities. In 1908 the recall was adopted by State constitutional amendment

in Oregon. California (1911) and Arizona (1912) also amended their constitutions to provide for the recall. The device has been widely adopted in city charters. See RECALL.

Within the last few years a movement known as the "short ballot" has made considerable headway, especially in connection with the commission form of government for towns and cities. (See MUNICIPAL GOVERNMENT.) This is an attempt to reduce the number of elective officers by reducing the offices to be filled at one election to a reasonable number. The idea of this plan is to simplify the voters' task and thus make possible a more intelligent and more honest use of the ballot. See BALLOT; CORRUPT PRACTICES; ELECTION; VOTING MACHINE; INITIATIVE; and REFERENDUM. Consult: Bishop, *Colonial Elections* (New York, 1893); Dallinger, *Nominations for Elective Office* (ib., 1897); Stüres, *Primary Election Legislation* (ib., 1898); Ward, *Treatise on the Law Relating to Parliamentary and Municipal Elections* (2d ed., London, 1886); Wilson, *The State* (New York, 1900); id., *Constitutional Government in the United States* (ib., 1908); Commons, *Proportional Representation* (ib., 1907); *Loose Leaf Digest of Short Ballot Charters* (ib., 1911); Bacon and Wyman, *Direct Elections and Law Making by Popular Vote* (Boston, 1912).

ELECTORAL VOTES. The votes cast by presidential electors in the United States for presidential and vice-presidential candidates. The candidates for the two offices were not voted for until after 1805, before which time the electors were receiving the largest total number of votes at any given election was declared President, and the one receiving the next largest number the Vice President. The electoral votes cast in the various campaigns since 1789 have been as follows: In 1789: George Washington, 69; John Adams, 34; Samuel Huntington, 2; John Jay, 9; John Hancock, 4; Robert H. Harrison, 6; George Clinton, 3; John Rutledge, 6; John Milton, 2; James Armstrong, Edward Telfair, and Benjamin Lincoln, each, 1. In 1793: George Washington, 68; John Adams, 77; George Clinton, 13; Thomas Jefferson, 4; Aaron Burr, 1. In 1797: John Adams, 71; Thomas Jefferson, 68; Thomas Pinckney, 59; Aaron Burr, 30; Samuel Adams, 15; Oliver Ellsworth, 11; George Clinton, 7; John Jay, 5; James Iredell, 3; Samuel Johnston, 1; John Henry, each, 2; George Clinton, 1. In 1801: Thomas Jefferson and Aaron Burr, each, 73; John Adams, 65; C. C. Pinckney, 64; John Jay, 1. In 1805: for President, Thomas Jefferson, 162; C. C. Pinckney, 14; for Vice President, George Clinton, 162; Rufus King, 14. In 1809: for President, James Madison, 122; C. C. Pinckney, 47; George Clinton, 6; for Vice President, George Clinton, 113; Rufus King, 47; John Langdon, 9; James Monroe, 3; and James Madison, 3. In 1813: for President, James Madison, 128; De Witt Clinton, 89; for Vice President, Elbridge Gerry, 131; Jared Ingersoll, 86. In 1817: for President, James Monroe, 183; Rufus King, 34; for Vice President, Daniel D. Tompkins, 183; John E. Howard, 22; James Ross, 5; John Marshall, 4; Robert G. Harper, 3. In 1821: for President, James Monroe, 231; John Q. Adams, 1; for Vice President, Daniel D. Tompkins, 218; Richard Stockton, 8; Daniel Rodney, 4; Robert G. Harper, Richard Rush, each, 1. In 1825: for President, John Q. Adams, 84; Wil-

liam H. Crawford, 41; Andrew Jackson, 99; Henry Clay, 37; for Vice President, John C. Calhoun, 182; Nathan Sanford, 30; Nathaniel Macon, 24; Andrew Jackson, 13; Martin Van Buren, 9; Henry Clay, 2. In 1829: for President, Andrew Jackson, 178; John Quincy Adams, 83; for Vice President, John C. Calhoun, 171; Richard Rush, 83; William Smith, 7. In 1833: for President, Andrew Jackson, 219; Henry Clay, 49; John Floyd, 11; William Wirt, 7; for Vice President, Martin Van Buren, 189; John Sergeant, 49; William Wilkins, 30; Henry Lee, 11; Amos Ellmaker, 7. In 1837: for President, Martin Van Buren, 170; William H. Harrison, 73; Hugh L. White, 26; Daniel Webster, 14; Willie P. Ma: r: r: 11; for Vice President, Richard M. Johnson, 147; Francis Granger, 77; John Tyler, 47; William Smith, 23. In 1841: for President, William H. Harrison, 234; Martin Van Buren, 60; for Vice President, John Tyler, 234; Richard M. Johnson, 48; Lyttleton W. Tazewell, 11; James K. Polk, 1. In 1845: for President, James K. Polk, 170; Henry Clay, 105; for Vice President, George M. Dallas, 170; Theodore Frelinghuysen, 105. In 1849: for President, Zachary Taylor, 163; Lewis Cass, 127; for Vice President, Millard Fillmore, 163; William O. Butler, 127. In 1853: for President, Franklin Pierce, 254; Winfield Scott, 42; for Vice President, William R. King, 254; William A. Graham, 42. In 1857: for President, James Buchanan, 174; John C. Frémont, 114; Millard Fillmore, 8; for Vice President, John C. Frémont, 174; William L. Dayton, 114; A. A. Revere, 3. In 1861: for President, Abraham Lincoln, 180; John C. Breckenridge, 72; Stephen A. Douglas, 12; John Bell, 39; for Vice President, Hannibal Hamlin, 180; Joseph Lane, 72; Herschel V. Johnson, 12; Edward Everett, 39. In 1865: for President, Abraham Lincoln, 212; George B. McClellan, 21; for Vice President, Andrew Johnson, 212; George H. Pendleton, 21. In 1869: for President, Ulysses S. Grant, 214; Horatio Seymour, 80; for Vice President, Schuyler Colfax, 214; Frank P. Blair, Jr., 80. In 1873: for President, Ulysses S. Grant, 286; Thomas A. Hendricks, 42; B. Gratz Brown, 18 (Horace Greeley having died in November, 1872); Charles J. Jenkins, 2; David Davis, 1; for Vice President, Henry Wilson, 286; B. Gratz Brown, 47; G. W. Julian, A. H. Colquitt, each, 5; J. M. Palmer, T. E. Bramlette, each, 3; W. S. Groesbeck, W. B. Machen, N. P. Banks, each, 1. In 1877: for President, Rutherford B. Hayes, 185; Samuel J. Tilden, 184; for Vice President, William A. Wheeler, 185; Thomas A. Hendricks, 184. In 1881: for President, James A. Garfield, 214; Winfield S. Hancock, 155; for Vice President, Chester A. Arthur, 214; William H. English, 155. In 1885: for President, Grover Cleveland, 219; James G. Blaine, 182; for Vice President, Thomas A. Hendricks, 219; John A. Logan, 182. In 1889: for President, Benjamin Harrison, 233; Grover Cleveland, 168; for Vice President, Levi P. Morton, 233; Allen G. Thurman, 168. In 1893: for President, Grover Cleveland, 277; Benjamin Harrison, 145; J. B. Weaver, 22; for Vice President, A. E. Stevenson, 277; W. Reid, 145; J. G. Field, 22. In 1897: for President, William McKinley, 271; William J. Bryan, 176; for Vice President, Garret A. Hobart, 271; Arthur Sewall, 149; Thomas E. Watson, 27. In 1901: for President, William McKinley, 292; William J. Bryan, 155; for Vice President, Theodore Roosevelt, 292; A. E. Stevenson, 155. In 1904: for President,

Theodore Roosevelt, 336; Alton B. Parker, 140; for *Vice President*, C. W. Fairbanks, 336; H. G. Davis, 140. In 1908: for *President*, William H. Taft, 321; William J. Bryan, 162; for *Vice President*, James S. Sherman, 321; John W. Kern, 162. In 1912: for *President*, Woodrow Wilson, 435; Theodore Roosevelt, 88; William H. Taft, 8; for *Vice President*, Thomas R. Marshall, 435; Hiram Johnson, 88; Nicholas M. Butler, 8. Consult: McClure, *Our Presidents* (New York, 1905); Stanwood, *History of the Presidency, from 1788 to 1897* (Boston, 1898, 1912); *History of the Presidency from 1897 to 1912* (ib., 1912).

ELECTORS, GERMAN IMPERIAL (Lat., from *eligere*, to choose). In the Holy Roman Empire, the college of lay and ecclesiastical princes in whom the right of choosing the King of the Romans was vested. With the extinction of the Carolingian line after the breaking up of the Empire of Charles the Great, the kingship in Germany became elective, the right of election residing in certain of the great feudatories, though just in whom or on what grounds is not clear from the early mediæval accounts. An electoral body is vaguely mentioned in chronicles of 1152, 1198, and 1230. The electoral college was first clearly defined in 1356 in the Golden Bull, a constitution for the Holy Roman Empire, issued by the Emperor Charles IV. This document also prescribed the exact form and manner of election of the "King of the Romans and future Emperor." Its statements seem to indicate that the right of election had been attached to certain hereditary offices in the Imperial Court, as each prince elector is associated with such an office. The electors were the Archbishop of Mainz (Mayence), Arch-Chancellor of the Holy Empire for Germany; the Archbishop of Cologne, Arch-Chancellor for Italy; the Archbishop of Treves (Triers), Arch-Chancellor for the Gallic Provinces and Arles; the King of Bohemia, Arch-Cupbearer; the Count Palatine of the Rhine, Arch-Steward; the Duke of Saxony, Arch-Marshal; and the Margrave of Brandenburg, Arch-Chamberlain. The German Princes held that an election as King of the Romans by the German electors was also an election as Holy Roman Emperor; but the popes contended that they alone, as vicars of God, could bestow the Imperial dignity. The Peace of Westphalia (1648) created an eighth electorate for the heirs of the Count Palatine, Frederick V, who had been despoiled of his electorate in behalf of the Duke of Bavaria in the Thirty Years' War. A ninth, that of Brunswick-Lüneburg, was created in 1692, and fully established in 1710, as the electorate of Hanover. In 1777 the inheritance of Bavaria by the Elector Palatine restored the number to eight. In 1803, just before the dissolution of the Holy Roman Empire, the number was increased. From the fifteenth century the electors constituted a separate college in the Imperial Diet. Consult Bryce, *The Holy Roman Empire* (London, 1892). The Golden Bull is translated in Henderson, *Select Historical Documents of the Middle Ages* (ib., 1892). See HOLY ROMAN EMPIRE.

ELECTRA (Lat., from Gk. Ἠλέκτρα). In Greek legend: 1. The daughter of Agamemnon and Clytemnestra, and the sister of Orestes and Iphigenia. While Agamemnon was absent at the siege of Troy, his cousin Ægisthus corrupted Clytemnestra and, on the great leader's return, assisted her in murdering him. Electra, alarmed

for the safety of Orestes (q.v.) and desiring to have in him an avenger, contrived to send him to his uncle Strophius, King of Phocis. There he met Pylades and formed with him the friendship so famed in story. By Pylades Electra was mother of Strophius and Medon. Her experiences are recounted by Æschylus in the *Choëphoroi*, by Sophocles in *Electra*, by Euripides in the three dramas *Electra*, *Orestes*, and *Iphigenia among the Tauri*, by Racine in *Electra*, and by Goethe in *Iphigenie auf Tauris*. Consult the introduction to the edition of Sophocles' *Electra*, by Jebb (Cambridge, 1894). 2. One of the Pleiades, daughter of Atlas and Pleione, and mother, by Zeus, of Dardanus (q.v.).

ELECTRICAL ENGINEERS, AMERICAN INSTITUTE OF. This is a national engineering society, with headquarters in New York, organized in 1884. Its objects are to advance the theory and practice of electrical engineering and the arts and sciences connected with the utilization of electricity. The total membership, Jan. 31, 1914, was 7705, classified thus: honorary, 4; fellows, 432; members, 1009; associates, 6260. Meetings are held monthly in New York, and at various times in 30 principal cities of the United States and Canada where sections are maintained, and at 47 institutions of learning in the United States and Canada where branches have been organized. The institute publishes the *Proceedings* (monthly) and the *Transactions* (annually).

ELECTRICAL MACHINE (from *electric*, from Lat. *electrum*, Gk. ἤλεκτρον, *ēlektron*, amber; connected with ἡλέκτωρ, *ēlektōr*, bright sun, Skt. *arka*, sun, from *arc*, to shine). An instrument which generates electricity by friction or by the inductive action of one set of conductors on another. It is believed that the earliest-known form was that of Otto von Guericke, which is described and illustrated in his work *Experimenta Nova* (Amsterdam, 1672), a drawing from which is reproduced in Fig. 1. It consisted of a ball of sulphur mounted on an axle which could be revolved. The dry hand of the experimenter was placed in contact with the

FIG. 1. VON GUERICKE'S ELECTRICAL MACHINE.

sulphur sphere, which was electrified by the friction thus developed. In Gravesande's *Physices Elementa* (1720) is described an electrical machine where the ball of sulphur is replaced by a hollow glass sphere which is rotated by means of cords or belts connected with a wheel and crank. In this apparatus threads are provided which are attracted to the charged sphere to show its electrification. In 1744 the electrical machine was improved by Bose, of Wittenberg, who introduced a metallic conductor, by means of which the electricity could be conducted from the sphere to the earth and produce a spark on its way. In the same year Winkler, of

Leipzig, devised a machine with a cylinder of glass instead of a sphere and substituted for the hand two pieces of wool or leather to rub against the glass. Subsequent developments in the eighteenth century included devices to rotate the cylinder, collecting combs or conductors with points, the use of amalgam on the rubbing surfaces, and, finally, the substitution of a disk of glass for the cylinder and sphere previously employed.

In its simple form the frictional machine, as these early pieces of apparatus were termed, is shown in Fig. 2. The glass disk is electrified by the friction of the rubber and the silk flaps, and a positive charge on the glass is produced, which escapes at the rings or points to the prime conductor, where it can be used to charge a Leyden jar or perform other experiments, while the negative charge produced on the rubber passes to the ground. Nearly all forms of frictional machines have been rendered

FIG. 2. SIMPLE FRICTIONAL MACHINE.

obsolete and their place taken by influence machines, whose action is far more effective and is less dependent on the dryness of the atmosphere. Of the influence machines which are extensively used, those of Töpler, Wimshurst, and Holtz, with improvements added by other physicists and instrument makers, are the leading types. Their action is based on the principle of the electrophorus (q.v.), where a charged body is used to charge a conductor which is under its influence. If a conducting body is brought near a substance which is electrified and then is touched so that a path of escape is provided for electricity of the same nature as the original charged body, a charge is communicated to the conductor. The influence machine accomplishes this automatically instead of requiring contact to be made with the finger, as in the case of the electrophorus. In the Töpler machine there are two glass plates, one of which is capable of revolution and is provided with a number of pieces of tinfoil attached to its surface, with small buttons of metal in the centre of each, while the other disk is fixed and has cemented to it two pieces of tinfoil, which are termed field plates. A slight charge is given to one of these field plates, and the movable disk is then re-

volved so that when one of its tinfoil disks, or carriers, comes opposite the field plate, it is charged inductively, since contact is made by a brush of fine brass wire which permits the

FIG. 3. WIMSHURST INFLUENCE MACHINE.

escape of the electricity of the same kind as the charge of the field plate. The carrier thus charged then passes the collecting combs, where it communicates to them a portion of its charge, and is then discharged by a neutralizing brush similar to that with which contact was first made and connecting with the field plate, thus increasing its charge. The same process takes place at opposite side of the plates; only the kind of electricity is changed, with the result that the process is continuous. The electricity from the collecting combs passes to Leyden jars, where it is collected. In the Wimshurst machine, which is shown in Fig. 3, both plates are movable, revolving in opposite directions. Each plate carries a series of tinfoil sectors which not only

FIG. 4. HOLTZ ELECTRICAL MACHINE.

serve as carriers of the charges, but also as inducing plates. The brushes and collecting combs possess essentially the same functions as in the Töpler machine. In the Holtz machine, shown in Fig. 4, there are two glass plates, one of

which is solid and mounted on an axle capable of revolution, while the second plate is fixed and has a central opening through which the axle passes, and two windows through which pointed strips of paper project so that they are in contact or nearly in contact with the revolving plate. Below the window on the fixed plate are attached two pieces of varnished paper connected with the points, which serve as field plates, and opposite to these plates on the farther side of the revolving disk are the collecting combs. One field plate is charged by contact with an electrified body, such as a piece of hard rubber, and the electricity of the same kind, in this case negative, is driven from the opposite side of the revolving plate at the combs, leaving the glass plate with a positive charge. The plate thus charged revolves and the charge is brought opposite the field plate on the other side. Here negative electricity is drawn from the combs, leaving that knob of the prime conductor with a positive charge, while a positive charge is also given to the field plate. The inductive effect becomes greater as the disk is revolved, and as a result we have one set of field plates and the combs and conductors opposite them charged positively, while the others are negatively charged. The knobs of the conductors are at first in contact, but after a few revolutions of the disk they may be separated and a series of sparks produced whose length can be increased as long as the difference of potential is sufficient to overcome the air gap.

In a number of these electrical machines plates of rubber or vulcanite are substituted for glass disks; and the effect is also intensified by increasing the number of disks carried on the same axle, together with the combs, conductors, and other appliances. In the best of these machines sparks over a foot in length are obtained. In electrical machines, as in the case of all apparatus where electricity at high potential is used, the greatest care must be observed in insulating the different parts and conductors. Particularly, all glass parts on which the moisture of the atmosphere is likely to settle must be covered with shellac, varnish, or paraffin. Electrical machines are available for many experiments in static electricity, but save for igniting gas jets and for use in electrotherapeutics they have few practical applications in ordinary life. They will be found described in a simple manner in S. P. Thompson, *Electricity. Lessons in Electricity and Magnetism* (New York, 1902). An interesting historical discussion is given in Gerland and Traummüller, *Geschichte der physikalischen Experimentierkunst* (Leipzig 1899). The advanced student may consult with profit the various volumes of the *Annalen der Physik*, and such treatises as M. B. Postels, *Lehrbuch der Physik*, vol. 1 (Brunswick, 1888-90); Wüllner, *Lehrbuch der Physik* (Leipzig, 1895); Gustav Wiedemann, *Die Lehre von der Electricität* (Brunswick, 1882-85). See ELECTRICITY; ELECTROPHORUS.

ELECTRICAL RESISTANCE. See RESISTANCE. ELECTRICAL.

ELECTRICAL UNITS. In order to express by numbers the amounts of the different electric and magnetic quantities, various units or standards of comparison are necessary. They are all based upon the definition of a unit electrical charge and of a unit magnetic pole.

The C. G. S. Electrostatic System starts with the following definition: A unit electric

charge is such a one that, if two particles of matter, placed in a vacuum at a distance of one centimeter apart, are each charged with a unit charge, the force of action of one on the other will be one dyne. Based on this definition are the following units: Two points are at a unit difference of potential if it requires one erg to carry a unit charge from one point to the other. The capacity of a condenser is unity if, when charged to a unit difference of potential, there is a unit charge on each plate of the condenser. A unit current is such that, if it flows for one second, an electric charge equal to unity is carried. On this unit current all the magnetic quantities could be based.

The C. G. S. Electromagnetic System starts with the following definition: A unit magnetic pole is such that, if two such poles are at a distance apart of one centimeter in a vacuum, the force of action of one on the other is one dyne. On this definition is then based that of a unit electric current; viz., it is such a current that, if it is flowing through a linear conductor bent in the form of a circle of radius r cm., the force on a unit magnetic pole placed at the centre of the circle is $2\pi/r$, where, as usual, $\pi = 3.14159$. A unit quantity is, then, the charge carried by a unit current in one second, and to this can be referred units of potential and capacity; a unit electromotive force between two points is such that it requires one erg to carry a unit quantity between them, or if a unit current is flowing between them an amount of energy equal to one erg is set free in one second; a linear conductor of unit resistance is such that, if a unit electromotive force is applied at its ends, a unit current will be produced; a unit of induction is the induction in a circuit when the electromotive force induced in this circuit is unity while the inducing current varies at the rate of a unit current per second.

Experiments have established the connection between the units for the same quantity in the two systems. Knowing this ratio for any quantity, e.g., electric current, it may be at once deduced for the others. It is thus established that

$$\begin{array}{lcl} \text{Electrostatic unit} & \text{Electromagnetic unit} \\ \text{of quantity or current} & = & \text{of quantity or current} \\ \text{of potential or E.M.F.} & = & \text{of potential or E.M.F.} \\ \text{of capacity} & = & \text{of capacity} \div v^2 \end{array}$$

where $v = 3 \times 10^{10}$, or 30,000,000,000, very approximately. This is the same number as that expressing the velocity of light, and should be according to the theory of light, which identifies it with the medium serving for the propagation of disturbances due to electric oscillations. See LIGHT; ELECTRICITY.

These C. G. S. electromagnetic and electrostatic units are, in nearly every case, of inconvenient magnitude for practical purposes; and further, their definitions are not such as lead directly to methods of measurement. Consequently certain so-called practical units have been adopted which are of convenient magnitude and bear simple relations to the absolute units so far as possible. The following are these practical units, as defined at the London Conference of 1908: The unit of resistance shall be what is known as the international ohm, which is substantially equal to 1,000,000,000 units of resistance of the centimeter-gram-second system of electromagnetic units, and is represented by the resistance offered to an unvarying

electric current by a column of mercury at the temperature of melting ice, 14.4521 grams in mass, of a constant cross-sectional area, and of the length of 106.3 centimeters. (This would require a cross section of 1.00003 square millimeters, according to the accepted value for the density of mercury.) One million ohms, i.e., 10^6 ohms, is called a megohm.

The unit of current shall be what is known as the international ampere, which is 0.1 of the unit of current of the centimeter-gram-second system of electromagnetic units, and is the practical equivalent of the unvarying current, which, when passed through a solution of nitrate of silver in water, in accordance with standard specifications (see AMPERE), deposits silver at the rate of 0.001118 of a gram per second. One thousandth of an ampere is called a milliampere.

The unit of electromotive force shall be what is known as the international volt, which is the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of an international ampere, and is practically equivalent to $\frac{100000}{100000}$ of the electromotive force between the poles or electrodes of the cell known as a normal cadmium Weston cell, at a temperature of 20°C , and prepared in the manner described in the standard specification. See VOLT.

The unit of quantity shall be what is known as the international coulomb, which is the quantity of electricity transferred by a current of one international ampere in one second. See COULOMB.

The unit of capacity shall be what is known as the international farad (see FARAD), which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity. One-millionth of a farad is called a microfarad.

The unit of work shall be the joule, which is equal to 10,000,000 units of work in the centimeter-gram-second system, and which is practically equivalent to the energy expended in one second by an international ampere in an international ohm.

The unit of power shall be the watt, which is equal to 10,000,000 units of power in the centimeter-gram-second system, and which is practically equivalent to the work done at the rate of one joule per second. One thousand watts is called a kilowatt.

The unit of induction shall be the henry, which is the induction in a circuit when the electromotive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second. Consult *Circulars* of the United States Bureau of Standards (Washington, D. C.). See HENRY.

ELECTRIC ARC. The effect produced when an electric current is maintained between two electrodes or terminals at a gap or opening in the circuit. This phenomenon involves the production of light and the generation of heat, and consequently the arc is employed for purposes of illumination as well as for producing high temperatures. The arc is distinguished from a spark in that the latter is of extremely brief duration and has a disruptive character, whereas in the case of the arc the vapor produced by the volatilization of the extremity of the electrodes is raised to a high temperature and forms a path across which a continuous discharge takes place. Sir Humphry Davy in 1800 exhibited to the Royal Institution apparatus where a continuous

spark was produced in a gap between two pointed pieces of charcoal, whether they were in air, or in water, or some other liquid. In 1808 Davy, by using a battery of 2000 elements, produced an arc nearly 4 inches in length. In 1843 carbon conductors formed from gas coke instead of charcoal were made use of by Foucault, and later various substances were introduced into the carbons in order to increase the length of the arc and make it more steady.

The first essential of an arc is an electric current of sufficient tension to force its way across the gap or opening where the arc is to be produced. Unless there is a very large difference of potential on both sides of the gap, there must first be contact between the two carbons or other electrodes while the current passes, and then after they have been separated the arc will be produced. As the terminals are separated, a minute spark is produced, and a part of the carbon or other material is volatilized and made into smoke. The heat thus produced is so intense that it is necessary to employ electrodes of a highly refractory material in order to prevent their melting or too rapid vaporization, and it is for this reason that use is made of carbon terminals. The arc can be produced by either an alternating or direct current from a battery or dynamo. A pressure of about 45 volts is required to maintain an arc between carbons in the open air; if the carbons are inclosed so as to prevent the escape of the carbon vapor formed, as in the modern inclosed arc lamps, a pressure of about 75 volts is required. The current varies with the size of the carbons, in commercial practice about 10 amperes for the open arc and 6.5 amperes for the inclosed type. The carbons, when used for lighting, are generally placed vertically one above the other, and the positive carbon is distinguished by the formation of a crater, which is the most brilliant source of light as well as the place of most intense heat, being at a temperature of about 3500°C . (Vielle). The negative carbon takes a pointed shape, but is consumed only one-half as rapidly as the positive. Both carbons are incandescent at their tops, and from these sources considerable light is emitted, though about 85 per cent of the total amount comes from the crater just mentioned. The arc itself furnishes only about 5 per cent, while the remaining 10 per cent comes from the negative carbon. The arc is affected by the magnetic influences, and the bow-shaped arc is produced with vertical carbons by the action of the earth's magnetism. It was from this curved appearance that the arc took its name. Many interesting effects take place in the arc, one of which is the change from carbon to graphite experienced in the electrodes of arc lamps. The composition of the light furnished by the electric arc varies with the material of the electrodes and even with different qualities of carbon. However, the light in general resembles sunlight, but is richer in violet rays. An electric arc formed between carbon electrodes will be found to consist of a central portion of violet hue, which is doubtless the vapor of the carbon rendered incandescent at the crater. Surrounding this is a nonluminous portion where a dark flame indicates that the oxygen of the external air is being combined with the carbon and carbon monoxide produced. Outside of this is a luminous flame where the carbon monoxide is further oxidized and carbon dioxide formed. The character of the arc found between carbon

electrodes impregnated with certain metallic salts—the so-called “arc”—is quite different. In such arc flame itself is rendered intensely brilliant by the luminosity of these metallic vapors, due to the great heat of the arc, and only a very small portion of the light comes from the crater. Such arcs give from three to five times the illumination of an ordinary arc. The color of the light depends on the salts used, but is usually a warm orange yellow. A luminous arc lamp used extensively has an arc between a stationary copper electrode and a lower magnetite electrode. There are also certain substances which can be used as electrodes between which an arc can be established with but a comparatively slight elevation of temperature, but with an arc flame of great luminosity. In this class belong most vacuum arcs, such as the mercury arc, which is the source of light in the Cooper-Hewitt Mercury Lamp. The color of this light is a decided greenish blue, which largely offsets the advantages resulting from the high efficiency of the lamp.

For a description of the mechanical features of the various forms of arc lamps and the apparatus used in the various arc-lighting systems, see the articles on **ELECTRIC LIGHTING**, **DYNAMO-ELECTRIC MACHINERY**, and **TRANSFORMER**. The application of the arc in the production of high temperatures for metallurgical processes is discussed in the article on **ELECTRIC FURNACES**. For a fuller description of the electric arc in reference to practical conditions in electric lighting, see Crocker, *Electric Lighting*, vol. ii (New York, 1901). A popular treatise on electricity, in which some attention is paid to the arc and its phenomena, is *Lessons in Electricity* (New York, 1901). Consult also Ayton, *The Electric Arc* (8th ed., New York, 1908); *American Handbook for Electrical Engineers*, ed. by Pender (New York, 1914).

ELECTRIC DISCHARGE. See **ELECTRICITY**.

ELECTRIC FISH. A fish which possesses the power of discharging electricity at will. Electric organs are well developed in three sorts of fishes: (1) most strongly in the Brazilian electric eel; (2) in a genus (*Malapterurus*) of African catfishes; and (3), most weakly, in the torpedo family of rays. Electric organs are present, but developed to a much lesser degree in some other fishes, which are called pseudoelectric. The organs are modified muscular tracts and nerve connections, by means of which the fish are able to give an electric shock. They lie, in the case of the torpedo, in the head and gill region; in the South American eel they are on the ventral surface of the long tail; and in *Malapterurus* they practically incase the entire body, or occur in lateral lines under the skin on each side of the tail. The electromotive force seems to be under the influence of the central nervous system, and the nerves supplying the organs are enormously developed. In the torpedo the “electric plates” are arranged vertically, and the current passes in the same direction from the lower to the upper side. In the other two they are arranged longitudinally, and the current in *Gymnotus* passes towards the head and in *Malapterurus* towards the tail. The

discharge, when the animal is at its best, may stun an animal as large as the horse. This power is of use, doubtless, in defense and probably in capturing smaller prey.

Electric Eel. This fish (*Gymnotus*, or *Electrophorus electricus*) inhabits the rivers of the basin of the Amazon and Orinoco, wherever they are warm and sluggish. It is in shape like a thick, stout, blackish, scaleless eel, and may grow to be 6 feet long; but it differs so much in structure from ordinary eels that it has been set apart as a separate family, Gymnotidae, allied to the carps and catfish, or silurids. It is abundant and seems to have the general food and habits of an eel, but little is known in regard to its habits or the use of its battery, except that it kills more fish than it can consume. The flesh is filled with bones, but is said to be palatable, and is not only eaten, but is regarded by the native South Americans as having medicinal value.

Electric Catfish. These shock-giving catfish compose the subfamily Malapterurinae, of which the best known is the raash (*Malapterurus electricus*) of the Nile. It lives in all the large rivers of the tropical part of Africa, is sluggish in movement, and lurks in dark places. Its flesh is used as food. It grows to a length of 4 feet, with the ordinary rayed dorsal fin replaced by a fatty dorsal fin just in front of the rounded tail. It is said to give a shock like that from a Leyden jar, which may be communicated by touching the creature with a conductor.

The Torpedo. The electric rays, or torpedoes, constitute a family closely allied to the true rays. They embrace about 6 genera and 15 species of the warmer seas of the world, and 2 species which approach the southern shores of the United States. They have rounded disklike bodies, with powerful tails, and may weigh 80 pounds; swim close to the bottom and are dark-colored above and light beneath, like other fishes of their class. The best-known species is *Torpedo marmoratus* of southern Europe, upon which Dr. Gunther, i. v. of the British Museum, made the following observations: He found that the phenomena attending the exercise of this extraordinary faculty closely resembled muscular action. The power is exhausted after some time, and it needs repose and nourishment to restore it. If the electric nerves are cut and divided from the brain, the cerebral action is interrupted, and no irritant to the body has any power to excite electric discharge; but if their ends be irritated, the discharge takes place, just as a muscle is excited to contraction under similar circumstances. And, singularly enough, the application of strychnine causes simultaneously a tetanic state of the muscles and a rapid succession of the involuntary electric discharges. The strength of the discharges depends entirely on the size, health, and energy of the fish. It seems to be “essential and necessary to them for overpowering, stunning, or killing the creatures [fish of various kinds] on which they feed, while incidentally they use it as the means of defending themselves from their enemies.”

Anatomical Features. The electric organs in all the above-named fishes are to be regarded, according to Wiedersheim, as metamorphosed muscular tracts, and the nerve endings belonging to them as homologues of the motor end plates which are ordinarily found on muscles. As regards the minute structure of the electric organs, the same essential arrangements are met with in

ELECTRIC FISH

1. ELECTRIC EEL (*Gymnotus electricus*).
2. ELECTRIC RAY (*Torpedo marmorata*).
3. ELECTRIC CATFISH (*Malapterurus electricus*).
4. ELECTRIC ORGANS OF TORPEDO: a, polygonal rods.

5. ELECTRIC EEL (*Gymnotus*): a, situation of electric organ (black strip); b, structure of the same, enlarged; c, cross-section of eel's body, showing relative size and position of electric organ (e).

all the forms. The framework is formed of fibrous tissue, which gives rise to numerous polygonal or more or less rounded chambers (see Plate). Numerous vessels and nerves ramify in the connective tissue lying between these compartments, the nerves being inclosed in very thick sheaths and having a great variety of origin, according to the species. In the torpedo they arise from the "electric lobe" of the medulla oblongata, a single branch coming also from the tail in all pseudoelectric fishes, as well as in *Gymnotus*, in which over 200 nerves pass to the electric organ, they arise from the spinal cord. The electric nerves of *Malapterurus* arise on each side from a single enormous nerve cell, which, lying in the neighborhood of the second spinal nerve, is continued into a very large primitive fibre, which passes towards the end of the tail, dividing as it goes.

The end organs in which the nerves terminate are disks, called "electric plates" formed of muscle substance over one or the other side of which, according to the species, the terminal filaments of the nerve spread out. The side of the electric plate on which the nerve branches out is negative at the moment of discharge, while the opposite side is positive, and thus the different arrangements of the parts in *Gymnotus* and in *Malapterurus* render it clear that the electric shock must pass in different directions in these fishes—thus, in *Malapterurus* it passes from the head to the tail, but in the contrary direction in *Gymnotus*. In torpedo the discharge passes from below upward. The mechanism whereby the electric plates become temporarily charged with electricity is not known.

Bibliography. Although the peculiar powers of the torpedo and of the *Gymnotus* were well known to the ancients, the first scientific determination of the electrical character of the shock of the torpedo was by Walsh, in 1772, *Of the Electric Properties of the Torpedo* (Philadelphia, 1773). From that date the electric organs of fishes have been made the object of special study by some of the greatest naturalists and physiologists, among them L. J. M. Spallanzani, who published a special work entitled *Des appareils électriques des poissons électriques* (Paris, 1858), accompanied by a magnificent volume of plates. More recent works are: Boll, *Ueber elektrische Fische* (Berlin, 1874); Sachs, *Untersuchungen am Zitteraal* (Leipzig, 1881); Fritsch, *Die elektrischen Fische* (ib., 1887-90); Schönlein, *Beobachtungen über die elektrischen Fische* (ib., 1897); Lydekker, Cunningham, Boulenger, and Thomson, *Reptiles, Amphibians, and Fishes* (ib., 1912).

ELECTRIC FURNACE. Strictly speaking an electric furnace is an apparatus for bringing about a physical or chemical change in materials by aid of heat obtained from the transformation of electric energy; the term, however, may be extended to include "electrolytic furnaces," in which the action is in part electrothermal, as in the electric furnace pure and simple, and for the rest electrolytic. This class of furnace is mainly employed for the electrolysis of fused salts, as, e.g., in the manufacture of aluminum, where a high heat is necessary to maintain the requisite fusion of the electrolyte.

The limit of heat practically obtainable with the use of ordinary refractory materials is very high, because in the electric furnace the fusing

material is at a higher temperature than the crucible, whereas in ordinary fusion the temperature of the crucible exceeds that of the material fused within it. The maximum temperature practically obtainable in nonelectric furnaces is about 2000° C., whereas a temperature as high as 3500° C. is easily reached and maintained in the commercial electric furnace.

Electric furnaces may be classified according to the method in which the heat is produced, as arc furnaces and resistance furnaces. The arc furnace consists essentially of an electric arc (see ELECTRIC ARC), usually with carbon electrodes inclosed in a chamber made of material which is both highly refractory and a poor conductor of heat, as, e.g., fire brick or chalk. In the resistance furnace the heat is produced by the passage of an electric current through some highly refractory material, as carbon, or some of the rare metallic oxides (such as those used in making the glowers for Nernst lamps), embedded in the wall of the furnace, or the heat may be developed directly in the material to be treated by using the latter as the conductor of the current. A very convenient form of resistance furnace is the so-called "induction furnace"; in this furnace the resistance element, either the furnace charge or some auxiliary material, instead of being connected directly with the circuit supplying the current, forms the secondary of a transformer (see TRANSFORMER); a small current at a comparatively high voltage in the primary of many turns induces the necessary large current at low voltage for heating the material to be treated, which forms a single turn secondary.

Electric furnaces are used chiefly in the manufacture of aluminum, calcium carbide, carborundum, graphite, phosphorus, special grades of iron and steel, and ferromanganese. (See ELECTRO-CHEMISTRY, INDUSTRIAL.) One of the simplest industrial applications of the resistance principle is found in the Acheson furnace used in the manufacture of carborundum. The furnace consists of a trough built up of loose bricks, with massive electrodes made up of a bundle of carbon rods projecting through the end walls. Between these electrodes lies a core of granular carbon, coke, or carbon rods. Around this core is packed a mixture of powdered coke, sand, and a small quantity of sawdust and common salt. The electrodes are then connected with the source of electric energy, and the proper current maintained flowing through the core to raise the temperature of the mixture of coke and coke to the point required for the combination of the silicon and carbon. In the furnaces used at Niagara this conversion takes about 36 hours. These furnaces are 15 × 7 × 7 feet. The electrodes consist of bundles of 60 3-inch carbon rods, each 2 feet long. The coke resistance core is 9 feet long by 2 feet in diameter. The power required to operate such a furnace is about 1000 horse power, or an energy consumption of approximately 4 kilowatt hours per pound of carborundum.

The most widely used types of arc furnace are those of Heroult, Stassano, and Girod. Each consists of a shallow refractory chamber mounted on a tilting rig. Through the roof of this chamber extend one or more large electrodes of carbon or graphite, from which an electric arc of great power is formed. The Heroult furnace is usually operated three-phase (see DYNAMO-ELECTRIC MACHINERY) and has three

electrodes between which a triple arc is formed above the surface of the molten charge. The Girod furnace is usually employed and employs a single carbon electrode and molten charges serving as the lower electrode. The Heroult furnace is built in capacities up to 15 tons, the Girod furnace up to 12 tons, and the Stassano, now little used, up to 5 tons. All arc furnaces are subject to a marked disadvantage, viz., that the electrode material has a contaminating effect on the molten metal and renders difficult the refinement of steel to a precise quality.

The induction furnace consists of a ring-shaped hearth built of refractory brick and inclosed by a refractory cover which may be removed for charging purposes. This ring is linked by one or more upright transformer cores, built up of sheet-iron laminations. On these cores are wound coils of copper wire having a large number of turns, which are supplied with current from some alternating-current source. The metallic charge in the hearth forms a secondary circuit for these coils, and in it an enormous current of low voltage is induced by step-down transformer action. The flow of this current through the resistance of the metal mass causes it to give up its energy in the form of heat and raise the metal to a high temperature. The types of induction furnace in greatest use are the Kjellin and the Röchling-Rodenhauser. The former is a single-phase furnace, built in capacities up to 8.5 tons and supplied with alternating current of low frequency, usually from 5 to 15 cycles per second. The generation of single-phase currents of such low frequency requires special and expensive equipment. The Röchling-Rodenhauser furnace is of the three-phase type and is well adapted to standard commercial frequencies and generating apparatus. It is built in sizes up to 15 tons.

The accompanying table gives the approximate number of kilowatt hours of energy required for each ton of product with various initial charges:

Pig iron from ore, 2000 kw. hr.
Steel from ore, 3000 kw. hr.
Steel from cold pig iron, 1500 kw. hr.
Steel from cold scrap iron, 1000 kw. hr.
Steel from cold scrap iron and scrap, 600-1000 kw. hr.
Steel from cold scrap, 600-900 kw. hr.
Refining low-carbon steel into special grades of steel, 120-300 kw. hr.

In general, the commercial use of electric furnaces is limited to those processes where a specially high temperature is required, or where the substances under treatment must be maintained in a pure state; and then only when electric power can be obtained at a comparatively low cost, as, e.g., in localities where there is an abundant supply of water power. Its greatest field is in the refining of common grades of iron and steel into special steels of greater uniformity than can be produced by the usual processes. Consult: Wright, *Electric Furnaces and their Industrial Applications* (New York, 1905); Moissan, *Le four électrique* (Paris, 1897); Stansfield, *Electric Furnace* (New York, 1914); Rodenhauser and Schoenawa, *Electric Furnaces in the Iron and Steel Industry* (ib., 1913); *American Handbook for Electrical Engineers*, ed. by Pender (New York, 1914).

ELECTRIC FUZE. See FUZE.

ELECTRIC GENERATOR. See DYNAMO-ELECTRIC MACHINERY.

ELECTRIC HEATER. Electric heaters con-

sist essentially of coils or circuits of some refractory metal through which the current is passed, these coils or circuits being surrounded by air or some insulating material, and the whole being placed in a metallic box or radiator, which throws off or radiates the heat produced. In the simplest form of electric heater exposed coils of wire or strips of metal are wound around insulating material or left surrounded by air. Another common form consists of wire or strips of metal embedded in asbestos, either in the form of coils or in flat layers. A third class of heater is made by embedding the resistance wire in some fireproof insulation, such as enamel or glass. The Tommasi heater consists of a coil of wire embedded in a material having great latent heat of fusion, such as crystallized acetate of sodium and hyposulphite of sodium. In these heaters the current is turned on until the desired temperature has been reached, and is then turned off and the latent heat allowed to dissipate itself. It is claimed that the heater remains active about four hours after the current is shut off. The Prometheus system consists of a broad strip of rare metal fused on to an enamel which forms the outside of the vessel, and the current is passed through the metal strip or film. In the recent forms of this heater the heating films of gold or platinum between mica sheets are used. In some cases an efficiency as high as 95 per cent can be obtained. The Le Roy system consists of inclosing sticks of crystallized carbon in glass tubes. In the Parville heater there are rods of metallic powder mixed with fusible clay, compressed under a pressure of 2000 kilograms per square centimeter and baked at a temperature of 1350° C. Unless electricity is produced at a very low cost, it is not commercially feasible for heating residences or large buildings. In the electric heater can be used for heating small offices, bathrooms, waiting rooms, for heating electric cars, etc. For heating laundry irons it is commonly figured that electrically heated and gas-heated irons are on a par in economy when gas costs one dollar per 1000 cubic feet and electricity costs one cent per kilowatt hour. The efficiency of electric cooking apparatus varies from 60 per cent to 90 per cent (for ovens), depending upon a number of variable conditions, such as time, size, quantity to be heated, and temperature rise. Of the total energy given off by burning a pound of coal in an ordinary cooking stove, only about 2 per cent is effective in the actual process of cooking, 12 per cent being wasted in obtaining a glowing fire, 70 per cent going in the chimney, and 16 per cent being radiated into the room. The efficiency of a gas stove is much greater, for some operations being as high as 20 per cent; but for ordinary cooking 15 per cent is a fair average. The most economical system for cooking or heating is not necessarily the one that has the highest efficiency; the cost of the particular form of energy must also be considered. In New York, in 1914, one dollar would buy 11 kilowatt hours of electric energy, 1333 cubic feet of gas, or 301 pounds of coal. Eleven kilowatt hours are equivalent to 9427 heat units; when burnt under suitable conditions, 1333 cubic feet of gas are capable of rendering 227,000 heat units; 301 pounds of coal burnt in an ordinary range will yield about 2,900,000 heat units. The

number of effective heat units in each case will be proportional to the efficiency of the respective types of stoves; for the electric oven at 85 per cent efficiency, 8012 heat units; for the gas stove at 15 per cent efficiency, 34,050 heat units; for the coal stove at 2 per cent efficiency, 58,000 heat units. For the same results electricity costs about seven times as much as coal and four times as much as gas. The advantages possessed by electric heaters as regards cleanliness and convenience, however, in many cases offset their lack of economy, and there are in use at present numerous devices, such as electric irons, broilers, chafing dishes, warming pads, and small radiators; in some places where electric power is cheap, even whole kitchen and laundry outfits have been installed. In a gas stove, considering the number of heat units obtainable at a certain price to be small compared with solid fuel, the ventilating current required for the operation alone consumes at least 80 per cent of the heat units obtained by burning the gas. In an electrical oven more than 90 per cent of the heat energy can be utilized; and thus, although 5 to 6 per cent only of the heat energy of the fuel is present in the electrical energy, 90 per cent of this, or $4\frac{1}{2}$ per cent of the whole energy, goes into the food. ELECTRIC HORN, IN MOTOR VEHICLE.
See MOTOR VEHICLE.

ELECTRICITY. Few sciences can claim as great an antiquity as that of electricity. It is believed that Thales of Miletus (c.640-546 B.C.) knew that amber, after being rubbed, acquired the property of attracting light bodies; and Theophrastus (c.372-287 B.C.), in his treatise *On Gems*, mentions the fact that this power is not peculiar to amber. No definite scientific information was acquired, however, until the close of the sixteenth century. William Gilbert (q.v.) published in 1600 his great work *De Magnete*. In this book he used for the first time the terms "electric force" and "electric attraction," and distinguished between "electrics" and "non-electrics"—the former name being given to bodies which act as amber does when rubbed; the latter to bodies, such as metals, which, when held in the hand and rubbed, do not acquire the power of attraction. He clearly distinguished between magnetic and electric action, as Cardan (1501-76) had also done before, but in an imperfect manner. Robert Boyle, Sir Isaac Newton, and others made many interesting observations on electrical phenomena, the former showing that electric attraction takes place through a vacuum. Otto von Guericke, the inventor of a rude form of electrical machine (q.v.), also discovered electric induction, the phenomena of which were studied with special care by Canton nearly a century later. Hawksbee made several important advances, being the first to show how to electrify metals by rubbing, and also the first to observe that electric charges are only on the surfaces of metals, not in the interior.

During the eighteenth century electric phenomena were studied very extensively, especially towards its close, when means of producing electric currents were discovered. Stephen Gray (q.v.), in the early part of the century, observed the important fact that electric forces could be carried for a considerable distance by means of

packthread and other bodies, thus discovering electric conduction, and he was then led to distinguish between conductors and nonconductors. The possibility of two kinds of electricity—vitreous and resinous, or positive and negative—was established independently by Du Fay in France and Kinnersley in Philadelphia. The former developed also a two-fluid theory of electricity which persisted for many years. The Leyden jar was discovered by accident in 1745, and from this time on public exhibitions of electric phenomena were most popular. Most interesting and important work was being done also in America by Benjamin Franklin (q.v.) and a group of his friends. He proposed a one-fluid theory, which after more than a century of neglect has reappeared as a possible explanation of the new phenomena—“corpuscles” and ions. Having notice of points on conductors in discharging bodies and believing that lightning was an electric phenomenon, Franklin, in 1750, proposed an experiment to test his theory. It was to extend a long pointed wire upward from a steeple and to see if electrical charges could be observed at the lower end of the wire when a thundercloud passed overhead. The actual experiment was carried out according to these directions in 1752, in France, by Dalibard, and later by Delor, and in the same year Franklin performed his famous kite experiment. Soon after this lightning rods, which had been suggested by Franklin, became popular both in America and Europe. The main phenomena of electricity were discovered by Epinus, about 1770. Many of the most important facts in electricity which were made known during the nineteenth century by Coulomb, Ohm, and Faraday were in reality discovered by Henry Cavendish (1731-1810), one of the world's greatest philosophers. He showed that the capacity of a condenser varied with its size and with the nonconductor used; he studied the conducting power of solutions; and he also discovered what is now called Ohm's law. He saw, further, from mathematical considerations, that if electrical charges act on each other with a force varying directly as the amounts of the charges and inversely as the square of their distance apart, then a charged conductor must have its charge entirely on its surface; whereas, if the law of action were different, there would be some charge on the interior. By a most ingenious experiment, performed before 1773, he showed that, to the limit of accuracy of his apparatus, there was absolutely no charge on the interior. These electrical papers of Cavendish were not published until 1879, when they were edited by Clerk-Maxwell. The law of electric action was proved independently and in a less accurate manner by Coulomb (q.v.) in 1785.

Many improvements in electrical apparatus were made; a circular glass plate and a rubber cushion coated with a tin amalgam were substituted for the sulphur globe and the hand as used by Von Guericke. The gold-leaf electroscope was invented in 1786 by Abraham Bennet and was improved by Volta (q.v.). The latter also, in 1775, invented the electrophorus.

In 1780 Galvani (q.v.) made the historic observation in regard to the twitching of the frog's legs, which was followed by the discovery in 1794, by Volta, of the correct explanation. This led at once to the invention of the so-called voltaic pile and voltaic cell, a description of

which was communicated by Volta in a letter to Sir Joseph Banks, written March 20, 1800. Means were thus furnished for "electric currents." Within a few years, the letter Nicholson and Carlisle in England constructed a pile and by means of it observed and studied the decomposition of water.

The progress of the science of electricity during the nineteenth century was so rapid that it is impossible to do more than to note the most important steps. The investigation of the action of an electric current when passed through liquids was continued by Sir Humphry Davy (q.v.) and Michael Faraday (q.v.), to the latter of whom is due the statement of the laws of electrolysis. The theoretical explanation of the phenomena is the work of Grothuss, Faraday, Hittorf, Clausius, and Arrhenius. Improved cells for the production of currents were made by Sturgeon, Daniell, Grove, Bunsen, and others. So-called "storage" cells, or secondary cells, were first described by Ritter in 1803 and were improved by Planté and by Faure.

In 1819 Oersted discovered the magnetic action of an electric current, and the exact mathematical laws stating the action of a current upon a magnet and of one current upon another were deduced by Biot and Savart (1820) and by Ampère (1821).

Arago and Davy (1820) discovered independently that a current passed through a helical conductor magnetized a steel needle placed inside. Sturgeon, in 1825, made the first electromagnet, using a single helix of wire wound round a bar of iron shaped like a horseshoe, varnish being used to insulate the coils of the wire. Joseph Henry (q.v.) showed how this magnetic action of a current could be increased. He insulated the wire by means of silk cloth and wound it in layers like thread on a spool. By means of an electromagnet made on this principle Henry constructed a telegraph instrument.

The "static needle" was invented by Schweigger in 1820; the "static needle" by Nobili in 1825; but the modern forms of the instrument are due to the genius of Lord Kelvin. The phenomena of thermoelectricity were discovered by Seebeck in 1821; the Peltier effect, in 1834.

The discovery of induced currents was made independently by Henry and Faraday in the years 1829-31; and the latter described the principle of the dynamo which has been perfected in recent years by Wilde, Siemens, Gramme, and countless others. The first induction coil was made by Charles Page, of Washington, D. C., in 1838. In 1842 Henry proved that the discharge of a Leyden jar was oscillatory—in which he had been anticipated by Savary (1827)—and discovered the existence of waves in the ether produced by such a discharge. The mathematical theory of the discharge was given by both Kelvin and Helmholtz, and that of the waves by Clerk-Maxwell. The "laws" of the waves were investigated by Hertz in 1888, and more recently by Marconi and others, who have made commercial use of them.

To Faraday is due the realization of the importance of the properties of the nonconducting media separating charged bodies. He proved that both electrostatic and magnetic actions take place *through* the media, not "at a distance." He introduced the idea of lines of force, and the laws; he also showed that the attraction and repulsion of bodies caused by electrical or magnetic forces are due to the

relative properties of these bodies and of the surrounding medium. Clerk-Maxwell expressed Faraday's experimental discoveries in mathematical language and formulae and advanced the theory of electricity and magnetism which is the basis of all modern theories.

The idea of expressing all electrical and magnetic quantities in absolute units, based on some definite system of standards of length, time, and mass, is due to Gauss (q.v.) and Weber (q.v.).

The most important recent advances in the knowledge of the connection between electricity and matter have come through the observation of the ionization (q.v.) of gases. Most of the researches along this line have been made under the direction of Prof. J. J. Thomson, at the Cavendish Laboratory, Cambridge, England.

To understand the fundamental principles of electricity, it is well to start with the experiments that were performed by the early Greeks.

Here it is found that, if two bodies are brought into intimate contact, e.g., by pressure or by rubbing together, and then separated, they have certain new properties, the most marked of which is the power of attracting any small bits of matter, such as particles of dust or fragments of paper. Bodies possessing this power are said to be "charged with electricity." It is found, however, that if certain bodies, such as glass, rubber, silk, are charged, the electrical effects are manifested only at the points where the contact was made with the other body; while with other bodies, such as pieces of metal, the electrical effects are manifested over the whole body regardless of where the contact was made, and the charge is said to spread over the surface. Bodies of the latter kind are called "conductors"; of the former, "nonconductors." It takes time—infinitesimally short—for a charge to distribute itself over the surface of a conductor; but in the end, unless there is further charging, conditions come into a steady state; the charge is said to be at rest. The science of the study of the other properties of electrical charges at rest is called "electrostatics," while the study of the phenomena involved in varying and moving charges belongs to "electric currents," or "electrokinetics."

ELECTROSTATICS

Fundamental Phenomena. As said before, the primary fact of electricity is that, when two bodies are brought in contact and then separated, they acquire the power of attracting small portions of matter. Further, the two bodies which are thus charged attract each other, as may be shown by suspending one so that it is free to move and bringing the other near it. If other portions of matter are charged, e.g., pieces of rubber, of dry wood, of cotton cloth, of paper, of fur, it will be observed that, when they are brought near a suspended glass rod which has been charged, there are some cases of attraction and others of repulsion. All charged bodies which attract a piece of glass charged by contact with silk are said to be "negatively" charged; and all bodies which repel the charged glass are said to be "positively" charged. It is found by experiment that any positively charged body will repel any other body positively charged; any negatively charged body will repel any other negatively charged body; any

negatively charged body will attract any positively charged body.

It is found that glass rubbed with silk is positively charged, but if rubbed with cat's fur it is negatively charged. It is possible to make a tabular arrangement of bodies in which any body when charged by contact with any other body lower down in the series becomes positively charged, the second body becoming negative. Such a table is called the "electrostatic series"; a few of its members are the following: cat's fur, glass, paper, flannel, silk, cork, metals, ebonite, sealing wax, sulphur, hard rubber.

As noted above, natural bodies may be divided into conductors and nonconductors; conductors being such bodies as allow charges to spread over them, while nonconductors keep the charges localized where the contact took place—a "charge" meaning simply a condition at the surface of a body such that there are forces of attraction or repulsion manifested there on other charged bodies or on light pieces of matter. Among the conductors are: all metals, water, some salt or acid in solution, damp human body, the earth. Glass, sulphur, paraffin, dry wood, silk, paper are nonconductors or insulators. Thus, if a piece of metal is held in the hand when it is charged, the charge will distribute itself over the metal, the hand, and body, and sometimes over the floor if it is not dry; and therefore the charge left on the metal itself may be extremely small. It is necessary, then, in order to charge the metal strongly, to hold it in a piece of paper or other nonconductor. Charges may be transferred from a charged body to an uncharged one simply by allowing their surfaces to touch. If a charge is given a conductor and allowed to come to rest, it is found to be entirely on the surface, not in the interior. Thus, there are absolutely no electrical forces *inside* a hollow, closed conductor which is charged, unless a separate charge on a different body is placed inside.

If a charged body is brought near an uncharged one which is separated from the earth by a nonconductor, i.e., is "insulated," electrical forces may be observed near the latter of the two bodies; it is said to be charged by "induction." If the body which was originally charged was positive, the portion of the other body which is nearest it is now negatively charged, and the portion which is farther away is positively charged. Exactly the reverse is true if the body which was originally charged is negative. If the charged body is now removed to a distance, the "induced charges" will disappear. If the body which was originally uncharged is joined to the earth by a conductor, and if, after the charged body is brought near, this conductor is removed, the former body will be found to be charged; and this charge will now remain even when the originally charged body is removed. To join a conducting body, e.g., a metal sphere, to the earth by a conductor is most simple; it is necessary to join it by a wire to a gas or water pipe: but to connect a nonconducting body, e.g., a glass sphere, to the earth is not at first sight so easy; it can be done, however, by holding a Bunsen burner so that the flame spreads over the whole surface of the body, because the gases in the flame are good conductors. In both cases it is evident that the action of the connecting conductor is to make the earth itself a portion of the originally uncharged body; and so the induced

charges are distributed, one on the earth and one on the body itself. This last is of a kind opposite to that of the body which originally was charged, and it remains after the connection with the earth is removed.

There are thus three methods of charging a body: (1) by contact with another body and then separation; (2) by contact with another charged body; (3) by induction as just described. The fact that, when a charged body is brought near an uncharged one, there are charges induced on the latter, of such a kind that an unlike charge is nearest the former, accounts for the observed attraction of small particles of matter by charged bodies. It should be noted particularly, however, that the forces of attraction or repulsion between charged bodies vary greatly with the nature of the surrounding medium, being greater in air than they would be in pure water; and the character of the induced charges and the question of attraction or repulsion depend upon the *relative* properties of the surrounding medium and the body on which the induced charges are. The importance of the consideration of the surrounding medium was first emphasized by Faraday, who gave the name "dielectric" to the material medium around charged bodies, because the electrical actions evidently take place through it. All nonconductors can serve as dielectrics, and so can certain poor conductors under certain conditions. It will be shown later that the potential energy of charged bodies depends directly upon certain properties of the dielectrics in the neighborhood; and whenever any motions of attraction or repulsion take place, they are always such that by the change the potential energy is decreased.

A special case of induction which is of great theoretical and practical importance is one due to Faraday and called the "ice-pail experiment," because first performed with a metal ice pail. If a positively charged body, suspended by an insulating cord, is lowered carefully into a nearly closed hollow conducting vessel which is insulated from the earth, in such a manner as not to touch the vessel, positive charges may be observed on the outside of the latter. These charges do not change in any way, however the charged body inside is moved about. If this body is removed without having touched the vessel, the charges on the latter disappear. Similarly, if a negatively charged body had been lowered into the vessel, negative charges would have appeared on the outside. Now, if a charged body, together with the other body with which it was originally in contact and so electrified, is lowered into the vessel, there is no effect on the outside of the latter; the action of one charge neutralizes that of the other; they are said to be of "equal quantity," but of opposite sign. Thus whenever a positive charge is produced, an equal negative charge appears also. In the first experiment, therefore, with the hollow conducting vessel, when a positive charge appears on its outer surface, there must be an equal negative charge on its inner surface, which is nearer the positively charged body lowered in from above. If this last body is a conductor, and if it is allowed to touch the hollow conducting vessel, thus forming part of the conductor, two things may be observed: (1) there are no longer any charges inside, everything is discharged; (2) the charges on the outer surface have not changed at all, either in intensity

or position. This experiment proves, therefore, that the positive charge lowered into the vessel induces an *equal* negative charge on the inside of the vessel and an equal positive charge on the outside. The series of experiments shows, further, that the region outside a closed conductor is unaffected by any production or motion of charges inside. It has been stated before that a charged conductor has all the charge on its outer surface unless a charge is separately introduced inside; so, if charges are moved outside a hollow closed conductor, there will be no electrical forces inside. Therefore a closed conductor separates space into two quite distinct portions.

Law of Electrostatic Action. In order to give a numerical value to an electric charge various steps are necessary: 1. Two charges are defined to be equal if they produce the same effect of attraction or repulsion on any third body; in particular, if the two together produce no action, one is equal and opposite to the other. 2. A unit charge is defined to be such that, if two particles of matter have each a unit charge and are at a distance of one centimeter apart in a vacuum, the force between them is one dyne. 3. If two or three or four, etc., unit charges are given a body (e.g., by lowering them into a hollow closed conductor), it will exert a force two or three or four, etc., times that which it would if it had a unit charge. To give a numerical value, therefore, to any charge, it is necessary to find that combination of unit charges—either multiples or fractions—which has the same action on any third body as does the charge for which a number is desired. The number of these unit charges gives the numerical value sought. If, now, two particles of matter are electrically charged, one with a quantity e , the other with a quantity e' , and if they are at a distance apart of r centimeters, the mechanical force of attraction or repulsion is found by experiment to satisfy the law that "the force varies as the product ee' and inversely as r^2 ." In symbols, the force

$$f = \frac{ee'}{Kr^2},$$

where K is simply a factor of proportionality and is a different constant for different dielectrics. In particular, by the definition of a unit charge, if $e = e' = 1$ and $r = 1$, f must equal one dyne if the medium is the pure ether; and therefore on this system of units $K = 1$ for the ether of space free from matter. This system, based on the above definition of a unit charge, is called the "C. G. S. electrostatic" system. (The "dimensions" (q.v.) of an electrical charge may be found at once from the above formula. e and e' are both charge; and hence a charge has the same dimensions as the square root of Kr^2f . Force has the dimensions MLT^{-2} ; therefore the dimensions of a charge are $(KML^2T^{-2})^{\frac{1}{2}}$, or $M^{\frac{1}{2}}L^{\frac{1}{2}}T^{-1}K^{\frac{1}{2}}$. Until something is known of the nature of K , there can be no mechanical understanding of an electrical charge.) That portion of this law of electrostatic action which says that the force varies as ee' and inversely as r^2 is known as "Coulomb's law." It has been tested experimentally in two ways: one directly, by placing charges at different distances; the other indirectly, for it can be proved mathematically that only if this law is true will there be no electrical force inside a closed hollow con-

ductor, e.g., a spherical shell. Coulomb (1785) applied the first method, which is not accurate; and the second was used by Cavendish (1773) and later by Clerk-Maxwell. The fact that the force depends upon the medium was discovered by Cavendish (about 1772), and later independently by Faraday who thoroughly investigated the subject.

Electric Potential. In the neighborhood of any charged body forces are noticed if other charges are brought near or moved about; it is said to be surrounded by a "field of force." The "direction" of the field at any point is defined as that in which a particle of matter positively charged would move if placed at that point and left free to move. If a line is drawn such that at each of its points its direction gives that of the field, it is called a "line of electric force." Such a line evidently starts from a positive charge and ends on a negative one; there is therefore no line inside a closed conductor owing to its charge. Further, these lines are perpendicular to the surface of a charged conductor; for, if they were not, there would be a component of the force in the surface itself and consequently there would be motion of the charges, because a conductor is such a body that there is no opposition to a force tending to move a charge; and this would be contrary to the assumption that the charges are at rest.

The work required to bring a particle with a unit positive charge from the surface of the earth to any point in the field of force round a charged body is called the "electric potential" at that point. (The earth is taken as the starting point because it is a huge conductor whose electric condition may be assumed to be steady; and this definition of potential is equivalent to defining the potential of the earth as being 0. Potentials are measured with reference to that of the earth, just as temperatures on the centigrade scale are measured with reference to that of melting ice.) If one point has a higher potential than another, it requires work to carry a unit positive charge from the latter point to the former; and, conversely, a force must have been overcome; in other words, lines of force always pass from points of high to points of lower potential. It is evident, further, that the potentials of all points of a charged conductor and of all points inside are the same. Therefore the motion of a positive charge is always from high to low potentials, and that of a negative charge is in the opposite direction.

If a positive charge is separated from a negative one by some medium such as air, glass, or paper, and if the charges are large, the difference of potential between any two points of the field which are close together will also be large, and there will be a strong force tending to move positive and negative charges in opposite directions. This force may become so great that there is a rupture of the material medium, air, glass, or paper, and a "spark" is seen. The principal action in the spark is to make the medium conducting; and so the positively and negatively charged bodies are joined by a conductor and totally or in part discharged. There are other effects of the spark, notably the thermal and luminous ones. Two conductors of similar shape, separated from each other by a thin layer of dielectric, form what is called an "electric condenser"; because, if one is charged positively and the other with

an equal quantity of negative electricity, the potential of the former is lower than it would be if the latter conductor were absent, and therefore it can be charged with a greater quantity, with less danger of sparks passing off to the earth and thus discharging it.

Common forms of condensers (see CONDENSER) are parallel plates of tin foil separated by glass or paraffined paper, coaxial cylinders, etc. One of the most familiar types is the "Leyden jar," which consists of a glass bottle coated inside and out, except near the opening, with tin foil.

It is observed that, if a conductor is charged which has sharp points, the charge rapidly disappears. This is owing to the fact that the fall of potential from the conductor into the air is most rapid at the points, and thus minute sparks pass off to the air, giving charges to the particles in the air which are then repelled. Similarly, if a charged body is brought near an uncharged insulated conductor which has sharp points turned towards the charged body, the latter is attracted to the conductor. Those on the side near the charged body pass off the points, are carried across, and discharge the former, leaving a charge on the conductor of the same kind as that on the body which was originally charged.

Capacity. If the charge on an isolated conductor is increased, so is its potential, because more work would be required to bring up a unit charge; if the charge is doubled, so is the potential. In other words, the charge equals a constant times the potential. If e is the charge and V the potential, $e = CV$. This constant C depends naturally on the shape and size of the conductor and on the surrounding dielectric; it is called the "capacity" of the conductor. Similarly, if a condenser is charged with $+e$ and $-e$, and if the potentials of the two conductors are V_1 and V_2 , there will be a constant relation between e and $V_1 - V_2$, which may be expressed $e = C(V_1 - V_2)$. This constant C depends upon the shape, size, and distance apart of the two conductors and on the nature of the dielectric which separates them; it is called the "capacity of the condenser." It was first observed by Cavendish and later by Faraday that the capacity of a condenser was different for different dielectrics, e.g., air, glass, etc. Thus, if the same charge is given two condensers which are identical except in that one has air for its dielectric and the other glass, it is observed that the difference of potential is greater in the former than in the latter, thus showing that the capacity of the latter is the greater. The ratio of the two capacities was called by Faraday the "specific inductive capacity" of the glass with reference to air. If, instead of using air as the dielectric, there had been a vacuum, the ratio of the capacity of the glass condenser to the vacuum one would be a constant which is characteristic of glass and is called its "dielectric constant." It can be shown easily that this constant is the K which occurs in the formula for electric action. K is said to measure the "inductivity" of the dielectric.

It may be proved from mathematical reasoning that the capacity of an isolated sphere of radius R in a medium whose dielectric constant is K is KR ; the capacity of a condenser of two parallel plates of area A and at a distance apart d with a dielectric of constant K is $KA/4\pi d$; etc.

Energy. Since, when a body is charged by bringing it in intimate contact with another body, e.g., glass with silk, and then separating them, one is charged positively and the other negatively, it requires work to pull them apart. The electrical separation therefore has an amount of energy equal to this work. This energy is present as a *strain* in the ether and dielectric which surround the charged bodies, as is shown by the fact that, if the charges are too great, the dielectric is ruptured—a spark passes. Since charges are always on the surfaces of conductors, it is evident that the material of a conductor yields to whatever stresses accompany charging and so cannot be under a strain. Faraday has shown that the strain in the dielectric is of the nature of a tension along the lines of force and a pressure at right angles to them. If a condenser has a charge $+e$ and $-e$, and a difference of potential $V_1 - V_2$ between the conductors, the process of charging may be imagined as having begun when there was no charge (and therefore no difference of potential), and that minute quantities of positive charges were carried from one plate to the other, leaving therefore equal amounts of negative on the first plate. In this way the charges will gradually grow to $+e$ and $-e$, and the difference of potential will increase at the same rate from 0 to $V_1 - V_2$, the average difference being therefore $\frac{1}{2}(V_1 - V_2)$. The difference of potential between the conductors at any instant is by definition the amount of work required to carry a unit positive charge from one plate to the other; therefore, since in the process of charging the condenser a quantity of positive charge e has been carried across at the average difference of potential $\frac{1}{2}(V_1 - V_2)$, the work required is e times $\frac{1}{2}(V_1 - V_2)$. In other words, the energy of the charged condenser is $W = \frac{1}{2}e(V_1 - V_2)$. Expressed in terms of the capacity, $C = \frac{e}{V_1 - V_2}$, this becomes $W = \frac{1}{2}e^2/C$.

It has been shown that C varies directly as K , the dielectric constant, which is greater for glass or paper than for air; therefore, if in an air condenser the air could be replaced by glass or paper, keeping the charges unchanged, the energy would be diminished. It follows then that, since changes take place in nature in such a way as to decrease the potential energy, the paper or glass would be "attracted" in between the charged conductors. All cases of electric attraction and repulsion may be explained in a similar manner.

Electric Oscillations. If an isolated conductor is charged, there will be a definite distribution of charge over the surface in such a manner as to satisfy the law of electric action; but if another conductor is brought near it, the distribution will be altered by the new forces due to induction. If now this second conductor is suddenly removed, or if the forces of induction are suddenly destroyed, the charge will return to its original distribution. Before doing so, however, there will be what may be called "electric oscillations"; i.e., if the $+$ charge has been drawn towards one end of the conductor by the forces of induction, then, when these are removed, it will appear at the farther end, next return towards the first end, etc., gradually coming to its state of equilibrium. These oscillations are extremely rapid and generally die

away very quickly. The simplest mode of producing electric oscillations is to bring close together two conductors and charge them oppositely until a spark passes; this has the effect of joining them with an extremely good conductor. It may be shown that, as a result, the conductor which was charged positively becomes negatively charged, then positively, etc., each successive charge becoming less and less, until finally equilibrium is reached. This is what happens in general when the two conductors forming a charged condenser, e.g., the two coatings of a Leyden jar, are brought so close together that a spark passes. (The analogy to a vibrating pendulum slowly coming to rest is complete.) As a result of this oscillatory discharge, the energy of the charges disappears, it being spent, in part, in producing disturbances in the surrounding dielectric of the nature of waves. These waves are in the ether and have identical properties with those which affect the sense of sight or temperature, being, however, longer, i.e., of a smaller wave number. They do not appeal to any human senses, but may be detected by various physical means. See WIRELESS TELEGRAPHY; COHERER.

Electrical Instruments. Electric charges may be produced by various machines which render the processes of charging by contact or by induction continuous and automatic. The commonest forms are the frictional machine (see ELECTRICAL MACHINE) and the electrophorus (q.v.), the induction machine.

Instruments have been devised to measure difference of electric potential both absolutely and relatively. They are called electrometers and are described under that title elsewhere. See ELECTROMETER.

Faraday Tubes. A convenient mode of demonstrating electric phenomena is due to Faraday, who pictured the electric field around charged bodies as filled with tubes whose sides were made by lines of force. These tubes join positive with negative charges and are chosen of such a cross section that, where they meet a charged surface, the open end of each tube incloses a unit charge. The tube will have in general a varying cross section, depending on the paths of the lines of force, and where the electric force is the greatest the tubes are most numerous.

ELECTROKINETICS

Fundamental Phenomena. If a charged electrical condenser is discharged by joining its two conductors or "plates" by a long wire, it is observed that there is no effect, but that the charges disappear and there are certain phenomena in and near the wire. The temperature of the wire is raised; and a magnet suspended, free to turn, near the wire and parallel to it, will be deflected so as to tend to stand at right angles to it. In special cases other phenomena may be observed. The whole phenomenon is described by saying that an "electric current" has passed through the wire, in the direction from high potential to low, carrying the quantity of electricity e , where $+e$ and $-e$ were the charges on the condenser. In this statement there are three definitions: that of "electric current," "direction of the current," and the "quantity carried by the current." The two effects of the current noted are: (1) heating effect in the conductor; (2) magnetic action on a suspended magnet. These actions are

observed with all electric currents; and other additional effects are obtained when the current is not steady. It should be noted, further, that, if the direction of the current in the wire is reversed, the heating effect is as before, but the magnet is deflected in the opposite direction. This furnishes an easy method of determining the direction of the current in the conductor. If charges can be supplied to the terminals of the long conducting wire as fast as they disappear—as can be done by using an electric machine or other means—the condition in the wire and around it is said to be that of a "steady" or "uniform" electric current. In other words, to maintain a steady current in a wire, its terminals must be kept at a constant difference of potential; and the quantity of positive electricity supplied to one end or of negative supplied to the other in each second of time is called the "intensity" of the current, or the "current strength." The quantity of electricity carried by the current is evidently the product of the current strength and the time. The difference of potential between two points on the wire is called the "electromotive force" (E. M. F.) between those points. It evidently requires energy to maintain a uniform current, because of the energy spent in thermal actions.

Sources of Electric Currents. To maintain a steady electric current, some method must be used which will produce a constant difference of potential. Four may be mentioned: 1. If an ordinary electrostatic machine is used, it will be found to give a current of small intensity, the energy for the current coming from the work done in moving the charges by means of the machine. 2. If two wires of different material, e.g., brass and iron, are joined end to end, forming a single circuit, there will be two junctions of brass with iron; and if these two junctions are kept at different temperatures, there will be (in general) an electric current round the circuit. The energy for this current comes almost entirely from the source of heat at the hot junction, but it may come in part from the fall of temperature of one of the wires. The E. M. F. of the current is, as a rule, extremely small. (See THERMOELECTRICITY.) 3. If two different solid metals, e.g., rods of copper and zinc, dip into a dilute solution of sulphuric acid in water, the two metals will be found to be at a difference of potential. The same is true of any two metals dipping into any liquid—other than a fused metal—which is an electric conductor. Such an arrangement is called a "cell," or "element." The one mentioned has many disadvantages, some of which may be obviated by using two liquids separated by a porous partition. (For a description of different types of cells, see VOLTAIC CELL OR BATTERY.) If a cell, as described above, consisting of a zinc and a copper rod dipping in dilute sulphuric acid is used to produce a current in a wire joining the projecting ends of the two rods, it is observed that the current in the wire is in the direction from copper to zinc; that the zinc rod wastes away, and the loss in mass of the zinc is proportional to the current strength and to the time; that bubbles of hydrogen gas form at the copper rod. It is known from chemical experiments that, when zinc is dissolved in a vessel containing dilute sulphuric acid, hydrogen gas is formed, and the temperature rises, showing that in the reaction energy is given out. In the simple cell just described the zinc dissolves, hydrogen gas is

formed, and the energy liberated is used in producing the electric current. A similar explanation of the supply of energy may be given for all cells, it being noted, however, that in some cases energy is taken from the liquid of the cell itself—apart from chemical action—as is shown by its fall in temperature, and in others energy is given to the cell, as is shown by a rise in temperature. 4. Electric currents may be produced by dynamos (see DYNAMO-ELECTRIC MACHINERY), the principle of which will be examined under *Induced Electric Currents*.

Heating Effect of Currents. Since in a current through a conductor a certain quantity of electricity is passed from high to low potential, it is losing energy, which in turn is gained by the conductor. Thus, if a quantity e has its potential lowered by $V_1 - V_2$, the loss of energy is $e(V_1 - V_2)$; and this is the energy gained by the conductor. If i is the current strength, and t is the time taken for a quantity e to pass, $e = it$. $V_1 - V_2$ is the electromotive force and may be written E . Hence the energy gained by the conductor is Eit . This goes into heating effects and is manifest by a rise in temperature. Illustrations of this heating effect of a current are furnished by the glow, or incandescent, lamp, by the arc lamp, by electric furnaces, etc. One form of lamp (see ELECTRIC LIGHTING) consists of a thin loop of compressed carbon or tungsten inclosed in a glass bulb from which as much air as possible has been exhausted, the two ends of the filament being joined to two fine wires of platinum which enter the exhausted space from without. If by means of these platinum wires an electric current is made to pass through the filament, the latter will be raised to incandescence by the heating effect of the current; but it will not burn, because there is no oxygen in the bulb for it to combine with. The reason for the heating effect being so great in the filament is that it offers a great opposition to the passage of the current, and so a great amount of energy is necessary to force the current through.

The arc lamp consists of two carbon rods so kept by automatic devices that there is a small gap between them. When the lamp is started, the rods are in contact, and a current is forced through from one rod to the other; there is a great rise in temperature at the point of contact, owing to the great resistance to the passage of the current—this makes the air a good conductor: then the poles are drawn a slight distance apart automatically; and owing to the resistance to the current passing from the carbon to the air, the carbon tips are heated white-hot and emit light. See ELECTRIC LIGHTING.

Magnetic Action of a Current. If a long, straight wire carrying a current is held over and parallel to a pivoted magnetic needle, the needle will be deflected to one side or the other, depending upon the direction of the current. The simplest statement of the law of the magnetic action of a current is that a wire carrying a current is surrounded by rings of magnetic lines of force, the connection being such that, if a right-handed screw be imagined placed so as to coincide with the conductor, and if it is turned in the manner indicated by the line of magnetic force, its motion of translation will be in the direction of the current.

If the conductor is bent in the form of a loop, lines of magnetic force will enter the loop on one side and return outside the loop, each line

forming a closed curve. Thus, the face of the loop which the lines enter is like the south pole of a magnet, and the opposite face is like the north pole. In other words, the magnetic action of the loop of wire carrying a current is like a thin sheet of iron filling the area of the loop and so magnetized that all the north poles are on one face and the south poles on the other.

Similarly, if the wire is wound in the form of a helix or spiral spring, the lines of magnetic force will enter at one end of the helix, pass along its length, and, emerging from the opening at the farther end, return outside, forming closed curves. A helix like this when it carries a current has, therefore, the properties of a bar magnet. If a small magnet is placed inside this helix, it will turn and place itself along the line of magnetic force; similarly, if a rod of soft iron or other magnetic substance is wound with an insulated wire helix carrying a current, it will be magnetized. Such magnets are called "electromagnets" and in various forms they play an essential part in call bells, telegraph and telephone instruments, dynamos, motors, etc. The bar of iron is generally so bent that its two ends face each other; sometimes it forms a "horseshoe." One of its ends is then a north magnetic pole, and the other a south pole whenever the electric current is passed through the enveloping helix of wire. Since conductors carrying currents have the magnetic properties of magnets, they have forces of attraction and repulsion on each other and on magnets. It may be shown that all these various cases of force may be embraced in the statement that "motions take place in such a manner that the circuits of conductors inclose the greatest possible number of lines of magnetic force emerging from the north faces of the circuits, or the least number of lines emerging from the south faces." The action of electric motors is based on this principle. See DYNAMO-ELECTRIC MACHINERY.

Many instruments for the detection or measurement of electric currents are based upon their magnetic action. If a magnet is pivoted so as to be free to turn around a vertical axis, and if it is placed in the plane of a loop of wire, it will be deflected if a current is passed through the loop, thus making a "galvanoscope." (See GALVANOMETER.) The delicacy of the instrument may be increased in many ways: making the magnet light and short, winding the wire in several turns instead of a single loop, suspending the magnet by a fine fibre with little if any torsional resistance, making the magnet "astatic."

An astatic magnet is really a combination of two (or more) magnets rigidly fastened to a stiff rod or staff, and so placed that the directive magnetic action of the earth is destroyed as far as possible. This is done by placing the magnets in *opposite* directions, but in the same plane, and making them as nearly as possible of the same strength. In such a compound system in the galvanoscope it is so arranged that one magnet (or set of similar magnets) comes inside the coil of wire, while the other magnet (or set of magnets), turned in the opposite direction, lies outside the coil.

In another type of instrument a flat coil of wire is suspended by a wire which has torsional rigidity between the two poles of a horseshoe magnet, so that the lines of magnetic force enter the coil on one side and return outside the coil on the other.

allel to the faces of the coil. When a current is passed through the coil, it will turn so as to tend to place its faces perpendicular to the line joining the poles, thus forming a straight line of force. The rigidity of the coil prevents the coil from turning far; and the turning moment due to the action of the magnet on the current is balanced by the moment of restitution of the twisted wire. This is the principle of the siphon recorder, of the D'Arsonval galvanometer, etc. Still another form of instrument differs from the one just described in having the magnetic field due to the permanent magnet replaced by one due to an electric current through parallel coils of wire, one on each side of the suspended coil, with their faces at right angles to those of the latter. This instrument is called an "electrodynamometer."

It should be noted that Rowland has shown by direct experiment that an electrostatic charge carried at a high speed has the same effect on a magnet as a current; the direction of the equivalent current depending upon whether a positive or a negative charge is carried.

Electrolysis. Metal wires are not the only conductors for electric currents, although they are the ones most commonly seen. Many liquids are conductors, and all gases may be made to conduct. To pass a current through a liquid or a gas, wires must be used so as to conduct the current in at one point and out at another. The wire by which the current enters is called the "anode"; that by which it leaves, the "cathode." Fused metals conduct like solid metals; but in the case of other liquid conductors (and also some solid ones) there are chemical actions at the anode and cathode: gases are evolved or solid matter is deposited on the metal wires or plates. Such conductors are called "electrolytes," and the process of conduction through them is called "electrolysis." If all electrolytes are examined, it is found that they are the solutions of certain salts or acids in some liquid, such as water, and that there is evidence of the dissociation of the salt or acid by the action of the liquid. Faraday found, by studying the relative quantities of matter separated out from the liquid at the cathode and anode when an electric current was passed through an electrolyte, two laws which bear his name: 1. The mass of matter separated at either cathode or anode in any one electrolyte varies directly as the quantity of electricity carried by the current, i.e., as the product of the current strength and the time. 2. If the same current is passed through several electrolytes in series, the masses of the matter separated out at the different anodes or cathodes vary directly as the "chemical equivalents" of the matter.

The chemical equivalent of any element is its "atomic weight" (see ATOMIC WEIGHTS) divided by its "valence." For example, the chemical equivalents of a few different substances are given in the following table:

Hydrogen	1
Oxygen	7.93
Copper	31.59
Zinc	32.44
Silver	107.66

Assuming the truth of Faraday's first law, a convenient method is offered for comparing the current strength of different currents, viz., pass the currents in turn through the same electrolyte and weigh the quantities liberated in the same time. The current strengths are in the

ratio of these masses. This is the principle of the so-called silver or copper "voltameters."

Faraday pictured the phenomena of electrolysis as being due to the passage in the electrolyte of two streams of particles—one set charged positively going towards the cathode, the other charged negatively going towards the anode. These carriers of charges he called "ions"; and he thought of them as giving up their charges to the cathode and anode, and then being liberated from the liquid as gases or solid deposits, or as then taking part in chemical reactions and thus liberating other substances. It is easily seen that, if Faraday's laws are exact, all ions of the same substance, e.g., hydrogen, must carry the same charge in whatever electrolyte they appear, and, further, that the charge on any ion is proportional to its valence. (Thus, if the charge on a hydrogen ion is e , that on a copper ion must be $2e$, because the valence of copper is twice that of hydrogen.)*

The modern theory of electrolysis is one of the most important branches of physical chemistry. Only its essential ideas need be mentioned here. As it is known by evidence from many sides that an electrolyte consists of a pure liquid in which a salt or acid is dissolved and dissociated into parts, it is natural to identify the ions with these fragments of the molecules of the salt or acid. The theory at present accepted is that by the act of solution in a liquid some substances are dissociated, at least in part, e.g., sulphuric acid in water; i.e., some of the molecules of the dissolved substances break up into smaller parts. It is not thought that the parts of a molecule once dissociated remain separated, but that there is a state of dissociation and recombination going on as the molecules and their parts move about through liquid, and at any instant a definite proportion of molecules are dissociated. It is natural to think that, if a molecule is broken into parts, which are then separated, they will be electrically charged, one portion positively, the other negatively. (The charges on any part would then vary as its valence.) If now a difference of potential is produced in the liquid by inserting the anode and cathode, all the positively charged parts will, during their intervals of dissociation, be urged towards the cathode, while those negatively charged will move towards the anode. (It is possible that these dissociated parts do not move freely by themselves, but drag with them definite masses of the solvent.) On this theory, which accounts perfectly for the observed phenomena of electrolysis, the ions are charged fragments of molecules. When they get to the anode or cathode, they give up their charges and combine with other ions, thus forming molecules which are liberated. See DISSOCIATION; ELECTROCHEMISTRY, GENERAL.

Discharge through Gases. There is reason for believing that a pure gas would be a perfect insulator; but all gases can be made conductors in many ways, in all of which there is evidence that the molecules of the gas have been broken

*It is evident that the processes of silver or of copper plating are simply cases of electrolysis. (See ELECTROCHEMISTRY, INDUSTRIAL.) In the former a solution is made of a silver salt, a piece of silver is used for the anode, the body to be "plated" is made the cathode and, as the current is passed through, silver is deposited on the latter and dissolves off the former. Electrolysis is used extensively, too, for the preparation of pure metals, e.g. copper, aluminium, etc. See METALLURGY.

into parts, i.e., "ionized"; although the ions in a gas are by no means the same as in a liquid electrolyte. Some of the methods for ionizing a gas are the following: (1) application of high temperature, e.g., the gases rising from a Bunsen flame are conductors; (2) passage of a spark in the neighborhood; (3) exposure to Röntgen rays or to rays from a radioactive substance, such as uranium (q.v.); (4) exposure to "cathode rays" (see below); (5) exposure to "ultra-violet light." (See LIGHT.) One most important fact which seems to be established is that the negative ions of all gases, however these ions are produced, are identical. It can be proved also that the negative ions have less mass than the positive ones. For a full discussion of the recent work on this subject, reference must be made to J. J. Thomson's *The Discharge of Electricity through Gases* (London, 1902) and to publications by Professor Thomson and his students in the *Philosophical Transactions* (ib., current). See IONIZATION.

One of the most interesting illustrations of the passage of electricity through a gas is afforded when the gas is inclosed at low pressure in a glass tube into which enter two metal wires serving as anode and cathode. When the gas is at a pressure of a few centimeters of mercury, and a discharge of electricity through the tube is produced by an induction coil or by a number of cells, the gas near the anode is apparently arranged in colored striations across the tube, while near the cathode there is a dark space and over the cathode itself there is a velvety glow. (The light emitted from the tube is characteristic of the gas inside. See SPECTROSCOPY.) As the tube is exhausted further, so that the pressure of the gas decreases, the dark space round the cathode extends through the tube. Finally, if the exhaustion is continued, the character of the phenomenon is changed by the gradual appearance of the cathode rays. These are streams of minute particles of matter negatively charged, which leave the cathode perpendicularly and proceed in straight lines through the gas in the tube. These cathode rays are themselves invisible, but their various effects where they pass where they strike the wall of the tube at this last place they produce thermal effects also. They produce mechanical motion if they strike any small movable object in the tube. Their path can be deflected by a magnet, proving that they are negatively charged particles moving with great speed—about 25,000 miles per second. If at the end of the tube on which the cathode rays strike there is a small opening covered with a thin sheet of aluminium, similar rays are observed outside the tube. These were first observed by Lenard and are called "Lenard rays." Cathode rays affect photographic plates; and, further, wherever they strike any solid obstacles, disturbances in the ether are produced, which in turn cause other radiation. These were discovered by Röntgen and are called "Röntgen rays," or "X-rays" (q.v.). The best discussion of cathode rays is given in *Les rayons cathodiques*, by Villard (Paris, 1900).

Laws of Steady Electric Currents. Advantage is taken of the action of an electric current on a magnet to define a "unit current." A unit pole in magnetism is defined as such a pole that, if two of them are at the distance of one centimeter apart in a vacuum, the force between them

will be one dyne. A unit current is defined as being one of such intensity that, if it is passing through a wire bent into the form of a circle of radius one centimeter, the force due to it on a unit pole at the centre of the circle is 2π , where $\pi = 3.14159$. This unit is called the "C. G. S. unit"; and it has been shown by experiment that its ratio to the "C. G. S. electrostatic unit" is 3×10^{10} . A current of intensity 2 around the same circular circuit would produce the force 4π on a unit pole at the centre; and experiments show that if a current of intensity i is passed around a circular circuit of radius r centimeters, the force on a unit pole at the centre is

$$\frac{2\pi i}{r}.$$

If there are n turns of wire making up a flat coil of radius r , the force on a unit magnetic pole placed at the centre is

$$\frac{2\pi ni}{r}.$$

The "dimensions" of a magnetic pole are $M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-\frac{1}{2}}\mu^{-\frac{1}{2}}$ (see MAGNETISM); and since the force on a pole of strength m due to an electric current as just described is $\frac{m2\pi i}{r}$, the dimensions of this fraction must be those of a force, i.e., MLT^{-2} . Since the dimensions of m are given and r is a length, i , the current strength, has the dimensions $M^{\frac{1}{2}}L^{\frac{3}{2}}T^{-\frac{1}{2}}\mu^{-\frac{1}{2}}$. Therefore, on the C. G. S. electromagnetic system, an electric quantity has the dimensions $M^{\frac{1}{2}}L^{\frac{1}{2}}\mu^{-\frac{1}{2}}$; μ in these expressions represents the dimensions of magnetic permeability, or inductivity, as it is called.

If a small magnetic needle is pivoted at the centre of a coil with its axis in the plane of the coil, there will be a couple (q.v.) acting on the needle tending to make it turn at right angles to the coil. This couple may be balanced against a couple due to the earth's field of magnetic force; and in this manner the current strength i can be measured in terms of the earth's field of force. Such an instrument is called a "galvanometer," because it measures a steady electric current. By means of it Faraday's laws of electrolysis may be verified. The number of grams of any substance liberated each second when a unit current passes through an electrolyte is called the "electrochemical equivalent" of that substance. The values of this quantity for some elements are given in the following table:

Hydrogen	0.000104
Oxygen	0.000829
Copper	0.003290
Zinc	0.003385
Silver	0.011180

The number of tubes of magnetic induction (see MAGNETISM) which pass through any coil of wire when it carries a unit electric current is called its "coefficient of self-induction"; and the number of tubes which pass through a second coil of wire owing to this unit current in the first coil is called the "coefficient of mutual induction" of the two coils. It may be proved that this same number would pass through the first coil if there were a unit current in the second. These coefficients of self and mutual induction—sometimes called simply "the induction"—are mathematical functions of the size

and shape of the coils, of their relative positions, and of the surrounding medium, but are independent of the currents. If L_1 is the coefficient of self-induction of one coil, and M that of mutual induction between it and a second coil, and if currents of intensities i_1 and i_2 respectively are flowing in the two coils, the number of tubes of induction through the first coil is $Li_1 + Mi_2$.

If the electromotive force applied to the terminals of a metal wire is varied, and the corresponding current measured, it is observed that one bears a constant relation to the other. If i is the current strength and E the electromotive force, $E = Ri$, where R is a constant for the given wire, and is found to vary directly as the length of the wire and inversely as its cross section, and to be different for different metals or for the same metal at different temperatures. R is called the "electrical resistance" of the given wire at whose terminals the E. M. F. E is applied. This law connecting E , R , and i is called "Ohm's law."

The heating effect in the conductor has been shown to be Eit ; and so this may be written i^2Rt , showing that the effect is the same for a plus as for a minus current, i.e., it is independent of the direction of the current.

Measurement of Electrical Quantities. As already explained, the intensity of an electric current may be measured in terms of the earth's magnetic force by a galvanometer, and the value of this force may be determined by suitable measurements. (See MAGNETISM.) Thus the numerical value of any current on the C. G. S. electromagnetic system may be obtained. (There are other and better methods, depending upon the attraction of two parallel coils of wire carrying currents.) The intensities of two currents may be compared by making them pass through a voltmeter (q.v.) and then applying Faraday's first law of electrolysis. To measure the electrical resistance of a conductor the simplest method—at least theoretically—is to measure by means of a calorimetric experiment the heating effect in it produced by passing through it a current whose intensity is measured. The heating effect is i^2Rt ; and, as both i and t are easily obtained, R can be calculated. This will be its numerical value on the C. G. S. electromagnetic system. To compare the electrical resistances of different conductors, the simplest and most accurate method is the use of "Wheatstone's bridge" (q.v.). If the resistance of a given conductor is known, and if the current produced through it by any E. M. F. can be measured, the numerical value of this E. M. F. is given by Ohm's law. Methods for the comparison of different electromotive forces are described in all textbooks on physics and electricity. Owing to the inconvenient magnitude of the units of resistance and of electromotive force on the C. G. S. electromagnetic system, other units have been adopted for practical use. See ELECTRICAL UNITS.

The "ampere" (q.v.), or practical unit of current, is one-tenth the C. G. S. electromagnetic unit; the "ohm," or practical unit of resistance, is substantially 10^9 C. G. S. electromagnetic units; the "volt," or practical unit of electromotive force, is substantially 10^9 C. G. S. electromagnetic units.

Induced Electric Currents. If the magnetic field inclosed by any conductor, e.g., a wire bent into a closed circle, is varied in any way, there

will be produced in the conductor an electric current, which continues only while the change goes on. This is called an "induced current," and it is said to be due to an induced E. M. F. If there was a current in the conductor originally, it will be either increased or decreased, depending upon the direction of the induced current. This last is in such a direction that by its action it will oppose that change in the field which produces it. Thus, if the change is due to the approach of a magnet having its north pole foremost, the induced current will be such as to cause the repulsion of the north pole; while, if the change is due to the removal of the north pole of the magnet, the induced current will be in the opposite direction. The change in the magnetic field may be due, also, to the approach or removal of electric currents, to the change in the intensity of neighboring currents, or to changes in the original current in the conductor itself. Special cases of this last kind are afforded when a conductor carrying a current is broken, and also when the broken parts are reunited, thus again starting the current. In the former case the magnetic field starts at once to decrease; and owing to this there will be an induced current tending to neutralize the change in the magnetic field, i.e., in the same direction as the original current; this is shown by the spark which passes between the ends of the conductor where the circuit is broken. (This "extra current on breaking" is used often to produce a shock in the muscles of the arms or body; for, by increasing the magnetic field of the original current by winding the wire in a helix, a powerful shock may be felt.) When the circuit is again made, if the current regained its original value at once, there would be a sudden increase in the magnetic field; as the field increases, however, there are induced currents tending to oppose the change, and hence the current regains its former value at a rate depending on the self-induction and the electrical resistance of the conductor—a very short time, however, in general is required. In all cases the induced E. M. F. (and therefore the intensity of the induced current) varies directly as the change in the tubes of magnetic induction, and inversely as the time taken in which to accomplish this change. The induced E. M. F. equals the change in the number of tubes of induction in one second. In fact, the simplest way of defining a unit of self or mutual induction—or "unit induction"—is to say that it is the induction in a circuit when the induced E. M. F. in it has the value one, while the inducing current varies at the rate of one unit per second. For, if M is the coefficient of mutual induction between two coils, and if a current i passes through one, there are Mi tubes through the other; therefore, if the current i varies at the rate of one per second, Mi will vary at the rate of M per second; but the induced E. M. F. equals the rate of variation of Mi , i.e., equals M ; so, if the induced E. M. F. is unity, M must equal one. The energy required to produce the current comes from whatever agency changes the magnetic field, except when a current is made or broken, i.e., except cases involving self-induction. On breaking a circuit which carries a current, the cell or other source of E. M. F. ceases to furnish energy; and that required for the "extra current" comes from the surrounding medium; so this current continues only so long as this sup-

ply lasts. This energy of the medium is associated with the magnetic field around the conductor due to the current. Similarly, when a current is "made" by joining the two ends of the broken conductor, the cell or source of E. M. F. begins to furnish energy; and this is spent in two ways at first, in producing the magnetic field and in overcoming the resistance of the conductor. When the current rises to its full value, as given by Ohm's law, the magnetic field reaches its final value, and all the energy now goes to overcoming the resistance (i^2Rt). This energy of a magnetic field—around either a current or a permanent magnet—is undoubtedly kinetic; the ether and the portions of matter, if they are magnetic, are in motion. Clerk-Maxwell has shown how magnetic actions can be explained if a line of magnetic force is a linear vortex, the ether and the very small portions of matter spinning around this line as an axis, and if these different vortices are made to depend on one another by means of some kind of mechanism connecting them.

The applications of induced currents are almost too numerous to mention: earth inductors to measure the direction and intensity of the earth's magnetic field; induction coils to produce sparks, etc.; transformers as used commercially to reduce or increase the E. M. F. of currents; all forms of dynamos; the telephone; all apparatus that depends upon the use of alternating currents, etc.

Alternating Currents and Electrical Waves along Conductors. If the E. M. F. impressed upon a conducting circuit is not constant, the current will vary and there will be complications owing to the induced currents. In particular, if the E. M. F. is periodic in the same way that the motion of a pendulum is periodic, i.e., if it rises to a maximum, decreases to zero, becomes negative, reaches a maximum negative value, increases to zero, then to its positive maximum, etc., according to the formula $E = E^0 \cos pt$, the E. M. F. and the current are the simplest cases of "alternating" electromotive forces and currents. E^0 is the maximum E. M. F., and the number of times the E. M. F. makes a complete period in one second is $p/2\pi$ (where $\pi = 3.14159$). If the conductor to which this alternating E. M. F. is applied is not too long, the intensity of the current in all parts of it will be the same at any one time; but if the conductor is many miles long—like an ocean cable, or a telephone or telegraph line over long distances—the E. M. F. and the intensity of the current will vary from point to point in such a way that there is a wave of E. M. F. and of current in the conductor. (These facts are perfectly analogous to the phenomena observed on shaking sidewise periodically one end of a short rope or of a long stretched rope.) The rate of transmission of the electrical waves along the conductor depends upon the properties of the conductor and the surrounding medium; and it can be proved that the rate at which the amplitude of the wave—i.e., the maximum value of the current at any one point—decreases owing to absorption of the energy of the waves varies with the wave length. Long waves, i.e., those for which p is small, die down more slowly than short waves, for which p is large. It is owing to this fact that long waves travel farther than short ones; and therefore on ocean cables very long electrical waves are used. A discovery made in 1900 by Professor Pupin of Co-

lumbia University has shown a method by which a special kind of conductor—one in which coils of wire are introduced at regular distances—will convey all waves (within certain limits) to the same distance and will convey them much farther than will an ordinary wire or cable.

Hall Effect. One of the most important effects of a magnetic field on an electric current is observed when a thin sheet of metal, e.g., gold foil, is traversed by an electric current and is held between the poles of an electromagnet. When there is no magnetic field, the current flows through the sheet in a definite manner; and it is possible to find pairs of points on opposite edges of the sheet which have the same potential: this can be done by joining one terminal of a galvanoscope to one edge and then joining the other terminal to such a point on the other edge that there is no current through the instrument. If now the electromagnet is made to produce a field of magnetic force perpendicular to the sheet, there will be a steady current through the galvanoscope. If the magnetic field is reversed, so is this current. This effect was first observed by E. H. Hall in 1880 and is called the Hall effect. The action is exactly as if, owing to the magnetic field, the line joining the two points on the two edges, which were at the same potential, were rotated slightly around an axis parallel to the lines of magnetic force. This action varies greatly for different metals, both in direction and amount, and is proportional to the strength of the magnetic field and to the current strength in the sheet.

Faraday Effect. Faraday observed in 1845 that, if a beam of plane polarized light is passed through a hollow iron rod forming the core of an electromagnet, the plane of polarization (see LIGHT) is rotated when the current is passed around the helix forming the magnet. The rotation is in the direction of the current in the helix; i.e., it obeys the "right-handed screw law." The amount of the rotation varies greatly with the material which occupies all or part of the hollow iron core and is proportional to the intensity of the magnetic current.

Both the Hall and Faraday effects are evidences of the rotatory action around a magnetic field of force.

Bibliography. While the bibliography of electricity is extensive, the subject will be found fully treated in the larger textbooks of physics. Of the reference books dealing exclusively with electricity and magnetism the following are recommended, and for the convenience of the reader are grouped in three classes: MATHEMATICAL AND ADVANCED TREATISES: Clerk-Maxwell, *Electricity and Magnetism* (2 vols., London, 1881); Webster, *The Theory of Electricity and Magnetism* (New York, 1907); Tait and Betti, *Recent Researches in Electricity and Magnetism* (London, 1903). ELEMENTARY TEXTBOOKS: Thomson, *Elements of the Mathematical Theory of Electricity and Magnetism* (London, 1895); Gerard, *Electricity and Magnetism* (New York, 1897). ELEMENTARY AND DESCRIPTIVE WORKS: Perkins, *Outlines of Electricity and Magnetism* (New York, 1896); S. P. Thompson, *Elementary Lessons in Electricity and Magnetism* (ib., 1881, 1902); Gordon, *Physical Treatise on Electricity and Magnetism* (2 vols., London, 1883); Glasbrook, *Electricity and Magnetism* (Cambridge, Eng., 1903); Starling, *Electricity and Magnetism* (London, 1912); Poynting and Thomson, *Electricity* (ib., 1914).

ELECTRICITY, ANIMAL. The property in animal tissues, as nerves and muscles, to produce electrical reactions. It is exhibited especially in various rays, eels, etc. See **ELECTRIC FISH**.

ELECTRICITY, ATMOSPHERIC. See **ATMOSPHERIC ELECTRICITY**.

ELECTRICITY, MEDICAL USES OF. Three forms of electricity are used in medicine: static, galvanic, and faradic. Static electricity is obtained from a frictional machine in which glass plates are rapidly revolved against chamois rubbers or horsehair brushes. The electricity is produced in a succession of sparks, which may be received in a Leyden jar or in the body of a patient insulated by being placed on a glass-footed chair. Static electricity has but little quantity, but an enormous electromotive force; the current has high potential and high frequency, but is devoid of appreciable electrolytic effects. Its use in medical practice is to modify and regulate functional processes, including secretion, excretion, sleep, circulation, and nutrition; in subacute or chronic inflammatory conditions, neuroses, paralyses, muscular contractions, skin affections, cancer, tuberculosis, etc.

High-frequency currents are now extensively used for relieving pain, increasing metabolic changes either locally or generally, increasing the blood pressure, and increasing circulation. An alternating current is derived primarily from a static machine or induction coil and is produced by the continuous charging and discharging of a pair of Leyden jars or condensers. The charge is received by the inner coating of the jars, and the current allowed to spark between metallic balls connected with this inner coating. The oscillations thus produced are estimated at a million per second. The patient does not receive this current directly, but it is first passed from the outer coating of the condensers to an Oudin resonator or Tesla coil, which increases the voltage from hundreds of thousands to over a million volts. The patient experiences only a sensation of warmth when glass vacuum electrodes are employed in the application; with metal electrodes a spark results, which is often utilized for destroying abnormal tissue.

Galvanic electricity is obtained from a galvanic battery, composed of several cells connected in the usual way, the terminal wires being inserted into metal binding posts, to which electrodes are fastened. The elements used are zinc and carbon immersed in a solution of bichromate of potash containing sulphuric acid and also a salt of mercury. A current controller, or switch, is so arranged that one, two, three, or more cells may be used at a time, according to the strength of current desired. The electrodes, or terminals, which are applied to the body, are composed of metal disks, covered with sponge and insulated so as to be grasped by the wooden handles by the physician without drawing off the current. The sponges are wet before applying. Galvanism causes a contraction of the muscle against which the electrode is applied, on application and again on withdrawal. During the interval of application there is a sensation of heat (also of pain if the amperage be great) and of tingling. A sensation of light, a metallic taste, or a buzzing sound is experienced when the current is passed through the retina, the tongue, or the ear respectively. Galvanism is applicable in treating

very many conditions and diseases of the nervous system as well as of the greatest use in diagnosis of these diseases.

Faradism is obtained from a faradic battery. An important part of this apparatus is a small induction coil consisting of a core of short, straight, soft iron wires of large diameter, around which are coiled many feet of wire. Through the wire is run an electric current which when interrupted causes an induced current to flow in a second and surrounding coil and turns the iron core into an electromagnet. Passing through the coil to the spring support of the vibrator, the current goes thence to the platinum point on the interrupter and thence back to the cell, completing the circuit. But as the current, in passing through the coil, makes the iron core an electromagnet, it furnishes the energy that attracts the hammer on the spring support, which, drawn to the magnet, breaks the circuit in leaving the platinum point of the interrupter; the current then ceases, the iron core loses its magnetism, the spring ceases to be attracted to the iron core, and its tension causes it to return to its former position, in which it touches the platinum point of the interrupter again, and again the circuit is closed. Thus, the circuit is made and broken with extreme rapidity and frequency. The secondary coil is insulated from the primary coil, and its terminals are connected with the electrodes. The rapid making and breaking of the current in the primary produces an induced current in the secondary which can be regulated at will by the operator. This induced current is applied to the human body by means of electrodes, as in the galvanic battery. The effects of faradism are wholly electrotonic. It is useful in mild cases of spinal and peripheral paralysis. Changes of circulation or of molecular state may be excited in central organs by reflex irritation produced by faradism. General faradism is beneficial in gout and rheumatism, myalgia (muscular rheumatism), in widespread eczema, in constipation due to indigestion, in hypochondria, hysteria, and neurasthenia. Local faradism is beneficial in but few cases which are not ameliorated in larger measure by galvanism. Faradism is useful in testing conditions of muscles; but here, too, galvanism is of greater value. Special electrodes of various shapes are used in applying the current to different parts of the body. A flat oval electrode, about 6 by 4 inches, is useful in applications to the abdomen or spine; a small pointed electrode, for singling out one muscle of a small area or testing a nerve; a small oval bean-shaped electrode, fastened to a rubber-covered wire, for swallowing in order to electrify the interior of the stomach; an electrode shaped like a *hook*, with all but a half-inch of the *hook* for intrauterine use; a wire brush, for special use with the faradic current, etc. An interrupting electrode is so made that with the thumb or the hand that manipulates the electrode the circuit may be closed and opened at will for testing accurately. A special electrode is arranged for the insertion in its extremity of bibulous paper saturated with a drug in solution, which is carried into the skin, when a current is passed, using this as the cathode. This is called the cataphoric electrode. A galvanic battery is furnished with a device by which the current may be run in different directions by moving a switch, thus altering the polarity of an elec-

trode without moving it. This is especially useful in testing for degeneration in a muscle. Normally the cathodal closure contraction of a muscle is greater than the anodal closure contraction. If degeneration has occurred in a nerve supplied to a muscle, the anodal and cathodal closure contractions may be equal, or the anodal may be greater than the cathodal. Faradic contractility is less in a muscle supplied by a nerve than in one in a normal means of the cataphoric electrode a medicine like iodide of potassium may be used locally in definite quantity, as in a glandular enlargement; or cocaine may be applied over the painful spot in a neuralgia or neuritis, or may be applied to the gum of a sensitive tooth before filling or extraction.

Besides the use of electrization in several diseases, as stated under their own titles, in paragraphs on treatment, galvanization is of immense value in paralyzing muscles, securing their rest, preventing their atrophy until relief of the central condition has been accomplished or regeneration of nerves been secured. In surgery the electrolytic action of the galvanic current is employed in destroying tumors; destroying hypertrophied tissue, as in the nasal cavity; removing naevi and birthmarks, or superfluous hair, etc. The galvanic current is also utilized in heating a cautery for searing a surface or area, to secure a cicatrix; for causing counterirritation, etc., its utility over the ordinary or Paquelin's cautery being largely due to the fact that it can be placed in position when cold, and instantly heated to the required degree by passing through it a current of known amperage. J. Langner, *Electro-therapeutical Practice* (St. Louis, 1912); Jones, *Medical Electricity* (6th ed., Philadelphia, 1913). See DENTISTRY.

ELECTRIC-LIGHT BUG. See FISKEILLER.

ELECTRIC LIGHTING. Illumination produced by the conversion of electrical energy into light, usually through the agency of either arc or incandescent lamps. The electric current is generated by dynamos driven by steam, gas, or water power, and may be either alternating or direct current and of either high or low potential. In its broader sense the term "electric lighting" includes the operation of agencies for the production and distribution of electric current as well as electric illuminants. The arc light is produced when an electric current flows through a bridge of vapor or arc between two conductors, called electrodes. (See **ELECTRIC ARC**.) The incandescent lamp has a filament of carbon or of refractory metal mounted in an exhausted glass bulb. The resistance of this filament to the flow of current causes a transformation of electric energy into heat of such an intensity that the filament glows with brilliant incandescence.

Early History. The basic discovery of the electric arc is credited due to Sir Humphry Davy, who in 1800 discovered the electric arc and produced the incandescence of a fine platinum wire in connection with his famous experiments with a 2000-cell battery. The developments of the following 50 years were

solely of a scientific nature, as the dynamo machine had not been invented. In 1862 an arc lamp was installed in a lighthouse at Dungeness and supplied with current from a cumbersome magneto-electric machine. This light was in use for many years and is generally credited with being the first electric lamp in regular service. Gramme's dynamo of 1870 opened a new era in electrical development, yet there were but two exhibits of electric lighting at the Centennial Exposition of 1876. In 1878 Paul Jablochhoff's "electric candle" created a great sensation at its initial exhibition in Paris. He arranged two carbons vertically, side by side, with baked kaolin between, and so dispensed with a feeding mechanism, which previously had been the source of great difficulty in arc-lamp construction. The arrangement proved unsuited to extensive use. In the same year Charles F. Brush, of Cleveland, devised a complete system of arc lighting, including a special form of dynamo and a type of self-regulating arc lamp for series operation. The Thomson-Houston system and a number of others followed very shortly. The Brush system with minor modifications is still in extensive use.

The Edison incandescent electric lamp was first exhibited in 1879 at Edison's laboratory in Menlo Park, N. J. Edison's invention comprised a complete system of generation and distribution at constant potential, with the current subdivided between the several circuits and lamps, as well as the first practicable incandescent lamp. The basic principles employed by Edison had long been known, but he was the first to surmount the enormous experimental difficulties in the development of a practicable lamp and the agencies for its energy supply. The Pearl Street Edison Station in New York was put in service in 1882 and was the forerunner of the great central stations of to-day. Of the previous attempts at incandescent lamps the most promising was described in a British patent issued in 1845 to an American named Starr, whose early death at the age of 25 rendered his work abortive. Until 1885 little use was made of alternating current for electric lighting. The invention of the transformer in that year made possible the transmission of electric currents at higher potentials than could be applied directly to the lamps and so opened the field of electric lighting in regions remote from generating stations. Later developments have multiplied the varieties of incandescent and arc lamps and have wonderfully increased the flexibility and range of electrical generation and transmission.

Central Station is a term used to designate a plant at which electric current is generated to supply many consumers, while an *isolated plant* supplies the wants of a single building or a contiguous group of buildings. The developments of high-voltage power transmission have made it possible to supply electric service at great distances. A notable example is found in the group of power stations at Niagara Falls, from which transmission lines radiate to many cities for the supply of lighting and power services. In some instances these cities are more than 200 miles distant. (See **POWER TRANSMISSION**.) The central stations in large American cities are for the most part steam-generating plants, and many of them are of enormous capacity. The largest electric-lighting system in the world is that of the Commonwealth Edi-

son Company of Chicago. This system is supplied by a group of four stations having an aggregate capacity of 320,000 kilowatts, or 430,000 horse power. The largest single generating unit in the world, a steam turbogenerator of 35,000 kilowatts, is employed in the Fisk Street Station of this company. The greater part of the output of these stations is distributed in underground cables at 9000, 12,000, or 20,000 volts to 41 substations, where it is converted to a form adapted to local needs.

Distributing Systems are for the most part of copper wire, but aluminium has an extensive use, especially in long-distance transmission. The conductivity of copper is about double that of aluminium, but, owing to its lower density, an aluminium conductor weighs only 61 per cent as much as one of copper having the same length and resistance. Aluminium is at a disadvantage for use in cables, owing to the greater space which it occupies and the larger surface to be insulated as compared with copper. In the central districts of the larger cities overhead wires have now been quite generally replaced by underground cable systems in conduits. The underground system is safer and less liable to accidental injury, but its initial installation is much more costly than a system of overhead wires. In many districts the latter have been banished by law, to increase public safety and convenience. (See CABLE, ELECTRIC; TRANSMISSION OF POWER BY ELECTRICITY; SUBWAYS.) Distributing systems divide broadly into two basic types, viz., *series*, constant-current, and *parallel*, constant-potential, which in practice are often complicated by various combinations.

In the simple series system the current passes from the dynamo through each lamp successively and returns to the dynamo without subdivision at any point. The current is usually maintained constant by automatic regulating devices, but the voltage or potential is varied according to the number of lamps and the resistance of the circuit. An extensive series circuit may supply 150 arc lamps with a current of from 4 to 10 amperes and require a voltage as high as 12,000. Parallel systems employ constant potential, but the current is subdivided among all the lamps and other receiving devices and varies according to the number in use. In the parallel system each lamp or group of lamps is controlled separately, whereas series circuits are usually thrown on or off as a whole. The usual supply voltage of parallel systems is between 100 and 125 volts. The parallel system is extremely flexible and safe, but has the disadvantage of requiring a large aggregate weight of conductors. The series system is well adapted to systems where all the lamps are controlled simultaneously and where high voltage conductors can be safely installed. Its greatest use is for street lighting. Suitable arc and incandescent lamps of all types are available for both systems.

The parallel system is in practically universal use for general power and lighting supply. Current may be furnished by either direct- or alternating-current generators, though the former are now used chiefly in small isolated plants. Most of the direct-current supply in large cities is confined to the central districts and is obtained from substations where alternating current is received at high potential and converted by dynamo machines to direct cur-

rent. Direct current is commonly distributed by a three-wire system, which is equivalent to two two-wire circuits with a common conductor. When the two component circuits carry equal currents, little or none flows in the common wire, and the voltage drop is due only to the resistance of the outer wires. All three wires may therefore be made much smaller than in two separate circuits, and a saving of from 25 to 70 per cent is possible, depending on the degree to which balanced loads can be guaranteed. Alternating current is usually generated at a voltage of 2300 or higher and is delivered over relatively small transmission wires to transformers placed at important load centres, where it is stepped down in voltage and delivered to the lamps by a secondary system of conductors.

Arc Lamps. The essential elements of an arc lamp are a pair of electrodes, the regulating devices needed to establish an arc and feed the electrodes as they are consumed, and the necessary connections to an external circuit. Arc lamps are generally designated by the type of electrodes employed, as carbon, flame carbon, metallic oxide, and mercury arcs. Arcs are also divided into series and parallel types according to the system of distribution to which they are adapted. Distinction is also made between open arcs and inclosed arcs, according as the arc is

INCLOSED ARC LIGHT.
A. Direct current. B. Alternating current.

operated with free or with restricted access of air.

The ordinary carbon arc has long cylindrical electrodes prepared from petroleum coke, gas coke, or lampblack. The raw materials are successively crushed, roasted, powdered, and bolted.

then are mixed with hot pitch; this compound is allowed to cool, and is then powdered, reheated, and formed in molds or forced through dies into cylindrical form, and is finally baked. The better grade of carbons are usually forced.

INCLOSED FLAME ARC LAMP.

In some cases a cored carbon is produced by filling an axial hole in the carbon with a mixture of powdered carbon and salt. This mixture volatilizes more readily than the basic carbon and so improves the steadiness of the arc.

Carbons for flame arcs are strongly impregnated with mineral salts. Calcium salts are employed when an orange light is desired and barium salts for white. The ordinary carbon arc owes its light chiefly to the incandescence of the ends of the electrodes, and its arc stream is of a feeble bluish color. The mineral salts vaporized into the flame arc impart to it a brilliant luminescence and greatly increase its luminous efficiency. Both types of carbon arc can be operated by either direct or alternating current, while other types of arc operate with direct current only.

The metallic oxide or magnetite arc has a positive electrode of copper, which remains inert and is not consumed to maintain the arc. The active or negative element is a mixture of oxides of iron, titanium, and chromium powdered fine and packed in an iron tube. This mixture produces an arc flame of very white color and excellent efficiency. The mercury arc, commonly called the mercury vapor lamp, can be produced only in highly exhausted glass or quartz tubes. Its greenish color is due to the peculiar spectrum of mercury vapor, which is strongly deficient in red rays. The low-pressure arc in a long glass tube produces light of moderate brilliancy at low temperature. The high-pressure arc develops a temperature sufficient to soften glass and requires a quartz tube. The high-pressure arc produces some red rays and is of fairly high brilliancy.

Regulating devices are required to feed the electrodes of arc lamps so that the arc is maintained constant in length and candle power. Ordinary carbon arcs are provided with stationary lower electrodes. The upper carbon is held

by a clutch and feeds downward by gravity whenever this clutch is released. The clutch is controlled either by a train of wheelwork, an electrical or mechanical motor, or by solenoids. The solenoid mechanism is now almost universally used. The clutch is often a simple collar, which is released when the arc burns to a certain length and resistance. The slip of the carbon is checked by the lifting action of the clutch when the proper arc length has been restored. The arrangement of the electrodes in flame arcs follows two different types. In the Bremer type the carbons are long and slender. They converge downward, and the arc is formed between their tips, giving a powerful downward light distribution. The carbons are fed down inclined slides by gravity, with the rate of descent controlled by a clutch regulated by solenoids. Arcs of this type produce copious fumes and must be open for positive ventilation. The life of the carbons is short, and the expense of trimming is large. The Blondel type of flame arc uses short and thick vertical carbons, both of which are fed as consumed to maintain a constant arc level and length. The usual feed device is a chain run from the top of the upper carbon over a pulley and attached to the bottom of the lower carbon. As the arc lengthens by the burning of the electrodes, an electrically controlled clutch is released, the upper carbon descends, and the lower rises by equal amounts until proper arc length is restored. The more

GENERAL ELECTRIC MAGNETITE
ARC LAMP.

DIRECT-CURRENT-SERIES
LUMINOUS ARC LAMP.

modern flame arcs of this type are tightly inclosed and have a condensing chamber in the housing above the arc into which the fumes are swept by air circulation and in which their fumes are allowed to settle out. The life of such lamps per trim is from 100 to 125 hours, or

about the same as the best inclosed carbon arcs, while the efficiency of the flame arc, viz., 0.25 to 0.6 watt per candle, is from four to five times as good as that of the carbon arc.

The regulating mechanism of the magnetite arc allows the arc to increase in length and resistance up to a certain point, then forcibly brings the electrodes together and forms the arc anew. This method of feeding is necessary for the removal of the slag, which tends to incrust the negative electrode. The tube of a mercury arc is always somewhat inclined and is provided with a condensing chamber at its upper end. The mercury is restored to the lower electrode after condensation by gravity.

Arc lamps are essentially high-candle-power illuminants and are relatively less steady in their operation than incandescent lamps, due to the intermittent action of the feeding devices. Their greatest field of utility is in the illumination of streets and large spaces where large units are advantageous and steadiness of light not imperative. While carbon arcs are less efficient than the best incandescent lamps, many are still in use in interiors for the sake of the whiteness of their light or the rugged nature of their construction. The performance in life and efficiency of the arc lamps in commonest use are given in round numbers in the accompanying table. The candle power is a misleading unit of light output, as it may refer to the intensity of light in a single direction or in the mean of many directions. The following data are based on the average candle power in the lower hemisphere of light distribution, which is perhaps the most significant single measure of the utility of a lamp for street lighting.

Type of Lamp	Watts per candle	Life per trim
Carbon arc, inclosed....	0.7-2.0	100-150 hours.
Flame arc, open type...	0.3-0.5	10-17 "
Flame arc, inclosed....	0.3-0.5	100-150 "
Magnetic arc, open....	0.4-0.6	125-200 "
Mercury arc, glass.....	0.5-0.65	1000-2000 "
Mercury arc, quartz...	0.3-0.4	2000 hours and up.

Incandescent Lamps are usually designated as carbon, metallized carbon, tantalum, or tungsten lamps, according to the nature of their filaments. The material of the filament must of necessity be electrically conducting, extremely refractory, mechanically strong, and capable of prolonged incandescence without destructive wasting. Carbon has the highest boiling point of all known conductors, but has an unfortunate tendency to evaporate rapidly at temperatures far below its boiling point; hence it cannot be operated at as high an efficiency in incandescent lamps as certain metals of lower melting point, in particular tungsten. Carbon filaments are prepared from cellulose in the form of cotton, which is dissolved to a viscous condition and squirted through dies into smooth threads. The threads are dried, cut to proper lengths, and carbonized by a roasting process. At this stage the filament is fragile and fairly soft. It is next mounted on electric terminals in an atmosphere of benzene vapor and raised to incandescence by a carefully regulated electric current. The heat of the filament decomposes the benzene vapor and causes a shell of hard graphitic carbon to collect on its outer surface and to correct any irregularities in its diameter and resistance. The metallized carbon filament is produced by a process similar to that outlined, but it is treated to a process of baking in an electric furnace before and after the

"flashing process." The physical changes produced by this heat treatment greatly increase the strength, conductivity, and durability of the carbon at high temperatures.

With the general adoption of tungsten metal as a filament material, the use of carbon filaments of both types has very greatly declined. Tungsten has a very high melting point, about 3200° C., and can be heated until fairly soft without rapid evaporation. It is a very dense and hard metal and can be rendered ductile only by an elaborate heat treatment. Before the commercial development of the drawing process for tungsten, filaments were produced from a paste of tungstic oxide mixed with a starchy binder and squirted through a minute diamond die. These threads were chemically reduced to pure tungsten and welded by the passage of electric current into fairly continuous wires. The drawn filaments of the present day are in all respects greatly superior to the early squirted filaments. The conductivity of tungsten is so great compared with that of carbon that the filaments of the former must be relatively long

NITROGEN-FILLED TUNGSTEN LAMP FOR STREET LIGHTING.
1000 candle power.

and of small diameter. As the metal softens perceptibly at its operating temperature, a more elaborate form of mount is required by tungsten filaments than that used with carbon. This takes the form of a double spider of copper wires on which the filament is bent back and forth in short lengths. Series tungsten lamps for street lighting usually have a single loop of coarse wire anchored to the tip of the bulb. The tantalum filament was used in great numbers before the advent of the drawn tungsten filament, but has since practically disappeared. Its

efficiency and life were decidedly inferior to those of the tungsten lamp.

Ordinary incandescent lamps are exhausted by air pumps and by burning in each chamber a small amount of phosphorus compound. The highest practicable vacuum is sought, as slight traces of gas hasten the decay of the filament and serve to conduct away part of its heat in useless form. In some tungsten lamps of recent development a radical departure is made from all previous practice by filling the bulb with nitrogen gas. The gas serves as an active conductor of heat away from the filament and so causes a large element of loss. The gas pressure, however, retards the evaporation of the filament at high temperatures and so makes possible an increase in temperature more than sufficient to offset convection losses of heat. It has not been found possible to improve the efficiency or life of small lamps by this method; hence its commercial development is limited to lamps above 100 candle power. To meet the increased difficulty in supporting the filament due to its softness, a new method of construction is employed. The filament is coiled into a tight helix of small diameter, and the distance between its ends is greatly reduced. The coiled form of filament undergoes less loss of heat by convection than the straight filament in the presence of the gas.

The method of sealing the leading-in wires to the bulb so that the expansion and contraction of the lamp as it is heated and cooled may not admit air is a matter of the highest importance. The sealed portion of the wire is a very short length of platinum, a metal whose expansive action coincides perfectly with that of the glass. Refinements of manufacture have reduced the cost of platinum per lamp to less than one cent.

The following table gives some idea of the great flexibility of the incandescent lamp and the efficiencies of various types:

Type of Lamp	Range of candle power	Useful life (hrs.)	Watts per hor'z'l candle
Carbon	4-32	600	3.1-3.5
Carbon (nitrogen)	15-100	800	2.0-2.5
Tantalum	20-40	800	2.0-2.2
Tungsten	1-500	1000	1.0-1.3
Tungsten (nitrogen)	100-2000	1000-2000	.50-.75

The Nernst Lamp, invented by Professor Nernst of Göttingen, employs as a luminous element one or more rods or glowers of rare earth oxides, chiefly zirconium and yttrium. When cold, these glowers are practically non-conducting, but their conductivity increases greatly when heated. An external heating coil is required to start the lamp in operation. The glowers cannot be operated in a vacuum. The Nernst lamp has gradually declined in use since the advent of the tungsten lamp.

With the developments of modern illuminants of high efficiency, much attention has been given to the artistic and scientific use of lamps. High-efficiency lamps are for the most part of excessive brilliancy and require the use of some kind of diffusing medium to soften the light. In many cases a degree of diffusion approaching that of daylight has been sought by the complete concealment of the lamps within bowls or troughs which reflect the light upward to a white ceiling, whence it is distributed about the room. Semi-indirect lighting, in which the lamps are covered by translucent bowls of glass, which partially transmit the light downward and par-

tially reflect it to a white ceiling, is considered by many a more satisfactory solution of the problem. The various diffusing agencies used with modern lamps absorb from 15 to 40 per cent of the light. Since it is not the total light output of a lamp or the brilliancy of its light which measures its value, but the useful light entering the eye from illuminated surfaces, the softening of the quality of light usually much more than compensates for absorption of light in a diffusing medium. This is especially true in street lighting, where the degree of illumination is low. See PUBLIC UTILITIES.

ELECTRIC LOCOMOTIVES. See ELECTRIC RAILWAYS.

ELECTRIC METERS. There are three general classes of electric meters. The first comprises *indicating meters*, such as are mounted on the switchboards of power stations and those used in making electrical measurements. Such meters show at each instant the voltage, current, power, or power factor in an electric circuit. A second group consists of *curve-tracing meters*, which trace on suitably divided charts ink-line records of the various electrical quantities enumerated above. The third group includes all devices used to record the consumption of electrical energy, technically known as *watt-hour meters*.

Indicating and curve-tracing meters exist in great variety, but their operating mechanisms are of three general types. In the moving-coil type a coil of fine wire is supported on pivots so that it normally stands parallel to a strong magnetic field. When a current flows in this coil, it receives a twisting impulse from the magnetic field which is opposed by a spiral spring so that the actual deflection depends on the strength of the current in the coil. In direct-current instruments of this class the magnetic field is produced by powerful horseshoe magnets, but in alternating-current meters the field is set up by fixed coils without iron cores. In the hot-wire type of instrument a fine wire is stretched between two terminals and is heated by the current passing through it. The wire expands according to the strength of the current and imparts a turning motion to an index needle. This type of meter is equally adaptable to direct and alternating currents. In the magnetic-vane type of meter a fixed coil is set with its axis inclined to a spindle carrying a light vane of iron. As current flows in this coil, a magnetic field is set up which attracts the vane and causes it to turn on its pivot in the endeavor to align itself with the strongest portion of the magnetic field. An instrument of this type may be used with either form of current.

The earliest commercial type of watt-hour meter was introduced by Edison and was based on the chemical action of an electric current. The meter consists of a cell containing a solution of zinc sulphate in which are immersed two electrode plates of zinc. A flow of current through the solution causes zinc to be dissolved

from one plate and to be deposited on the other at a rate in exact proportion to the flow of current. The weight of metal in grams so transferred in any period may be divided by 1.213 to determine the number of ampere hours of electricity which have passed through the cell. The cell usually carries a fixed fraction of the total current, the remainder passing through a German-silver shunt. The number of watt hours consumed is computed by multiplying the ampere hours recorded by the ratio of the total current to that passing through the cell and by the voltage of the circuit. Such a meter is quite accurate if properly compensated for changes of temperature. Its disadvantages are very serious and have practically driven it out of use. It is adapted only to direct current, it cannot be read directly by the consumer, and the labor of collecting and weighing plates is troublesome and costly.

Practically every watt-hour meter of the present day is essentially an electric motor whose shaft is driven at a speed proportional to the power being consumed in the system. The shaft is attached through a train of gears to the pointers of a set of dials, which usually read in tens, hundreds, thousands, and tens of thousands of kilowatts. The type of meter most used on direct-current systems is the invention of Elihu Thomson. It consists of a small commutator motor the field coils of which are of heavy wire and carry part or all of the line current. The armature consists of a number of coils of fine wire wound over a commutator form. Small copper brushes bear on the commutator and serve to connect the armature across the supply mains. The field strength is proportional to the current, and the armature current to the voltage. The torque is proportional to the product of these two or to the power being consumed. The armature shaft carries a light disk of aluminium which it revolves between the poles of strong horseshoe magnets. Foucault, or "eddy," currents are set up in the disk and serve to retard its motion. The resulting speed of revolution is therefore directly proportional to the power, and the total number of revolutions in any period is a measure of the energy or watt hours consumed in that time. The Thomson meter can be used with either direct or alternating current, but it has been largely superseded in systems of the latter type by the less expensive and simpler induction meter.

The induction meter embodies the principle of the induction motor. Its armature consists of a disk of aluminium forming a short-circuited path for currents induced by a revolving field passing through the disk. This revolving field is set up by the interaction of two sets of coils—one highly inductive and connected in shunt across the circuit, the other but slightly inductive and connected in series with the circuit. The current in the highly inductive shunt coils is very nearly a quarter cycle, or 90°, behind the voltage in phase. The magnetizing action of these coils reaches its maximum at a later time than that of the series coils and tends to create a revolving field as in a two-phase induction motor. The revolution of the disk is retarded by horseshoe magnets like those used in the Thomson meter. As the torque on the disk varies as the power in the circuit, and as the retarding force is proportional to the speed, the rate of revolution is directly proportional to the power. Two-phase and three-phase in-

duction meters consist of two single-phase elements acting on a common shaft.

A third type of meter, used to some extent in America and in extensive use abroad, is based on the fact that a current-carrying conductor is acted on by a sidewise force when placed in a transverse magnetic field. The shunt winding of this meter is an electromagnet between the poles of which is a disk of aluminium floating in a shallow chamber filled with mercury. The main current is caused to pass through the mercury chamber from side to side at right angles to the magnetic field. As a result, the mercury and disk are set in revolution. The disk carries a shaft and is retarded in its motion by horseshoe magnets. This meter may be used with direct or alternating currents, but differs from the Thomson type in that it has no wound armature and requires no commutator.

The bearings of watt-hour meters are usually jewels of diamond or sapphire to lessen the friction. The nature of such meters is to run somewhat slower with use, due to increasing friction. Cases where a meter installed in good adjustment subsequently gain in speed are relatively rare. Service regulations in many cities and States require that each meter shall be tested and adjusted not less than once each year and that each meter in service shall be accurate to within 2 or 3 per cent. In many cases the dial reading of a meter must be multiplied by a constant to ascertain the true energy consumption. The value of this constant is often printed on the face of the dial. ELECTRIC MOTOR. See DYNAMO-ELECTRIC MACHINERY.

ELECTRIC RAILWAYS. Railways on which the cars or trains are propelled by electric power, either transmitted from central power stations or supplied by accumulators or storage batteries carried on the cars themselves. The first attempt to build an electric railway of which there is any record was made by Thomas Davenport, a blacksmith and wheelwright of Brandon, Vt., in 1835. For a motor he had a revolving electromagnet running between soft iron armatures or pole pieces, carrying upon the revolving shaft a commutator by which the direction of the current was regulated. Three years later, Robert Davidson, of Aberdeen, Scotland, built an electric locomotive for standard-gauge railway tracks which made several successful trips. In 1850 Prof. C. I. Page, of Washington, D. C., made a 16-horse-power electric locomotive which was tested on the Baltimore and Ohio Railroad and developed speed as high as 19 miles per hour. About the same time Moses G. Farmer constructed a small model electric railway, which was notable for the fact that a reduction gear from the motor shaft to the driving axle was employed, and because the current was supplied to the motor through the rails. All these early attempts at electric propulsion were made previous to the invention of the dynamo, and current had to be obtained from batteries.

In these early attempts it was realized that the expense of generating electricity in chemical batteries was too great to admit of its ap-

plication to propulsion on railways. With the development of the dynamo, and as one improvement and discovery after another was made, the fact was demonstrated that in its use lay the means of producing electrical energy for railway propulsion. It was not until 1879, however, that what may be called the first working electric railway of full size was constructed. This was an exhibition line 1000 feet long, built at the Berlin International Exposition by Siemens and Halske; the motor was a Siemens dynamo connected by double reduction gearing to the axle of a car capable of carrying 20 passengers. In 1880 Thomas A. Edison and Stanley J. Croton, in America, began experimenting, but a contention between them over priority of patents delayed any real results until 1883. Meanwhile Siemens and Halske had constructed a third-rail line in Berlin and an overhead-wire line in Charlottenburg. In 1883 Werner Siemens built a third-rail line 6 miles long from Portrush to the Giant's Causeway in Ireland. Power for operating the dynamo was obtained from a waterfall operating a pair of turbine wheels.

In 1883 the Field-Edison controversy was settled by a consolidation of interests, and an exhibition line 1500 feet in length was installed at the Chicago Railway Exhibition, upon which was run an electric locomotive taking current from a third rail, with joints bonded to improve its conductivity. Later in the same year an overhead line was exhibited in Chicago by C. J. Van Depoele, and about the same time Leo Daft built a third-rail line from Saratoga Springs, N. Y., to Mount McGregor. During this time E. H. Bentley and Walter Knight built a conduit line in Cleveland, Ohio, and later one in New York City and one in Boston.

The first practical overhead-trolley line was built in Kansas City in 1884, in which double overhead conductors were used with a trolley wheel riding on top of the wire. In 1885 Mr. Daft constructed a third-rail line at Baltimore and Mr. Van Depoele installed an overhead-trolley line at Toronto, Ontario. The next step made in the development of the electric railway in the United States, and the one which did most to stimulate capitalists and inventors to the active interest which has produced the marvelous perfection in electric-railway transportation which we witness to-day, was the contract made by the Union Passenger Railway Company, of Richmond, Va., with Mr. F. J. Sprague, to equip its 13-mile system of street railways for electric traction. On Jan. 1, 1888, there were 13 electric railways with 48 miles of track in operation in the United States and Canada. There followed a period of consolidation of interests among electric-railway builders, and the modern era of electric-railway development was opened.

The history of this growth, so far as it is important to outline it, can but be touched upon in the various modern systems of electric railways. For this purpose the subject may be divided into: (1) overhead-trolley railways; (2) conduit railways; (3) storage-battery systems; (4) electric locomotives and heavy-train systems; (5) central station construction and equipment; (6) cars and motors.

Overhead-Trolley Railways. In overhead-trolley lines the current for operating the cars is taken from a suspended wire conductor by means of an underrunning trolley wheel carried on a trolley pole extending upward from the car roof, or, in high-speed lines, by means of an ar-

range of levers called a "pantograph" trolley. The current passes down the trolley-pole conductor to and through the motor and returns to the central station by way of the rails. In a few instances double trolley lines have been constructed on which the second conductor provides

DIAGRAM OF TROLLEY-CAR CIRCUIT.

for the return current. In the three-phase trolley systems, used to some extent in Europe, two overhead conductors are required; for the third conductor the track rails are used.

Trolley-road construction may be subdivided into roadbed and track construction and overhead construction. Only a few salient features of each can be touched upon here. Street-railway tracks when once laid cannot be repaired without taking up the pavement; and as this is an expensive operation, great care is taken in first putting down the tracks. Modern practice for city work where traffic is heavy is to use standard oak ties 8 feet long and impregnated with some preservative. A 9-foot trench is excavated and the ties are spaced 2 feet on the centre. Sixty-foot rails, weighing sometimes as high as 114 pounds, are spiked in place, and ballast is dumped and tamped under the ties until the rail heads are approximately at grade. Concrete is then filled in between and around the ties and to such a point above them as will leave space for the paving. The final leveling of the rail is done just before the concrete is put in place, so that the setting of the concrete will aid in maintaining the grade. If the joints have been electrically welded, engineers claim that such construction should need no repairs for from 12 to 15 years. Splice joints for electric railways resemble those of steam railways and consist of two splice plates for each joint, which are placed on opposite sides of the two rails and clamped together by bolts passing through both splices and rails. The method of making cast welded joints is as follows: The rails at the joint are cleaned and brightened by a sand blast (q.v.), and a casting mold is placed around the rail ends, making a tight fit. Into the mold the molten metal is poured. The metal in contact with the mold begins to cool and forms a crust, while the interior remains in a molten state. This crust continues to cool and at the same time contracts, forcing the molten metal towards the centre of the joint. The top or bearing surface is afterward filed off perfectly smooth, so that it is difficult to detect a joint by riding over it. Some engineers object to the cast welded joints because the mass of metal surrounding the joint makes it impossible to place a tie directly under, and when the joint is hung between two ties, the constant hammering of the car wheels causes a dish in the rail at this point. Electric welding of rail joints is described in the article on WELDING, while under ALUMINO-THERMICS is discussed

that process of welding as applied to electric-railway rails.

The rails being laid and the jointing and bonding finished, the pavement is laid, restoring the street to its original condition. For suburban and interurban roads a track built of from 60-pound to 100-pound T-rails spiked directly to the ties is used, the road surface being restored after all is completed.

Overhead construction for trolley roads comprises the electric conductor and the structures for carrying the conductor. The supporting structure for the conductor is of two forms, usually called span wire and bracket arm. In the first the trolley wire is hung from a span wire stretched between poles on opposite sides of the track; in the second, a single row of poles is used with a bracket arm extending out over the track to carry the conductor. Often double-bracket poles placed between the tracks carry the two conductors for double-track roads. Both wood and iron poles are used, while special poles of reinforced concrete have been tried with some success.

A special form of catenary construction is employed on systems using trolley voltages over 1000. A steel messenger wire supported by bracket arms or span wires hangs over the track in a series of flat catenary curves. The trolley wire of copper is suspended from the messenger wire by metal hangers at short intervals. These hangers are accurately graded in length so that the trolley wire is at all points parallel to the track and of very nearly constant flexibility. This type of construction insures continuous contact between the trolley wire and the current-collecting device at high speeds and lessens the danger of accident from trolley-wire breakage.

In America the development of overhead construction has been in the direction of securing lightness, strength, and effectiveness at low cost, and ornamentation has not been sought. In Great Britain and continental Europe, however, fancy brackets, scrolls, and ornamental castings have been used very generally, and this is the essential difference between the practice on the two sides of the ocean. Car and central-station construction are described in succeeding paragraphs.

Conduit Electric Railways. Conduit electric railways are those having some form of conduit or trough below the level of the rails, either between them or at the side of the track. Usually there is a continuous opening or slot in the street, through which the "plow" projects from the bottom or side of the car. In the conduit, supported upon suitable insulators,

the slot on a wire imbedded in the plow, through the motor, and again back to the other conductor. Various other kinds of conduit systems have been devised, but the one described is

CROSS SECTION, SHOWING FORM OF YOKE AND TRACK CONSTRUCTION.

the only one which has reached any commercial success. The conduit electric railways of New York and Washington, e.g., have the conduit between the rails, while the only side-conduit railway of importance is that at Budapest, Hungary.

As constructed in America, a trench about 2 feet deep at the centre and 6 feet wide is dug along the line of the road, and heavy cast-iron yokes, weighing from 400 to 500 pounds, are placed crosswise of this trench about every 4 feet. To these yokes are bolted the tracks and the rails forming the edges of the slot. Between these yokes and around them is placed concrete, with a trough in the centre to form the conduit.

Between and at the sides of the tracks at intervals of about 15 feet small covered openings are made into the conduit, and at these points heavy cast-iron and porcelain insulators are bolted to the slot rails. These have pins projecting down into the conduit, to which steel T rails are bolted. The car plows extend through the slot and have rubbing blocks which press against the conductor rails. Current is supplied to these conductors by feeders or cables which run in underground conduits alongside the track from the power station and are attached at intervals to the conductor rails. Drainage is secured by frequent outlets from the conduits to sewers, and manholes at intervals give access to the conduit for repairs. Conduit railways are far more expensive to construct than overhead-trolley lines, chiefly because of the elaborate track and conduit construction required, and because of the necessity of removing underground pipes which interfere with the conduit. The most notable conduit electric railway systems of the United States are those of New York City and of Washington, D. C., the New York system aggregating over 200 miles of line.

Third-Rail System. In this system, the current is conducted to the cars by means of a third rail, placed on insulators about 20 inches from the track rails. For this purpose an ordinary T rail is used, with the joints carefully bonded. This rail is connected at convenient points with the feeders from the generating station or transformer stations. This system is used on all the elevated roads and subways or underground tubes in the United States and also on many interurban roads as well as in underground tunnels, terminals, and suburban zones of such American systems as the New York Central and Pennsylvania, where electrification has been introduced. Current is taken from the rail by sliding iron contacts called "shoes" mounted on the car or locomotive. The amount of current

CROSS SECTION OF CONDUIT OF ELECTRIC RAILWAY, SHOWING THE METHOD OF SUPPORTING THE CONDUCTOR RAILS.

pins, or brackets, are the conductors, against which suitable rollers or rubbing blocks, forming part of the plow, are pressed. In this way current can be taken from one conductor up through

that can be taken from a third rail through a single contact is much greater than can be taken from the overhead trolley; hence the extensive use of this system on heavy traction roads.

Storage-Battery Systems. Numerous attempts were made in the early days of the art to operate electric-railway cars by means of storage batteries carried in them, but none of these attempts met with commercial success. Perhaps the most notable experiment of several made with storage-battery traction in the United States was that carried out on the Fourth Avenue Railway in New York City in 1890. Fourteen cars were equipped with 110 cells each, 55 on each side of the car, under the seats, and were run between the post office and the charging station at Eighty-sixth Street, about 5 miles. The result of these experiments led the officers of the road to conclude the system impracticable, owing to the great cost of depreciation of the batteries. The advent of the Edison nickel-iron battery later led to more successful experiments in battery propulsion. This battery is very rugged and relatively light and is capable of very rapid charging. In 1914 a considerable number of battery cars were in use in New York City, particularly on lines where the traffic did not warrant the outlay for installing an underground conduit system or where temporary service was required.

Storage batteries, however, find a more important use as regulators in connection with the trolley or third-rail systems of propulsion, being installed in the generating station or substation of the system to prevent heavy fluctuations of load on the generators. Such batteries have been installed on a large scale on some of the largest street-railway systems of the United States, notably the Metropolitan Traction Company's conduit lines in New York City and the South Side Elevated Railway in Chicago, Ill. The New York Central Railroad utilizes an installation of storage batteries for its electric system aggregating in capacity over 20,000 kilowatts.

High-Voltage Systems. The early electric traction systems employed exclusively direct current at voltages not exceeding 600. As the extent of these systems and the volume of their power requirements increased, the cost of conductors for transmission at so low a voltage tended to become prohibitive. To maintain the advantages of centralized power supply and to make possible electric operation over long distances, it became the practice to generate alternating current and to transmit it at high voltage to substations, where it was converted into direct current at about 600 volts for the use of the local section of the trolley system. (See POWER TRANSMISSION.) This system of power supply is still very extensively used. The single-phase alternating-current system grew up, first in Europe and later in America, as a rival to the composite system just described, especially in the realm of main-line and interurban railways. In this system the trolley wire is supplied with alternating current at a voltage of from 3000 to 15,000. Current is taken off at the car or locomotive by means of a wheel trolley or a sliding contractor and is reduced in voltage by a transformer and controller before being applied to the motors. The alternating-current motors are also capable of operation by direct current; hence the urban sections of single-phase railways are usually

supplied with direct current at 600 volts or less. The advantage of the alternating-current system is the elimination of expensive substations and the high efficiency of the transmission system. The motors are in many ways inferior as motive power to those of the direct-current type. For these reasons the single-phase system has found its field on heavy railways and on long interurban systems where the power-transmission problems are predominant. A number of European trunk lines and the Great Northern system in America make use of three-phase induction motors. These are very powerful and rugged and can be operated with great economy in transmission, but they require a complex double-trolley system and are unsuited to service with frequent stops.

In recent years American engineers have given a great amount of attention to increasing the trolley voltage in direct-current systems. A number of lines now employ 1200 volts and some 2400. Still higher voltages are considered feasible. In these systems the motors are insulated for full voltage, but are usually operated in pairs so connected that each receives half-line voltage. The number of substations required is very much less than for 600 volts. To secure the economies in transmission afforded by the single-phase system in combination with the advantages of direct-current motors, numerous experiments have been conducted with locomotives carrying current rectifiers of large capacity—in some cases mercury-arc rectifiers and in others rotary converters—and driven by direct-current motors. No such systems have yet been commercially developed.

Cars and Motors. One or more electric motors geared to the car axles and a controlling switch on each platform constitute the principal parts of a motor-car equipment. Instead of having the journal boxes attached to the car frame, as in horse cars, the motors and running gear are attached to a car truck, on which the car body rests. The remarkable improvement which has been made in the design of street-car motors within the last 20 years is the principal cause of the success of electric railways. The first car motors were entirely too light mechanically and of too small capacity. From a single 15-horse-power motor driving one car axle, the capacity of the car equipments has been gradually increased up to the present practice of using four motors, one geared to each axle, for ordinary urban service. These motors are of various horse powers, from 25 for light service up to 225 for high-speed interurban lines. A marked improvement has also been made in the reduction of armature speeds, so that the use of a double reduction in speed by means of a countershaft and two pairs of gears between the armature shaft and the car axle is now obsolete. Gearless motors, in which the armature is built on the car axle, have been introduced but single reduction motors having the armature shaft geared directly to the car axle are the most commonly used at present. Almost all modern car motors are of the multipolar type instead of the bipolar, as formerly, and the reduction in armature speeds is due to this change of design. The severe service to which street-car motors are subject has led to making them very substantial in design, in order to avoid mechanical injury, and so-called iron clad motors, in which the field magnets form a closed iron box, are almost exclusively used to

prevent short-circuiting by water, or by nails or scraps of iron picked up by the magnets. Most of the single-reduction four-pole motors are supported on one side on the car axles by journals set in bushings at each end of the motor frame, the motor shafts being parallel to the car axles. The opposite sides of the motors are connected to the frame of the car truck by means of springs, and a pinion on each armature shaft meshes with a gear wheel on either axle. The function of the springs is to avoid a shock on starting the car, by permitting the motors to turn through a small arc about the axles. In gearless motors the armature shaft is a hollow tube, through which the car axle passes, and to which it is flexibly connected by means of springs. A number of attempts have been made from time to time to connect the armature shaft and the axle by belts, sprocket chains, friction clutches, etc., none of which has been able to stand the service. The latest improvement in street-car motors is the development of the alternating-current single-phase motor. See DYNAMO-ELECTRIC MACHINERY.

Controlling Systems. The starting and regulation of speed of a single car are effected by means of the controlling switches on the car platforms. The methods of regulation of the different electric-railway systems are too numerous to be described in detail, but the same general plan is common to them all. With the direct-current system series motors are always used, and the field windings are wound in a number of separate sections, the ends of which are carried to contact pieces in the controlling switches. In addition to the resistance of the field winding a resistance box is also used. The contact pieces in the controller press against strips of metal plates, each row of which is connected so as to vary the current drawn from the motor. In starting the car the resistance box, sections of the field coils, and armature are all in series to prevent a too large passage of current through the armature. The next turn of the switch cuts out more or less of the resistance-box circuit, allowing more current to pass, and by successive movements of the switch the field coils pass through various combinations, from all in series to all in multiple, the latter corresponding to the highest car speed. To stop the car, the switch is reversed, making the same combinations in reverse order. To change the direction of the car, a separate switch is generally provided, which changes the direction of the current through the armature with reference to its direction through the fields. Where there is no commutation of the field coils, the changes in speed depend entirely upon the variable amounts of extra resistance thrown into the circuit.

Multiple Unit Control. In operating trains of several cars at high speed, and yet making many stops, as on the elevated roads in New York and Chicago and various underground lines, at least every other car of the train is equipped with motors, and the several motor-car equipments are operated simultaneously. This is accomplished by the so-called multiple-unit system of control, invented by F. J. Sprague. There are a number of systems of this sort in use, but all embody the same general principles. On each motor car is a group of switches and resistance grids which control the current flowing to the motors on that car.

This controller is operated from a distance by means of electromagnetic or electropneumatic devices controlled by circuits called pilot circuits, which circuits are connected to a master controller operated by the motorman. All the pilot circuits on all the cars are connected to form a "train line"; cars not equipped with motors must nevertheless be equipped with this line and the necessary cable couplers, so as to complete the line for the entire length of the train. This line is connected to all motor controllers or contactors on the train, and to a master controller on each car, so that all the motors on the train can be operated from any car.

Electric Locomotives. An electric locomotive is a much simpler structure than a steam locomotive and can usually be designed to develop much greater power for the same weight. In many respects both have the same limitations, in that the maximum tractive effort or drawing power is fixed by the adhesion of the rims of the driving wheels to the track. Electric locomotives differ in type according to the method of power supply and type of motor used (as described in preceding chapters), according to the method of power transmission, and according to the mechanical power transmission from the motors to the driving wheels. There are three common methods of motor support. The simplest is that in which the motor armatures are keyed directly to the driving axles and are permitted vertical play by the use of flat pole faces. In a second method the armature is supported on a quill or hollow shaft supported by helical springs. In the third method the motors are carried on the side frames of the locomotive and are therefore not limited in size by the small space available on the trucks under the floor. When the motors are frame-mounted, the mechanical transmission of power may be through pinion and gear or by a system of cranks and connecting rods resembling somewhat those used on steam locomotives.

The 1913 type of locomotive used on the New York Central system is 57 feet long and weighs 110 tons, all of which is carried by driving axles. There are eight motors, each of 325 horse power, with their armatures mounted directly on the axles. There are eight driving axles, grouped in four trucks. The two end trucks are of the bogie type and act as guides. The two middle trucks are articulated or hinged together so as to turn freely within certain limits, yet give great stability. The power supply is by direct current at 650 volts, obtained from a third-rail system. All the accessories of a steam locomotive are provided, viz., air compressors for brakes, whistle, bell, sanding device. A small boiler is provided to furnish heat to the train. This locomotive is capable of hauling a train of 1200 tons at a speed of 60 miles per hour on a straight level track.

The locomotives of the New York, New Haven, and Hartford system are excellent examples of the single-phase type. The earlier locomotives consisted of a twin unit, each with four motors of 250 horse power with their armatures on quills surrounding the driving axles. The later locomotives are of single-unit construction and have eight motors mounted in pairs on the side frames of the locomotive. Each motor is of

170 horse power. Each pair of motors has its two pinions meshed with a common gear wheel which is carried by a quill surrounding a driving axle. The flanges on the ends of the quills are connected to the driving wheels by helical springs.

The large direct-current locomotives used in the New York terminal system of the Pennsylvania Railroad afford an excellent example of the type of construction of frame-mounted motors and side-rod drive to the drivers. Each locomotive is a twin unit with a total weight of 166 tons. Each section of the locomotive has a 2000-horse-power motor driving four 68-inch wheels. Power is obtained from a third-rail system at 650 volts.

Since the early days of electric locomotives much attention has been given to the development of self-contained motor cars, but their use did not become extensive prior to 1907, when the present type was developed. In its present form the motor car carries a six-cylinder gasoline engine of from 50 to 100 horse power which drives a direct-current electric generator at constant speed. The output of the generator is supplied to series motors mounted on trucks. Cars of this type are independent of power stations and transmission systems. Their operation is much below that of a steam locomotive service, and they can be operated in many cases where steam service entailed a constant loss. See RAILWAYS.

Central-Station Equipment. A railroad power station is usually located as near as practicable to the centre of the system to gain economy in power transmission. Small city systems are generally supplied by direct-current generators. The more extensive systems employ polyphase alternating-current generating plants in conjunction with converting substations for local direct-current distribution. Many large railway systems make it a practice to obtain power from central stations, but maintain their own substations for the conversion of alternating to direct current. The size of the power station required by a railroad system depends on the number and weight of the cars to be operated and the grades to be surmounted. When the road operates 10 cars or less, it is customary to provide about 40 horse power of capacity per car. In the larger systems the heaviest demands of different cars and of different sections of track do not coincide, and a capacity of 20 horse power per car suffices. The power-station capacity required for main-line railroads and terminals is carefully predetermined by an elaborate study of train movements to determine the power requirements of each train and of the entire system from moment to moment.

Important Electrifications. The most important electrified main lines in the United States are the New York, New Haven, and Hartford Railroad (New York to New Haven, Conn.), the New York, Westchester and Boston Railroad, and the Hoosac Tunnel of the Boston and Maine Railroad, all using the single-phase alternating-current system; the Grand Central terminal system of the New York Central Railroad; the New York terminal system of the Pennsylvania Railroad; the Baltimore tunnel of the Baltimore and Ohio Railroad; and the Detroit River tunnel of the Michigan Central Railroad,

all using third-rail direct-current systems at 750 volts; the Cascade tunnel of the Great Northern Railroad, using the three-phase alternating-current system; and the Butte, Anaconda and Pacific Railroad, using the 2400-volt, direct-current system. The most important main-line electrifications in Europe are operated by the single-phase system.

Economics of Electric vs. Steam Roads. It was not until 1913 that a steam railroad was electrified purely for reasons of economy. The reasons which have been compelling in the electrification of steam railroads both in the United States and in Europe have generally been the desire to eliminate smoke and noise in terminals, to add to the pleasure and comfort of suburban travel, to permit of more frequent suburban service, to comply with city ordinances, or to add to the safety and comfort of the operation of trains through tunnels. While electrical engineers have demonstrated on paper that operation by electricity on a third rail or overhead trolley is more economical than operation by steam, actual practice had not, up to 1914, borne out this contention. The economies which electrical operation should effect are a reduction in the wage account, a reduction in the fuel cost, an elimination of the cost of maintaining fuel and water stations, an elimination of the cost of water supply, and a reduction in the cost of repairs per unit of equipment.

To offset these economies there is the added cost of the interest charges on the electrification expenditures and the added cost of the maintenance of the third-rail or trolley system, together with certain added costs of the maintenance of other property due to the action of the electric current.

The economies have never been fully realized in practice, either in the United States or Europe, because up to 1914 no steam road had been so completely changed over from the former method of operation as to permit of the entire abandonment of water stations, etc., and of steam locomotives. Furthermore, the general experience of railroad managers has been that it has not been possible to cut down the labor cost. The pressure which the brotherhoods of locomotive enginemen and firemen have been able to bring to bear on the management has been such that they have had to maintain the same scale of wages for enginemen and the second men on electric locomotives as was paid on steam locomotives. The management of the New York, New Haven, and Hartford, which has had the most extensive experience among American railroads with electrical operation, is of the opinion that, if they can entirely eliminate operation by steam locomotives for both freight and passenger service between New Haven and New York City, their cost of operation will be lower with electricity than it would have been if steam operation had been continued and used exclusively.

Electrical engineers have contended that it was especially in operation of trains over heavy grades that electrical operation could effect the greatest economies. In the latter part of 1913, however, a very careful study of the possibilities of saving by the electrification of the Atchafalaya, Topeka, and Santa Fe's line over the continental divide at Raton Mountain, N. Mex., was made, and the conclusion arrived at was that electrical operation would probably be more expensive,

when the interest charges on the installation were taken into account, than is steam operation. In this study it was estimated that the cost of the electrification of the 30 miles of line would be about \$2,000,000, and that the saving in annual cost of operation would be about \$60,000, or in the neighborhood of 3 per cent on the investment.

The Economics of Electric-Railway Operation. The various types of electric railways, the construction and operation of which have been described, may be classified, as to use, as street railways, interurban railways, either operating on the public highways or on a private right of way, and so-called electrified steam railroads.

Street railways in the United States, Canada, and Europe are, with few exceptions, operated by electricity. In the larger cities the underground contact is generally prescribed by law, and in the smaller cities overhead trolleys are used. Street railways properly include roads operated on an elevated structure above the streets or in subways underneath the streets. (For an engineering description of the features of subways, see TUNNELS.) A very considerable portion of the street railways in the larger cities of the United States between the years 1900 and 1913 passed through either a financial reorganization or actual receivership proceedings or a foreclosure sale. The causes for these financial difficulties were, in general, the change from horse-car and cable operation to electrical operation, and from overhead to underground trolley systems, and from one kind of equipment to another, all of which necessitated the abandonment of property which had not been worn out and which had a comparatively small scrap value. This property had not been covered by previous charges for depreciation or obsolescence. Another cause was the rapid amalgamation of various lines into one company, with an accompanying reduction of the promoters' hopes for the elimination of competition and the advantages of combined management and closely allied to this were the large transfers which required universal transfers. The bankruptcy of the street-railway lines of New York City well illustrated the working of all of these causes, the relative importance in the New York City case being indicated by the order in which the causes have been named. It was shown in one of the court proceedings that on one cross-town line only one passenger in about 20 paid a cash fare, the other 19 riding on transfers, many of which would be used for one or two additional rides.

Short-haul traffic is, of course, the most profitable business that street railways can do, and surface lines have a very much greater proportion of short-haul traffic than either elevated or subway lines. On the other hand, elevated lines and subway lines do not transfer, except in certain cases, and then usually only upon payment of something additional. The passenger journey, therefore, is necessarily continuous. It has been the experience of New York, Boston, and Chicago, that the transfer privileges required by city ordinances more than offset the apparently shorter average haul, so that, although the average haul is longer on the elevated or subway than on the surface lines, the elevated and the subway both showed more profitable operation than the surface lines. There are, of course, a great number of other

factors which enter into a comparison such as this—length of train, cost of maintenance, etc.—but it is generally conceded that the transfer privilege is far and away the most important factor.

The best unit of comparison of earnings and expenses of street railways exclusive of elevated and subway lines is the car mile. This, however, is open to many of the objections that the train mile as a unit in steam railroad operation is. It is not a real measure of work done. The cost per car mile may be somewhat increased by the use of larger and faster cars, while the number of passengers carried per car may be so increased by these changes as to more than offset the increase in expenses.

The common American practice in regard to subways is to have the city lend its credit, at least in part, to the construction company which builds these subways and to take a first lien on earnings to see that the interest charges which the city has guaranteed are paid; to lease the subways to an operating company for a term of years under such terms as will permit, presumably, of the operating company paying off its funded indebtedness at the expiration of the lease and the reversion to the city of the subway at the end of the period of lease, with some provision for the purchase of the equipment in use at the expiration of the lease.

The above discussion, of course, applies only to the street railways of the large cities. The street railways of the smaller cities and towns are, in a very great number of cases, under the management of holding companies which also control gas and electric-lighting plants. Holding companies for these railways have in many instances been formed which control and direct the management of public-utility corporations in a number of widely separated towns and cities. It is quite impossible, therefore, to gauge accurately the earning capacity of street railways in the smaller towns and cities, because the results of their operation are combined with the figures showing the result of the operation of gas plants and of electric-lighting plants and also, of course, in many instances, of interurban railways.

In the United States the very rapid development of public utilities in the decade 1903-13 called for the investment of a vast amount of capital, which in these enterprises commanded a higher rate of interest than it could have got if invested in steam railroads or municipal or other government securities. In the great majority of cases local capital was raised for the original construction of a part, at least, of the public-utilities plants. Liberal franchises were, of course, granted, and there was in some instances competition, as, e.g., between two or more different street railways, or between a gas company and an electric-lighting plant. The competition led to the desire for consolidation and construction profits; the possibility of increased earnings led to the desire for further extension and therefore to the invitation of outside capital. The enterprises being speculative in character, bankers who furnished this capital and effected consolidations took liberal commissions, and the securities were sold to investors to yield, for bonds about 5½ to 6 per cent, for preferred stock about 7 per cent, and for common stock usually the hope of large profits through the increase of market value of the stock.

Public utilities of this kind are natural monopolies, but, on the other hand, the earnings of street-railway companies are limited by the cost of charging, at least in the United States, more than a five-cent fare, regardless of the length of the ride; thus, the Interborough Rapid Transit charges but five cents from Flatbush Avenue, Brooklyn, to Van Cortlandt Park, at 242d Street, a distance of about 14 miles. To earn the returns on the investment which are necessary to induce new capital to come into enterprises of a somewhat speculative nature, strict economies of operation have been necessary as well as the rapid growth of population. See PUBLIC UTILITIES, REGULATION OF.

Interurban Electric Railways in some instances have afforded transportation service to territories wholly without facilities before, but in the majority of cases the transportation facilities afforded by electric interurban railways have been in addition to the facilities already furnished by steam railroads. The reason for this, of course, is obvious. A steam railroad carrying freight can be built through very long stretches of territory in which there is a sparse population, since it can depend for the bulk of its earnings on its through-freight business. Electric roads are dependent almost entirely on local business, since they cannot compete in cost of service for through business over long distances with steam railroads, even where the steam road has the more circuitous route. The electric road must be built where the population is already fairly thick, and population has developed along the lines of the steam roads. With frequent and cheaper service the electric can compete quite successfully for passenger business with a steam road up to about 25 miles. For a longer haul than this the greater speed of the steam road apparently outweighs the consideration of frequency of service and of lower cost per mile with the great majority of travelers. It was at first believed that electric express service could compete with steam roads between large cities not more than 100 miles apart, but the majority of such electric roads have not been particularly successful. A good instance of this is the Chicago and Milwaukee, which was built at considerable expense with the idea of doing both freight and passenger business, but which went into the hands of a receiver in 1910 and in 1914 was not yet operating at a profit sufficient to pay the interest ordinarily demanded by investors in electric-railway securities on the original cost of its construction.

The influence of electric railways on steam roads which are paralleled is interesting. At first there is a very large falling off of passenger rates on steam roads. The added transportation facilities, however, not only induce more traveling, but add to the attractiveness of residence in the country served by these roads. This induces additional settlement, and after a few years the steam road makes up in long-haul passenger business a part of its loss in local business and in addition gets an inbound and outbound merchandise freight business that in part compensates it for the local passenger business taken away by the electric.

Passenger rates on interurban electric railways vary from three-fourths of a cent to a cent and a half per mile. This compares with two cents to three cents, the prevailing passenger rates on steam roads. Louis Fischer, in

his book on the *Economics of Interurban Railways*, claims that the approximate average earnings of an interurban railway operating from one large town out through a town and village population is about \$10 per capita of intermediate town and village population, regardless of the size, within certain limits, of the primary city terminal. Where the road runs between two large cities, the earnings, in the neighborhood of \$10 per capita of intermediate population, will be increased by from \$6 to \$20 per capita of the secondary terminal where this secondary terminal is 40 miles or less away from the primary terminal.

ELECTRIC RAY. See ELECTRIC FISH; TORPEDO.

ELECTRIC TELEGRAPH. See TELEGRAPH.

ELECTRIC WAVES. See ELECTRICITY.

ELECTRIC WELDING. See WELDING.

ELECTRIDES, ê-lék'tri-déz (Lat., from Gk. ἤλεκτρίδες, *Elektrides*, from ἤλεκτρον, *elektron*, amber). The Amber Islands of Greek mythology, situated at the mouth of the Eridanus, a large river which was identified with the Po, because amber was found at the mouth of the latter. The name was applied also to islands on the northern coast of Europe. See AMBER.

ELECTROBALLISTICS. The science of measuring the velocity of projectiles by means of electrical instruments. Velocity may be measured, both inside and outside the bore of the gun, at predetermined points in the path of the projectile. The makes and breaks of electric circuits at these points are recorded, as a function of time, by the instrument. See BALLISTICS.

ELECTROCARDIOGRAPH. See PULS-METER.

ELECTROCHEMISTRY, GENERAL. The branch of general chemistry that deals with chemical changes producing, or caused by, electrical energy. The growing industrial applications of electricity are rendering the science itself more and more important every year. Another title of electrochemistry to general interest consists in the fact that the phenomena it deals with have long formed a bond between two great branches of human knowledge—physics and chemistry—the science of the various forms of energy and the science of the various kinds of matter.

The bond may become even more intimate if the comparatively recent hypothesis, according to which electricity itself is a subtle form of matter, turns out to be in agreement with facts. This hypothesis is briefly as follows: Electricity consists of two chemical elements whose atoms, termed "electrons," have exceedingly small (perhaps zero) relative weights: the atoms of positive electricity, or "positive electrons," may be denoted by the symbol \oplus ; the

atoms of negative electricity, or "negative electrons," may be denoted by the symbol \ominus . Like the atoms of hydrogen, electrons of either kind are univalent, so that, e.g., an atom of hydrogen when in the ionic state (i.e., when charged with electricity) is combined with a single positive electron, forming the molecule $\text{H}\oplus$, while an atom of oxygen in that state forms the molecule $\text{O}\ominus$ (just as water is HOH). When not thus combined with the atoms of other elements, electrons may possibly form neutral molecules $\oplus\ominus$. The substance made up of such molecules may have appreciably no weight, may be a nonconductor, and may be capable of electric polarization; and it is worthy of note that these are precisely the properties attributed to the luminiferous ether. While this hypothesis renders Faraday's law of multiple proportions and may certainly be helpful in fixing on the mind a somewhat definite image of the mechanism of electrical processes, it can hardly be said yet to rest on a sufficient foundation. Whether it should be accepted or not will have to be decided on the principle expressed, some years ago, by Poincaré: "It is nonsense to ask of a theory, 'Is it true or false?' The question can only be, 'Is it fruitful or not?'"

At any rate, the electron hypothesis must not be allowed to confuse our conception of *electrical energy* and its relations to other forms of energy. The term "energy," when properly used, designates the cause of any action that is actually taking place, or that is capable of taking place, in a given system. Thus, we may speak of the energy of a falling body, and even of a body suspended at a certain height from the earth's surface; for such a body, if released, *would* fall to the earth. Similarly, we may speak of "electrical energy" whenever a transport of electricity from one point to another is possible in a given system. Energy of every known form can be resolved into two factors—a "capacity factor" and an "intensity factor." In the case of electrical energy the capacity factor is generally known as "quantity of electricity," the intensity factor as "potential difference." Just as in the case of a suspended body the amount of gravitation energy is the greater, the greater the mass of the body and the greater the difference of level between the body and the earth's surface, so in the case of a possible flow of electricity the amount of electrical energy is the greater, the greater the quantity of electricity and the greater the difference of potential between the two given points. Whatever be the ultimate nature of a mass of matter, gravitation energy is still a form of energy. Similarly, whatever be the ultimate nature of a quantity of electricity—whether electricity be a kind of matter or not—electrical energy is still a form of energy, capable of being transformed into kinetic energy, chemical energy, etc.

Electrochemical Reactions. A system in which chemical energy is transformed into electrical is termed a galvanic or voltaic cell, and a combination of two or more cells is termed a galvanic or voltaic battery. One of the first questions that naturally suggest themselves to the student of electrochemistry is, What are the characteristics of those chemical changes whose energy may assume the electrical form? In other words, What chemical reactions can

be utilized for the construction of voltaic cells? The answer is, *All changes, and only such changes, in which acids, bases, or salts take part, or may be caused to take part, can be employed* (see DISSOCIATION). Substances of these classes are termed "electrolytes," and they are usually employed, in cells, in the form of aqueous solutions, in which their molecules are assumed to be dissociated into fragments, termed "ions" (see DISSOCIATION), that are charged with either positive or negative electricity. In most cells the chemical action consists, on the one hand, in the solution of one of the metallic electrodes, its particles entering the solution in the form of ions, and, on the other hand, in the deposition upon the other electrode of another metal, whose particles formed the ions of the solution. For example, the Daniell cell consists, on the one hand, of a zinc electrode immersed in a solution of zinc sulphate, and, on the other hand, of a copper electrode immersed in a solution of copper sulphate, the two solutions being in contact, and the two metals being connected by a metal wire; the chemical action of the cell consists, on the one hand, in the entrance of zinc into the solutions in the form of zinc ions, and, on the other hand, in the deposition, on the copper electrode, of copper ions in the state of metallic copper. The two simultaneous changes evidently ensue in the system at two separate points connected with each other by a suitable conductor of electricity. This "chemical action at a distance" is an essential characteristic of electrochemical action.

An excellent example of common changes in which electrolytes may be caused to take part, and which may thus be turned into a source of electric energy, is presented by the mere flow of hydrogen or oxygen gas, at constant temperature, from places of higher to places of lower pressure. If, say, hydrogen gas is contained in two separate vessels under unequal pressures, a flow of gas will naturally take place from one vessel into the other if communication is established between them. But the equalization of pressures can also be caused to take place as follows: Let two bars of platinum coated with "platinum black" (finely divided platinum, which has a great capacity for taking up gases) be half immersed in a dilute solution of sulphuric acid, while the other halves are exposed to hydrogen gas contained in two vessels, under two different pressures; on connecting the platinum bars outside the solution by a metal wire, it will be found that a current of electricity passes through the latter, while hydrogen passes through the solution until the pressures in the two vessels have been equalized. The action thus taking place is as follows: in dilute aqueous solution the molecules of sulphuric acid are broken up into electropositive hydrogen ions H and electronegative ions SO_4 ; neutral hydrogen molecules from the vessel of greater pressure enter the solution in the form of hydrogen ions and, replacing the free hydrogen ions of the acid, drive them from the solution in the form of neutral molecules into the vessel of lower pressure. Evidently here, too, as in the case of any other voltaic cell, the electric current is caused by ions taking part in the change.

Electromotive Force. We can now discuss the question as to what determines the electromotive force of a voltaic cell, i.e., the difference

of potential existing between its two electrodes. It was once believed that a considerable difference of potential is established whenever two different metals are placed in contact with each other; but this is now positively known to be wrong. If differences of potential arise from the communication of the electrodes outside the solution, those differences are certainly very small and need not be taken into account. In the case of cells with two different solutions (like the Daniell cell), a difference of potential is known to exist at the surface of contact of the two solutions; but this, too, is comparatively small. The main difference of potential in a cell must therefore be seated at the surfaces of contact between the metallic electrodes and the electrolyte solutions, i.e., at the places where ions form and disappear. But how are differences of potential established there? A clear answer to this question is furnished by modern electrochemical theory. If a liquid is placed in a closed vessel, its vapor gradually attains a maximum pressure which balances the vapor tension of the liquid at the given temperature. Again, if an excess of sugar is placed in some water, the sugar dissolves, or, so to speak, vaporizes into the water, and the portion dissolved gradually attains a maximum "osmotic pressure" which balances the "solution tension" of sugar at the given temperature. Similarly, if a metal is brought in contact with water, its ultimate particles tend to rush into the volume of the water until a maximum osmotic pressure has been attained. Since, according to the theory of electrolytic dissociation, the free particles of a metal in solution are invariably charged with positive electricity, the osmotic pressure of a metal in solution can evidently be exerted only by its electropositive ions. Supposing, now, that a bar of some metal is placed in a solution of *one of its salts*, and remembering that the salt is dissociated into metallic and acidic ions, we readily distinguish three possible cases; viz., the osmotic pressure of the metallic ions may happen to be greater than, less than, or equal to, the maximum osmotic pressure that would balance the "electrolytic solution tension" of the metal.

In the first of these cases some ions will tend to precipitate themselves upon the metal bar, just as some of the vapor of a liquid would tend to condense if its pressure exceeded the vapor tension of the liquid; and the force driving the ions out of solution will evidently be the excess of their osmotic pressure over the solution tension of the metal. As soon, however, as a single ion is precipitated out, the metal bar is rendered electropositive, while the solution is rendered electronegative; the newly created excess of electropositive ions; for before the immersion of the metal bar the electropositive and electronegative ions in solution are precisely equivalent. (See DISSOCIATION.) But this means that a difference of potential will have been created between the metal bar and the solution. Henceforward every electropositive ion driven towards the metal bar by the excessive osmotic pressure will encounter a double force driving it back into solution, viz., the electrostatic repulsion of the positive bar and the electrostatic attraction of the negative solution. Finally, when a certain number of ions have been precipitated out, the double electrostatic counterforce will have become equal to the excess of osmotic pressure,

and then, equilibrium ensuing, the maximum difference of potential possible under the given conditions will have been established between the metal bar and the solution. This will obviously be the greater, the greater the osmotic pressure (i.e., the concentration of ions in the solution), and the less the specific solution tension of the metal.

Passing now to the second of three possible cases, viz., the case in which the osmotic pressure of the metallic ions is less than the specific solution tension of the metal, we see that in this case molecules of the metal will enter the solution in the form of positive ions, rendering the solution electropositive and leaving the metal bar electronegative. In this case, too, an electrostatic counterforce will then come into play, and the difference of potential at the surface of contact will be maximum when this force has become equal to the difference between the solution tension of the metal and the osmotic pressure of ions in the solution. The difference of potential will obviously be the greater, the greater the solution tension of the metal and the less the osmotic pressure of its ions in the solution.

Finally, in the third case, viz., the case in which the osmotic pressure of the metallic ions exactly equals the solution tension of the metal, neither metal will dissolve nor ions precipitate, and consequently no difference of potential will exist at the surface of contact of the metal and the solution.

It may be objected that hypothetical views of this type may and may not be true, and this correctness cannot be expected to be amenable to experimental test. But Palmaer has succeeded in producing, to say the least, strong experimental evidence in their favor. Mercury, viz., is one of those metals whose electrolytic solution tension is very slight, and even in contact with a weak solution of one of its salts it becomes positively charged, mercury ions precipitating themselves upon the metal from the solution. Palmaer placed some metallic mercury in a vessel and covered it with a fairly tall layer of a weak solution of mercury salt. Into this he allowed to run from above a steady stream of droplets of mercury from a dropping funnel. Each droplet took up mercury ions in the upper part of the solution and carried them along, but had to give them up to the lower part of the solution when it joined the body of metallic mercury at the bottom of the vessel, for this body soon became overcharged with positive electricity. The lower part of the solution thus becoming positively charged, while the upper part became negatively charged (owing to loss of positive mercury ions), negative ions migrated from the upper part downward, and in this manner a real transportation of the mercury salt as a whole took place. Palmaer was able to show, by actual analysis of different layers of the solution, that the lower layers had become appreciably more concentrated than the upper ones, as was to be expected if the principles developed above were true.

Our principles permit of gaining a clear insight into the mechanism of electrochemical action. Take, e.g., again the Daniell cell, which consists, as we have seen, of a concentrated solution of zinc sulphate and a concentrated solution of copper sulphate, separated from each other by a porous partition, with a bar of metallic zinc in the former solution and a bar of

metallic copper in the latter (see Fig.). It will be seen in a later section of this article that the solution tension of zinc is very great, that of copper very small. Some zinc will therefore enter the solution in the state of positive ions,

DANIELL CELL.

which will render the zinc solution electro-positive and leave the zinc bar electronegative. On the other hand, a number of copper ions will join the copper bar in the state of metallic copper, rendering the bar electropositive and leaving the copper sulphate solution electronegative. Equilibrium will ensue when the excess of solution tension in the case of zinc and the excess of osmotic pressure in the case of copper are exactly counterbalanced by the electrostatic forces as explained above. Now, if we should then connect the two bars by means of a metal wire, a flow of electricity (positive electricity from copper to zinc, negative from zinc to copper) would take place between the two bars, and thus the equilibrium would be destroyed. Freed from the electrostatic attraction, the excessive zinc ions of the zinc sulphate solution would migrate towards the excessive negative ions of the copper sulphate solution. At the same time more zinc, driven by the unchecked solution tension, would go into solution, and more copper ions, driven by the unchecked osmotic pressure, would be precipitated upon the copper bar. If we should break the connection between the bars, the former equilibrium would soon be re-established, and chemical action would cease. But as long as the connection exists, zinc goes into solution, copper is precipitated, and a current of electricity passes through the connecting wire; we say, "electrochemical action is going on."

Suppose, now, that the copper sulphate solution of the Daniell cell were replaced by a solution which could take up molecules from the copper bar, but in which those molecules, instead of being transformed into ions, would form a practically undissociated compound with some other ingredient present. The osmotic pressure of copper ions would thus be extremely slight and might be exceeded by the electrolytic solution tension of copper, in spite of the latter being comparatively small. It is therefore easy to see that under certain conditions it might be possible to reverse the electrochemical process of the cell. As a matter of fact, this is precisely what happens when the copper bar of a Daniell cell is immersed into a concentrated solution of the cyanide of potassium. On closing the circuit copper then goes into solution, zinc is precipitated, and the direction of the current is reversed. This and similar phenomena were formerly described as "anomalous," because they seemed

to contradict the assumption that zinc has a greater "affinity" for acids than copper. Substituting the definite concept "solution tension" for the vague concept "affinity," and adding the factor of the "osmotic pressure of ions," we experience no difficulty in understanding effects like the reversion of current in the Daniell cell by potassium cyanide and many other phenomena. And it must be observed that the osmotic pressure of ions is a measurable quantity (see SOLUTION; DISSOCIATION), and that the solution tension of metals, too, has now been calculated from directly measurable quantities. See further below.
